## General Remarks

ON THE

## PRACTICE OF MEDICINE.

BY

P. M. LATHAM, M.D.

THE HEART AND ITS AFFECTIONS, NOT ORGANIC.

### I.—General View of the Subject. *The Pulse.*

It is always desirable to trace out the just limit of a subject, and to note the right places within it for all known facts; and also where kindred facts, hereafter to be known, may take up their places beside them. This I some years ago sought to do, as far as my observation then enabled me, for the subject of diseases of the Heart (*Lectures on Clinical Medicine, comprising Diseases of the Heart*). It was a sketch only that I attempted. But the facts there considered, numerous as they are, and facts of the like nature hereafter to be known, numerous as they may be, would go to make up a part only of the entire subject. My concern was with structural diseases and disorganisations of the heart; and the facts brought under consideration went to denote them in their kind and in their seat, whether beginning or progressive, stationary or receding, curable or incurable; also their causes, consequences, and events.

But there are numerous facts, unquestionably belonging to the pathology of the Heart, which are of another kind, and which cannot be made to fall within the assigned limit. Therefore we must enlarge its boundaries, that nothing may be excluded which is found legitimately to belong to the subject.

In every organ of the body, and preeminently in the Heart, the living actions and sufferings of disease have a compass and a reach far beyond its material framework; and not only beyond it, but independent of it. Excess and defect in the force of the Heart's impulse, excess and defect in the number of its beats; also derangements of their natural order and sequence, and the same made perceptible in the arteries; also varieties of morbid sensation immediately referrible to its seat, from a mere sense of weight and oppression to acute and agonising pain: any of these may exist alone, or a few or many of them in combination, and yet the Heart be perfectly healthy and sound of structure.

But the Heart must act thus and suffer thus from some vital necessity, although that necessity be not demonstrably inherent in its own structure. And not being in the Heart, where is it and what is it? These truly are the very objects of inquiry. Such affections have been denominated nervous and sympathetic. But to call them nervous would seem to

imply that they all belonged to one pathological category: and this is certainly not the case. To call them sympathetic, if the term be not taken in any strict sense, would be less objectionable. But if we so designate them, we must be allowed to embrace more than is usually included under that title.

The Heart passes for the most sympathising organ in the body. And it may be really so; or it may be that it does not in fact sympathise more than other organs, only more apparently. For who shall say that every part of the body does not sympathise with every other part, and that its functions are not put out of sorts by every other's detriment or disease? But the functions of many parts are hidden functions, and we know not how it may be with them. Yet the functions of others are apparent enough; of those, for instance, which secrete; and we know that their secretions are ever apt to be altered and vitiated, not merely by diseases of their own, but by diseases, small and great, beginning and ending in other parts, and altogether restricted to them. And so, too, of the heart: it cannot beat a beat too many, or too few, or too strong, or too weak, without its being straightway perceived; and thus we become convinced that it has as many modes of abnormal action derived from diseases without as from diseases within itself.

But it is not enough that sympathies and sympathetic disorders should be admitted as bare realities. They must become objects of familiar knowledge, if the physician is to make any safe use of them for practical purposes.

There are sympathetic affections of the Heart so constantly found in company with certain conditions of disease in the constitution at large and in particular organs, that they have seemed to be naturally annexed to them, and have come to be ranked among their symptoms, and taken for proofs of their existence, and for guides of their treatment. Such are the greater force and frequency of the Heart's action in fevers and inflammations. A fever is hardly thought to be a fever, or an inflammation to be an inflammation, without them. Nor are these sympathetic affections of the Heart barely *annexed* to such conditions of disease. They are often found to keep exact measure with them. Degrees of frequency and force in the action of the Heart and arteries, and their variations from time to time, follow degrees and variations of febrile and inflammatory movements, as they increase and decrease and rise and fall, and so give notice of their incidents and tendencies and events; moreover, of what they need and what they will bear, for cure or palliation or safe conduct.

Again, there are sympathetic affections of the Heart found in company with certain conditions elsewhere, yet neither constantly so nor in all persons, but occasionally and seldom, and in a few. They look like mere casualties, if such things can be.

Or if they come from a real physical necessity (as indeed they may), that necessity does not grow out of the nature of the disease, but out of the constitution of the individual man who suffers it. Such are the palpitations of the Heart and the irregular and intermittent pulse, which sometimes go along with disorders of the digestive and assimilative functions; which attend states of plenitude and emptiness of the blood-vessels and morbid qualities of the blood itself; also which are found in nervous and mental maladies. Of all these I will not say that no orderly account can be given, only that they can hardly be made out to follow exact rules. Nevertheless, they demand careful consideration; for when they come to be viewed in their instances and examples, then will appear their great importance. They will not, indeed, be found to claim the rank and value of symptoms, because their alliance with the diseases which they accompany is occasional only and extraordinary. Nevertheless, what is occasional only and extraordinary is sometimes as a light let in from a new quarter, and bringing into view what would otherwise have lain hid. And thus these unwonted sympathies of the Heart denote a possible reach of diseases beyond their common range. Pointing to things which come to pass beyond our thought and reckoning, they serve to abate our wonder at the strange turns and issues of even common diseases, which have taken the wisest and most experienced by surprise.

But sympathetic affections of the heart, in their wide range and in their multitudinous forms and instances, have a very unequal interest. As there are some which cannot be made too much of, so there are others which cannot be made too little. What can be said of palpitations of the heart, and intermissions, and irregularities of its beats, which come and go during a man's whole existence, neither originating in any known disease, nor terminating in any, nor abridging in any measure the duration of life. They must come from something, but we know not what. We may call them sympathetic, but it must be in a very lax sense.

There are diurnal variations in the state of the circulation which belong naturally to all men. In the great majority, they concern only the force and frequency of the heart's action, raising it a little and quickening it a little at different times of the same day. They must be owing to something, yet they are consistent with perfect health. But in some these diurnal variations go beyond the mere force and frequency of the heart's action. They go even so far as to disturb the rhythm and succession of its beats, making them intermit and flutter at different times of the same day. And these too must be owing to something, and yet they are consistent with perfect health.

The observations which have been made may at least serve to notify the extent of the subject in hand. They do not pretend to have done anything towards setting it in order. If inquiry into the sympathetic affections of the heart is to be fairly and fully carried out, it must begin with those which are the most common and the most constant, and so pass from them to those which are more rare. It must start from the well observed varieties of modes and degrees of action in the heart and arteries, which experience takes and uses as its every day index of diseases and its every day guides to practice. The

elements of the whole subject are to be found in the Doctrine of the Pulse.

Before we proceed, let us just consider the stand-points from which we must needs make our survey. There is no organ of the body which during life submits its structural condition so freely to our knowledge as the Heart. Of the changes it is capable of undergoing, from age, from accident, or from disease, it is remarkable how many may be fairly reckoned within reach of our diagnosis; its bulk, whether great or small; its consistence, whether hard or soft; its cavities, whether dilated or contracted, and even which is dilated and which contracted; its orifices, whether free or straitened, and even which is free and which is straitened. All this knowledge is put within our reach by auscultation and the stethoscope. Without them it would be unattainable, and with them it is only attained after a world of patience and industry and infinite trials and experiments. Difficult, however, as it is to get, it is pretty safe and sure when we once have got it. Another circumstance, which greatly helps to make our knowledge of the heart's structural diseases among the surest knowledge we possess, is that their immediate effects upon the organ itself, as well as their distant effects throughout the body, result in a great measure from mechanical necessity. Hence there is a good deal in every case which can be reckoned with much exactness. But it is far otherwise when the Heart being sound of structure is functionally deranged. All that then arises must come from vital necessity. All our reckonings are then made from other points of view, and by other means and instruments, and with less certainty.

Well, but the elements of the subject are then, it has been said, in the Doctrine of the Pulse.

There is not any disease, great or small, in any part of the body, vital or not vital, which the physician does not think to know better than he would otherwise know it, and treat it better than he would otherwise treat it, by interrogating the pulse. The information he thus gains is sometimes much and is sometimes little; but very seldom indeed is it none at all. To be fully aware when it amounts to much, or little, or nothing—that is, to appreciate the pulse at its true worth—is among the chief concerns of medical practice. Very seldom, indeed, I repeat, does the pulse convey no information at all. Even when amid a complex of symptoms, it remains just as it is in health; yet, negative sign as it then is, does it often become, under the circumstances, more pregnant of meaning, and give surer notice of what is going on, and of what should and what should not be done, than the most positive fact among them all. The pulse remaining steady to the force and frequency of health is often the very thing that is wanted to interpret a crowd of urgent and doubtful symptoms; to stamp them all with their true value, and make them pass just for what they are worth. Thus, an appeal to the pulse is indispensable in every case. There is no getting on safely without it.

But the Heart is the prime mover all the while; and the heart is so far the *pulse*. By its all-permeating sympathy, it feels all that is hurtful throughout the body; and by its own peculiar mode of action it tells all that it feels, and telegraphs intelligence of it through every artery that can be felt.

The Heart using its proper language of sounds and impulses, how clearly and emphatically does it speak of its own diseases to the ear and touch of experience. Then the complete information which we desire comes almost always directly from itself, and further appeal to the arteries is superfluous. On some rare occasions, perhaps, the heart's direct language concerning its own diseases may not be so absolutely indubitable, but that it may gain clearness and explanation by what is further spoken through the arteries. But the converse of this comes to pass when the Heart is perfectly sound, and when it has nothing to tell of itself, but a great deal to tell of every organ and system of organs in the body beside itself, and of all diseases everywhere beyond itself and out of itself. Then its most frequent, precise, and trustworthy intimations are conveyed through the arteries, its own direct sounds and impulses being but of rare and occasional use and significance.

It requires some courage to talk gravely and with a purpose of instruction about common things. For either people do not listen at all, expecting to hear nothing new; or they listen reluctantly, not liking to be schooled about what they understand perfectly (they think) already. And if there be any one thing which medical men may be thought to understand better than another, and to have, literally and in every sense, at their fingers' ends, it is the pulse. And yet I am about to take upon myself to speak even to medical men about the pulse. It lies, indeed, at the very root of my subject to do so. But apart from this formal consideration, I am persuaded that I should be rendering an useful service to my profession if I could speak of it as I desire. I conceive that this same lamp, which we all familiarly use and trust to guide our daily path, may still be placed in a better position, and thence be made to throw a more certain light upon the great objects of practical medicine.

All that can be known concerning the pulse, we learn either by attending to each separate beat, or to several beats in succession. By attending to a single beat we learn whether the pulse be hard or soft, large or small, that is, its qualities. By attending to many in succession we learn whether it be frequent or infrequent, regular or irregular, or intermitting, that is, its number and its rhythm. And it must be obvious that its number and rhythm alone can be submitted to actual measurement, and that all the rest, the qualities namely of each particular beat, is to be determined by the perceptions of the person who feels it. But men's watches agree better together than their perceptions. Looking to our several watches, we have an index as nearly uniform as possible, and so we are always of one mind about the number of the pulse and its rhythm. Consulting our several perceptions, we use a variable index; and no wonder that about the *qualities* of the pulse we are apt to differ. Yet, after all, practical men are found to agree pretty well about the quality of the pulse in particular instances. And it is because they consult it with no purpose of refining, but with the single aim of finding in it something to help them in their knowledge and treatment of disease. This single aim is mine. Therefore, in every part of the subject, and above all in this, which is naturally open to refinement, I shall avoid new names and new distinctions; for I

know full well that if I cannot handle the subject with simplicity I shall make a puzzle of it. Let us, then, first consider the number of the pulse, whether it be frequent or infrequent, and the succession of its beats, whether it be regular or irregular, and afterwards the qualities of the pulse, whether it be hard or soft, large or small—in fact, these are all the distinctions which I wish to insist upon.

Let me add a single remark, lest I should seem to affect an over-simplicity. It is one thing for a man to understand a matter for himself and for his own use, and another thing to understand it and explain it for the use of others. Therefore, I would not exclude a regard to other modifications of the pulse (whatever they may be), which any man's own observation may have taught him, and which he may have used for guidance and direction in the management of disease. There may be many such with which I have no acquaintance. Still, since there are things which practical men often know assuredly, and employ successfully, yet of which they cannot convey to others either the knowledge or the use; and since this is especially true of our present subject, I would willingly avoid those parts of it which, whatever I may fancy myself to know, I am still incompetent to explain.

THE SUMMER OF 1862. The registrars for England and Scotland report that the highest temperature recorded last summer at any of the stations from which returns are made to them was 84.5° in England, and 80.5° in Scotland. In such returns the difference of temperature in places at no great distance from each other is very remarkable. In May last the thermometer was at 81.5° at the Royal Observatory and only 74.6° at Guildhall; 75° at Bournemouth, and only 66° at Ventnor. In July also, when the wave of heat again passed over England, the reading was 80° at Cardington, and only 70.5° at Aspley, in the same county of Bedford; 84° at Downside College, near Bath, and but 74.2° at Clifton. At the Royal Observatory the mean amount of cloud was 7.8 (of 9) in the three months April to June, and 7.3 in the three months July to September. The mean of 55 stations in different parts of Scotland shows that in the six months April to September the sun shone for only 1,052 hours, which is less by 128 than the average of the preceding six years. The amount of sunshine in the summer was almost the least ever known, says the Registrar-General of Scotland, and the amount of cloud the greatest; and these two things have held so remarkably as the rule for the last three years as to be confirmatory apparently of Sir J. Herschell's suggestion, that our seasons experienced a disturbance from a cosmical influence in 1859 from which they have not yet recovered. The amount of ozone varies greatly. It is very small in the metropolis: the mean of each quarter of this year has ranged from 0.2 at Camden Town in the first quarter to 2.1 at the Royal Observatory in the same quarter. At the coast and at some inland stations the mean has been as high as 5, 6, and 7. There are varieties such as these in the mean of the very last quarter; 0.7 at Downside College, Bath, and 5.7 at Clifton; 0.3 at Cokermonth, and 7.9 near Silloth. At Bournemouth, again, above 5 in the first and second quarters of the year, and not much above 4 in the third: at Worthing, on the same coast, 4.6 in the first quarter, and above six in the second and third. A few instances will show the variation in daily range of temperature; the mean in the last quarter was only 8.9° at Scarborough, 9.1° at Ventnor, 9.3° at Aspley, and at Bournemouth it was 17.7°; at Aldershot, 18.8°; at the Royal Observatory, 19°; at Leyton, 20.1°.

### DYSCHROMATODERMA; OR, DISCOLOURATION OF THE SKIN.

By ERASMUS WILSON, F.R.S.

CHROMATOGENESIS, or the production of colour, is an animal function enjoyed by the skin, in common with certain other of the organs of the body; for example, the eyeball, the liver, the lungs, etc. It is the source of the varieties of tint which are met with in the human race; which distinguish the Ethiopian, the American Indian, the Mongolian, the Caucasian, and the Albino; and, like other functions, it is subject, besides its physiological variations, to changes which are of a pathological nature, and which constitute the so-called "disorders of the chromatogenous function."

The disorders of the chromatogenous or pigmentary function of the skin, giving rise to dyschromatoderma, are all represented by the four colours—black, white, yellow, and blue, and the combinations of black and yellow constituting the various tints of brown.

Black is the archæus of melanopathia, melasma or nigredo cutis, ephelis, and stearrhœa nigricans; while the absence of black constitutes leucopathia, leucosma or aliphosis, and albinismus. Yellow is represented by lentigo, flavedo cutis, and stearrhœa flavescens; and the blending of black and yellow gives rise to the various hues of chloasma and fuscedo cutis; the yellow and the black together sometimes producing a greenish tint, as in certain varieties of chloasma and lentigo. The presence of blue pigment in the skin, constitutes the cyanopathia cutanea of Billard d'Angers.

Melasma or nigredo cutis (nigrities) has of late attracted some notice in consequence of the researches of Addison and others; it has received the additional synonym of "bronze skin"; and, possibly, some further observations on this morbid state may not prove uninteresting to those who have given their attention to the subject or are seeking information with regard to a very curious but not very rare pathological phenomenon.

The main points that I propose to illustrate in this essay, are: Firstly, the existence of a peculiar form of anæmia, which may be termed melanæmia, in association with melasma; secondly, the origin of melanæmia and melasma in debility and exhaustion of parts of the nervous system; and, thirdly, to deduce from these premises a principle of medical treatment.

Anæmia is practically a deficiency of the red element of the blood; but, besides the red element, the blood is known to possess a yellow colouring principle, and, probably, a black colouring principle. Under the influence of certain physiological or pathological operations, these three principles may undergo changes—changes of quantity and intensity; and accompanying these changes the anæmia may assume a diversity of complexion. The anæmia may have a colourless character, leucanæmia; it may have a yellow and greenish tint, chloranæmia; or, as I shall endeavour to show, it may have a blackish hue, and so give rise to a form of anæmia which I have commonly observed in relation with melasma and the melasmic diathesis; and which is accurately described by the term melanæmia.

The diagnosis of anæmia is generally determined by the appearance of the skin, of the mucous membrane of the mouth, of the gums, and especially of the conjunctiva; and according to the extent of deficiency of the red principle of the blood, will be the degree of blanch-

exist every shade of variety of degree of anæmia, from the merest indication of that state to the most confirmed bloodlessness.

So in melanæmia, the anæmia may be slight or strongly marked; and the peculiar darkness of hue which the eyeball acquires, may be scarcely apparent, or so striking as to attract the attention of the most cursory observer. In melanæmia, the mucous membrane of the mouth generally presents no differences from the ordinary appearance of anæmia, nor in many instances does the conjunctiva; but the especial sign of melanæmia is, a vivid brightness, a brilliancy, and sparkling lustre of the eyeball, a liquid depth of colour of the humours of the eye, and a strongly contrasting whiteness of the scleroticæ, the effect being often increased by a more or less deep tint of a dull blackness of the integument of the eyelids, more especially of the fold of skin of the upper eyelid which immediately borders the eyelashes. It is difficult to convey in words an appearance which is only recognisable to the observer as the result of close attention, and which can only be distinguished by careful comparison with the normal standard. But, in a well-marked example, there is no fact in medicine more demonstrable than the melanæmic or melasmic eye, not only in association with melasma of the skin; but, also, independently of the latter affection.

The melanæmic or melasmic eye is sometimes the only sign of anæmia which can be discovered in the individual, who, possibly, regards himself as in perfect health; but where it exists, it may be looked upon as indicating a predominance in the blood of the melanic principle, and a predisposition to melanæmia and melasma; in a word, it manifests a melasmic diathesis. On the other hand, melasma may exist without this symptom of melanæmia being present; apparently, because, in the latter instance, the colouring principle finds a natural outlet through the skin, and the melanopathia its special field of development in the cutaneous tissue; or, perchance, the abnormal pigment may at the same time be eliminated from the blood through some other emunctory organ.

It will be seen by these observations that I look upon melasma and melanopathia, not as a substantive disease, but as depending upon an altered state of the blood, a cacochymatous or dyscrasic condition of the blood, in which there exists a deficiency of the red principle and an excess of the black pigmentary principle; not, possibly, in the precise form which it afterwards assumes in the cells of the rete mucosum, but in that more elementary and diffusible shape in which it is first generated and held in solution or suspension in the vital fluid.

The term melanæmia is one of recent origin and was intended by its first author to signify the actual presence of pigment in the blood, as demonstrable by the microscope. To determine the diagnosis of melanæmia, therefore, according to this view, it becomes necessary to be provided with the appurtenances of science, and moreover with leisure. A portion of blood must be taken; it must be properly diluted; it must be disposed on a suitable slide; it must be attentively examined; and then, the important fact is demonstrated of the presence of pigment, it may be in the form of granules or perhaps in that of cells or scales. But it is clear that this process so valuable in our schools of pathology—namely, our hospitals and infirmaries—is inapplicable to the daily routine of medical life, and that melanæmia as a demonstrable fact must be regarded as a scientific curiosity, comparatively unapproachable by the physician or the surgeon engaged in active practice.

But the term melanæmia, as used by me, has a different signification from that described above, and is intended to point out a clinical sign which may be tested by every one, and by which the presence of pigment in the blood may, as I believe, be as certainly determined as by the actual physical examination of that fluid. This clinical

sign is the melanæmic or melasmic eye already mentioned, and which I regard as an unfailing indication of a melasmic diathesis.

For a comprehension of what is included by the term melasmic diathesis, we are indebted to the researches of Frerichs of Berlin. Dr. Frerichs has shown that the blood of the spleen, as a consequence of retardation or torpor of its venous circulation, passes into a state of partial coagulation, and that the red corpuscles, at the same time, by a process of morbid chemical metamorphosis, are converted into pigmentary matter. The pigmentary matter is discoverable, with the aid of the microscope, in the form of free granules, and of cells and scales containing pigment-granules, and bearing in themselves the evidence of being altered blood-corpuscles. It is found in the blood of the splenic and portal vein, and may be traced thence through the pulmonary vessels into the general circulation. It is not improbable that any cause capable of producing torpor of portal circulation may give rise to similar results, and that the melanæmic or melasmic eye may in this way become an important sign by which the diagnosis of disorder of the abdominal organs may be determined when no other apparent symptom exists.

Dr. Frerichs has also shown that the pigment-matter may be detected in the lobules of the liver, and that its presence there occasions certain morbid phenomena. And that, next to the liver, it makes its way to the brain, and there gives rise to certain peculiar appearances and, doubtless, to altered function of that organ. And, furthermore, that it may, through the arterial current, reach every part of the body. The arrest of the pigment in the liver may, no doubt, in part, be mechanical; but its detention by the cerebral substance would seem to indicate an affinity between the nervous-matter and the pigmentary-matter, and suggest an explanation of the curious nervous and cerebral symptoms which are not unfrequently associated with melasma.

Another phenomenon will follow upon this; pigment-matter being proved to be actually present in the blood; the emunctory organs by which it is naturally eliminated will be excited to a more active secretion; the rete mucosum will receive a larger share of the pigment-pabulum; and the colour of the skin will be consequently deepened, either generally or partially, in obedience to other physiological and pathological laws. The tendency of the pigment-matter to seek the brain is a curious fact, and suggests the idea that this election may explain the early suffusion of the eyeball with the pigment, and the occurrence of the melanæmic or melasmic eye, when no other outward symptom of melasma is present. In observing this peculiar eye with attention, it has seemed to me that the choroid coat of the eyeball was more deeply pigmented than usual; that this extremely deep tint threw a stronger shade of blackness on the humours, and was the origin of part of the vivid brilliancy of the eye; and that, moreover, the extreme depth of black of the pigmentum nigrum was perceptible through the tunica albuginea.

But the melanæmic or melasmic eyeball looks as if it were suffused with a transparent pigmental fluid; or I might compare its appearance to a pure white seen through a black tinted glass; suggesting the idea of the black pigment being in the state of solution in the blood and in the fluids derived from the blood, as well as being corporeally visible in the shape of granules, as already described. Indeed, it is evident that the pigment, to be secreted by the skin, must be in a state of solution. This solution may be, and no doubt is, in part, supplied by the pigment-granules; but there are, besides, other soluble pigments, no doubt formed during the metamorphosis of the red corpuscles of the blood.

The origin of pigment by the metamorphosis of the red corpuscles of the blood explains the association of *anæmia* and *melasma*; and the presence of the melasmic

or of the melanæmic eye becomes the proof that the change which has taken place in the blood is not, as in leucæmia, the reduction of the normal proportion of hæmatine and the development of white corpuscles, but the destructive metamorphosis of the red corpuscles (*hæmic dyscrasis*) and the conversion of the hæmatine into a melanic pigment. What the true explanation of this curious change in the economy may be, whether it depend upon physiological conditions or a more or less intense pathological action, is not at present easy to decide; but of two facts I have satisfied myself—namely, the frequent association of morbid nervous phenomena with melanæmia, and a greater difficulty in restoring the normal condition of the blood than in ordinary leucæmia.

As may be inferred from these observations, the melanæmic eye is far from being uncommon; I have seen it three or four times in the course of a morning's duty. But *melasma* is comparatively rare. The melanæmic eye indicates a melasmic diathesis; that is to say, that state of the constitution in which there exists a tendency to torpid or obstructed circulation of the portal vessels, with a disposition to the metamorphosis of the red element of the blood-corpuscles into pigment. It is always associated with the common signs of *anæmia* to a greater or lesser degree, with more or less debility, and commonly with symptoms of dyspepsia, often with nausea and weight or oppression at the epigastrium, and sometimes with slight cutaneous disorder or other affection of the economy.

Let me cite a few instances, taken as they occur in my daily practice, as a further illustration of this phenomenon.

A young physician was introduced to me by his friend to ask my opinion as to the best course to pursue in reference to practice. Our conversation ended, I demonstrated to him the melasmic eye, of which he was, unknown to himself, the subject. Like all aspirants for medical honours, he had been working too hard; he had lowered his nervous tone. His digestive powers had suffered in consequence. There was, doubtless, torpor of circulation in the portal system, and the consequent development of pigment in the blood, or *melhæmic dyscrasis*. His conjunctiva and tongue were slightly pale, and he had the characteristic black transparency of the eyeball. Both he and his friend recognised the melasmic eye; and I suggested to him, as a medicine appropriate for the removal of its cause, the nitromuriatic acid with tincture of gentian.

My friend F. brought to me his daughter, a little lady of nine years old, for a slight pityriasis of the scalp. I was glad of the opportunity of demonstrating to my friend the melasmic eye, which in this young lady was well marked; there was, besides, a slight but general sombre or ashy hue of the complexion which seemed due to a blending of black, yellow and blue, and a certain metallic polish of the skin. When she was seated by her sister, who was also out of health, the contrast was very apparent. There were no symptoms of ailment about the young lady that would have attracted attention but for the pityriasis; and for this alone she was brought to me. Her appetite was not quite so good as usual; but her father had not observed anything else.

A surgeon of eminence brought to me his son, suffering under a slight attack of leprosy *psoriasis*. The boy possessed a large cerebral development, was pale and thin and had the melanæmic eye of moderate intensity. His father told me that he had been to the sea-coast; but that since his return he had suddenly and unaccountably fallen off in strength, and that under the influence of this state of debility, the squamous eruption had appeared on his skin. My reading of the case was: Abnormal activity of an excitable brain induced by study, partial exhaustion of the nervous system by growth, and consequent debility of the organic functions; then, as

an ulterior consequence of lowered nervous tone and retarded circulation of the chylipoietic organs; hæmic-dyscrasis, assuming the melanic type.

The melanæmic or melasmic eye as a sign of aberration of health is a purely medical symptom; it is rarely or never so marked as to attract the attention of the patient; and it is therefore of the more importance that the medical man should be acquainted with it; inasmuch as it serves to denote the presence of a *causa morbi* in the economy; and, moreover, a cause which if not removed, may run on silently and insidiously and be productive of serious ultimate consequences.

In the preceding three cases I have alluded to three common causes of melanæmia; namely, exhausted nervous power from over study; altered nutrition accompanying the growth of the body; and weakened nutritive powers originating in the exercise of a morbidly excitable nervous system. I have also seen it associated with other temporary disorders of the economy, as in the following example. A veterinary surgeon consulted me for exfoliating maculæ on the palms of the hands, caused, as he believed, and no doubt excited by the use of a blistering fluid to a horse's legs. The eruption appeared immediately after rubbing in a quantity of this fluid and leaving it on his hands for some time afterwards. As I knew at the first glance that the eruption was syphilitic, I beat over the usual ground of symptoms, skin, throat, nerves, etc., but found no trace of a corroborating secondary symptom. I then pushed my inquiry home to the hair of the evil, and discovered a small red patch in the sinus præputii, and a little induration. He informed me that the chancre had been so slight that he had given it very little attention, and, not suspecting its nature, he had adopted no treatment whatever. It commenced nine weeks back, and the eruption on his hands two weeks ago. He had taken arsenic for the latter; and but for my diagnosis and inquiry, would never have connected the two disorders. This patient had a melasmic eye; but, as it had not attracted his notice, he was unable to tell me if it had shown itself before or subsequently to the chancre.

I could multiply these cases of melanæmic or melasmic eye, for they are very common, to an indefinite extent, but the enumeration would be little more than a repetition of the four cases already detailed. But I am not at present dealing with the question of the physiological origin and distribution of the pigment element of composition of the animal organism, but simply with its pathological origin. It seems to me not unlikely that the normal origin of the black pigment of the organism may be a metamorphosis of the hæmatine of the blood; but the abnormal source of the pigmentary element appears decidedly, as Dr. Frerichs states, to have this origin; to be in fact, a hæmic or melhæmic dyscrasis. The pigment principle is no doubt diffused throughout the entire circulation; and under the influence of the special conditions of the skin is developed in the rete mucosum as a pigmentary substance, and is regulated and controlled by physiological laws. But, when it is developed pathologically, its control by physiological laws is no longer possible.

To a process similar to that described by Dr. Frerichs as occurring in the spleen, but in a different locality, namely, the uterine veins, is probably to be ascribed the deep discolourations of the integument of the eyelids in menstruation. In a case of hysteria which once came under my notice, the black pigmentary secretion was eliminated by the skin of the eyelids in such abundance as to appear on the surface as a moist secretion that could be wiped away with a sponge. And the blood of this patient was so loaded with the pigmentary matter, that it was observed in the fluids which were thrown from the stomach by vomiting, in the egesta from the bowels, and in the urine. It is needless to repeat that, together with this destructive metamorphosis of the red

corpuscles of the blood, there was a deficiency of hæmatine to an extreme degree.

Recurring to the phenomena described by Dr. Frerichs, namely, the partial coagulation of the torpid stream of venous blood in the sinuses of the spleen; the decomposition and metamorphosis of the red corpuscles of these coagulated agglomerations into pigment matter, and the detention of the particles of the pigment by the liver, where they excite a variety of morbid processes; the question arises: Do not these changes take place even more frequently than Dr. Frerichs imagines? Do they not take a prominent share in the production of many of the disorders of daily observation? Are they not continually before us without attracting our attention? I think they do, and are; and I am led to this conclusion by the great frequency of the melasmic eye and its associated symptoms. Let me cite an example of everyday experience. A lady, of fifty, leucanæmic, complained to me of constant nausea, vomiting after every meal, frequent diarrhœa; a feeling of extreme uneasiness with weight at the epigastrium, and extreme languor and lassitude, with great weariness. I prescribed for her, quinine. A fortnight later I saw her again, and she gave me the following account of herself: "I felt," she said, "that there was something that required moving from here," placing her hand over the epigastrium, and including in its stretch a part of the stomach, the duodenum, and the central portion of the liver; "I therefore took four grains of blue pill at night, and the following morning a senna draught. The quantity of black offensive stuff that came away was quite wonderful, and my nausea, my sickness, and the uneasiness and weight at the pit of my stomach were immediately removed." Was not this a case of melasmic excretion from the liver? I must confess I thought so, and think so still. But, it may be suggested, this patient was leucanæmic: yes, she was so, as far as the eye and skin were concerned; but only because the melanic matter was all collected in the liver, where it had been detained by a process of filtration, and whence it was subsequently eliminated.

In further corroboration of this, the practical bearing of the subject, I may call to mind the constant accompaniment of nausea and an uneasy epigastric sensation with melasma; and the unshaken conviction of the patient that the liver is the source of the evils complained of. A lady whose case is reported (Case 1) remarks that a dose of calomel immediately dissipates her unpleasant feelings; that her complexion immediately becomes clear, and the melasmic blotches on her face less evident; and that, when she has failed to take the remedy, she has more than once suffered an attack of jaundice. And in truth, theoretically as well as practically, we must admit the capability of a dose of blue pill or calomel of disgorging the liver of its "atra bilis"—of its melanic accumulation—and of rendering more active and free the abdominal venous circulation.

Passing onwards to my second proposition—that melanæmia takes its primary origin in debility or exhaustion of the nutritive or trophic filaments of the nervous system, I must appeal for my illustration to the cases which I am about to report. I may observe that I have been led to this conclusion by the history of the patient, and by tracing the origin of the malady to its apparent source. It is remarkable that the subjects of melasma are, for the most part, of the female sex—of a sex in whom the nervous system plays a more conspicuous part than it does in man; that they range in age between twenty-five and fifty—a period during which the harsher realities of life are most pungent in their operation on the nervous system; and that, in almost every instance, an exciting cause may be found in injury done to the nervous system, either indirectly as an effect of some exhausting disease or organic lesion, or directly in the form of a sudden or violent shock.

The operation of the injury to the nervous system

would seem to be expended on the nutritive organs, with a consequent deterioration of their functions. The innervation and circulation of the chylipoietic apparatus is disturbed and impeded; nutrition is weakened; assimilation is imperfect; and cacoehymia follows; and with cacoehymia a want of the natural harmony of proportion of the different pigmentary principles of the blood. It may be that the red principle—the hæmatine of the blood—is chemically converted into the melanic pigment; or it may be that the melanic principle is simply a carbonaceous product resulting from the waste of the organic tissues.

In melasma, we find an illustration of a principle not uncommon in pathology; namely, the persistence of the local abnormal action of the part after the general economy is restored to health. It would seem to be the natural habit of the blotches of melasma to remain for years or for life, when a constitutional debility or a morbid cause capable of keeping them up can no longer be traced. And, in one of the cases reported in this paper, after the restoration of the patient to a better state of health, after the establishment of a healthier hæmatosis, and after the removal of the stains by local means, the general tint of the complexion acquired a deeper, but, at the same time, a distinctly healthier tone than before. My patient exchanged a complexion of a faded, patchy, muddy hue, for that of a handsome brunette, the tint of brown being richer and brighter than before, and suggestive of the idea of a more copious oily secretion being blended with the pigmentary secretion.

In another case, one of melano-leucopathia, which I published several years back (portraits), I drew attention to the curious results to the economy of a variation of the standard of colour of the skin. In this case, there were four shades of colour present at the same time, the natural tint, the leucosma, the general melasma, and the partial melasma. Nature had, so to speak, physiologically adopted these four tints, and the question arose: Which would she decree to be the proper standard when a process of restoration of the pigment in the leucosmic patches was established? I solved this question experimentally by inducing a restoration of the pigment secretion on the white patches, through the agency of a stimulant application; the colour returned on these patches. I had set the melanic machinery in motion; but how was I to control it? It passed the original normal standard; it went on, and it passed the deep tint of general melasma; it still went on, until it reached and almost exceeded the deepest tint of all, the partial melasma. Here, then, was an example, not of a natural standard, but of an acquired or morbid standard.

[To be continued.]

## COMPOUND COMMINUTED FRACTURE OF BOTH LEGS: DOUBLE AMPUTATION: RECOVERY.

By ANTHONY MARTIN, Esq., Evesham.

WILLIAM ROBBINS, aged 11, a spare, thin looking lad, came under my care on April 6th last, with the above accident. It appears that he was in the act of crossing the line of the West Midland Railway, to speak to his father, who was at the time engaged in loading a cart, when a luggage train, which was shunting goods, came on the line he was crossing, and knocked him down in the middle of the space between the rails, whence he tried to extricate himself; and, in so doing, got both his legs across the rail, and the wheels of six or seven trucks passed over them.

Upon examination, it was found that the right leg from the middle third to the ankle-joint was completely crushed, the large vessels and nerves ruptured, and the muscles in front and back of the leg totally destroyed;

the foot was wholly denuded of its integuments. The left limb was not injured so much as regards external appearance. The foot was completely crushed, but the integuments of the limb were whole, with the exception of an aperture high up close to the junction of the posterior tibial with the popliteal artery, from which considerable hæmorrhage was taking place, the artery being found to be ruptured. The soft parts of this limb were evidently much bruised as high as the middle third of the thigh. I adopted the circular incision in both instances, removing the right leg below the knee-joint in the upper third. There was considerable difficulty in tying the posterior tibial artery, from the unusual amount of retraction. The left limb I removed immediately above the knee-joint, on account of the division of the posterior tibial artery. No difficulty occurred in this operation; but the muscles were very dark, from the bruising before mentioned, presenting almost an ecchymosed appearance. The patient was put under the influence of chloroform.

Immediately on the completion of the operation, he was removed to the workhouse; the stumps were dressed with strapping and wet lint, a few points of suture being first introduced, and an opiate was administered.

April 7th, 10.30 A.M. He had passed a good night, and looked cheerful and composed. Pulse 110, and fluttering. He complained of no pain.

April 8th. The dressings were removed this morning. The general appearance of the stumps was good, though the soft parts of the left stump were much contused. Pulse 120, and very compressible. The opiate was repeated.

April 9th, 7.30 A.M. He slept well after the opiate; but the tongue was inclined to dryness. The bowels were freely relieved, and there was some discharge from the wounds.

April 11th. There was no apparent change, except that the left stump did not seem to be healing as well as the right.

April 13th. Some considerable bleeding took place in the night from the left stump, which looked gaping and sloughy. The last of the sutures was removed this morning. The pulse was much quicker, 135, and feebler. His appetite was good. Beef-tea and wine were given freely, and the opiates were continued.

April 19th. The left stump was still sloughy, discharging freely. Most of the ligatures on the arteries came away this day. The pulse was still very quick; it had not unfrequently been up to 150 since the last report.

April 22nd. There was slight improvement in the left stump. The sloughs had separated to a considerable extent. The pulse had diminished in frequency, though still very weak. The ligature from the femoral artery had come away this day. The wine and beef-tea were continued, with a mixture of cinchona and mineral acid.

April 30th. The general condition of the lad had greatly improved since the last note. The sloughs the left stump had been very considerable, and the bone was protruding, but the right stump had gone on remarkably well.

May 15th. The right stump was healed; from the left, about an inch of the femur was removed.

The lad is now perfectly recovered; but, from the severity of the case, it seemed desirable to publish a report of it. The only untoward circumstance was the extensive sloughing in the left limb; this was occasioned by the nature of the injury, which could not be accurately diagnosed before the operation. But, had it been foreseen, I should rather have risked the irritation of the gangrenous inflammation than have amputated the limb high enough to remove all the injured portion of the muscles.

## ON THE DEATH-RATES IN THE COTTON DISTRICTS.

By JOHN BEDDOE, B.A., M.D., Physician to the Bristol Royal Infirmary.

At page 6 of the last Quarterly Report of the Registrar-General occur the following observations, which may serve as a text for the present paper.

"It is right at the present time to guard against deductions from the returns of mortality which they do not justify. . . . The allowances may or may not have been sufficient in amount, but the returns of mortality furnish no evidence of the fact; they only show that extreme consequences of famine have not yet been manifested in Lancashire. . . . Recreation in the open air, moderation in meat and drink, and the due administration of domestic offices, are beneficial to health; but, if they have been compensation for the loss of wages, the tables above quoted are silent on the point. These tables prove that, under circumstances favourable to human life, the mortality in England was reduced last quarter, and that the districts of the cotton manufacture were not prevented by the distress from participating in the benefit; they cannot show that, if Lancashire had been prosperous, the health of its people would not have been still better, and a further reduction of mortality obtained."

Doubtless these remarks are made by the Registrar-General with the praiseworthy object of preventing the current of public and private charity from being checked by a partial consideration of the facts relative to the mortality in the cotton districts which appear in his own tables. While thoroughly sympathising with this object, I think that the Registrar has failed to seize the full meaning of the facts in question, and that it may tend most to the general good and the interests of sanitary science if their import be clearly pointed out.

For the purposes of this investigation, I have divided the unions of Lancashire into two, and subdivided them into five groups, taking as the leading principle in the arrangement the more or less intimate dependence of each on the cotton manufacture.

In the first class I have placed those unions in which more than one-fourth of the adult population, male and female, were, according to the census of 1851, engaged in the spinning, weaving, printing, and dyeing of cotton. These are, Ashton, Blackburn, Haslingden, Chorley, Bury, Burnley, Oldham, Preston, and Bolton.

In the second appear only Manchester and Rochdale, places in which the number of operatives employed as above is considerably less than one-fourth, but where the distress is great, and the rates are stated by Mr. Farnall to be heavier than in some of the preceding class—doubtless in part, at all events in the case of Manchester, from the fact that there are immense numbers of persons who appear in the census under various heads, but who depend more or less directly on the cotton manufacture for their means of living.

In the third are six districts, where less than one-fourth of the adult population are employed as above, and in none of which, so far as we can learn, are the rates heavy. Even in Wigan, the only one of the six in which we hear of much distress, they have not reached the proportion of five shillings. These are, Wigan, Chorlton, Salford, Clitheroe, Leigh, and Barton-upon-Irwell. I will call this, for convenience sake, the half-cotton group.

In the fourth are seven districts, which have little or no direct connexion with the manufacture; viz., Ormskirk, Preseat, Warrington, Fyde, Garstang, Lancaster, and Ulverstone.

The fifth group might have been classed with the fourth, but is sufficiently important and peculiar to form

a separate subdivision, including only Liverpool and West Derby, or the town and suburbs of Liverpool.

More clearly to exhibit the facts, I have constructed, from the data supplied by the Registrar-General, two tables, which are appended to this paper. In the one, I have calculated, for each district or group of districts, the rates of mortality in the summer quarters of 1861 and 1862; in the other, the summer of 1860 is also taken into account.

The summer quarter of 1862, as may be gathered from the words above quoted of the Registrar-General, was unusually healthy throughout the greater part of England. Cold summers almost always are so in this country; and September was the only month of the three constituting the quarter whose temperature reached the average. Accordingly, all the eleven registration provinces, except the metropolis, and most of the counties, exhibited a decline of the rate of mortality, as compared with that of 1861. If the whole county of Lancashire had merely participated in this general improvement, there would have been nothing very remarkable in the fact; and, at the first blush, the figures show little more; while they also show that, in the extraordinarily healthy summer of 1860, the death-rate in Lancashire, as over all England, was lower still. It is only when we come to divide Lancashire into two sections, on the plan above stated, that we arrive at the mark-worthy result, *that the whole of the decline in the county has taken place in the cotton districts*; while there has been a positive increase in the other or more prosperous group of unions. We find, moreover, that while in the latter the increase of mortality over the healthy summer 1860 is prodigious, amounting to 27 per cent., in the former the decline remains even on that comparison.

Proceeding further to subdivide these two groups into five, we find the facts continuing to tell in the same direction. In the summer of 1861, while all Lancashire was still prosperous, the death-rates increased pretty uniformly in the several sub-groups of districts, the increase varying only between 20 and 27 per cent., and being exactly equal in the cotton and no-cotton groups. This increase, then, might fairly be attributed to meteorological and other analogous causes operating on all alike. But in the summer of 1862 a great change has taken place. The meteorological causes of disease remain, as before, common to the county; but the previous concern in the fluctuation of the death-rates is altogether broken, and, instead of 120 and 127, the extremes are as wide apart as 92 and 132. What can be the disturbing elements? Are they connected with the consequences of the scarcity of cotton? The figures yield an unequivocal affirmative. The much-cotton groups give in 92 and 98; the no-cotton ones, 117 and 132; while the half-cotton group occupies, as, *ex hypothesi*, it should do, an intermediate position (109).

To test yet further the accuracy of the results arrived at, we may now examine the returns from those districts in other counties than Lancashire where the cotton manufacture is extensively carried on. Tested by the census reports of 1851, these appear to be Stockport in Cheshire, Todmorden and Saddleworth in the West Riding, Hayfield and Bakewell in Derbyshire, and Carlisle. In every one of these six districts there is a decline, and in most of them a considerable one. In Hayfield and Bakewell, indeed, the decline falls much short of that in the remainder of the county; but in Todmorden and Saddleworth it far exceeds the average of the West Riding; while the remainders of the counties of Cumberland and Cheshire yield a positive increase of mortality. On the whole, there are, in the five counties above mentioned, twenty-three which may be considered as cotton districts, and sixty-three which are otherwise. Of the former, only two—viz., Chorley and Clitheroe—or 8 per cent., present an increased death-rate; while, of the

latter, no less than twenty-four, or 38 per cent., are found to do so.

It may be worth while to point out that the distress which prevailed in Coventry, and the neighbouring unions of Nuneaton and Foleshill, two years ago, was observed at the time to be accompanied by a decline in the mortality. In the present year, Coventry, never fully recovered, has again relapsed into deep distress; and again the same coincidence appears.

All these facts are more clearly set forth in the sub-joined tables. On careful consideration, I can perceive no objection to their validity worthy of mention. It may perhaps be said that emigration may have diminished the population of many of the distressed towns, and thus lessened their death-rates. It is, however, highly improbable that such emigration can have taken place to any noteworthy extent: Haslingden is the only district where the local registrar takes any notice of it. The class most prone to migrate—viz., the young adults—is precisely that which always furnishes fewest deaths. Moreover, the rather high birth-rate tells strongly against such a supposition. The decline in the usually high marriage-rate, which in Blackburn, Ashton, Preston, and Hayfield is great, but elsewhere moderate, is, of course, due to the pressure of poverty and the gloom and uncertainty of the future.

It seems to me that from these data we are entitled to conclude that the partial stoppage of trade in the cotton districts was, during last summer, attended by a great diminution in the death-rate; and that of this diminution it was a remote or indirect cause.

The proximate causes could be better set forth, and their relative importance more accurately estimated, by one better acquainted with the country and people than the present writer. Some of them, however, I have no doubt, are those indicated in the notes appended to their reports by some of the district registrars. Such are the greater amount of fresh air and out-door exercise obtained by the factory operatives, the cutting off from drunkards and opium-eaters of the means of indulging in their vicious habits, and the greater attention and care bestowed on young children by their mothers, who, from the shortness of work, are kept at home, instead of deserting their houses for the mills. Possibly we may add to these the greater purity of the air, no longer sullied by the fumes which, in a manufacturing town, are thought to furnish the most palpable evidence of prosperity.

It is a subject of grave consideration how to mitigate, henceforward, the virulence of those physical and social evils which seem to be so interwoven with our manufacturing system that its sudden collapse wears in the Registrar-General's reports the aspect of a positive blessing. Happily, the days are long past when, in the interest of greed against health and life, the disgraceful opposition to the Ten Hours Bill was carried on. Much has been done by enlightened and benevolent manufacturers, in the way of improving the ventilation and arrangements of factories and schools, diminishing or counteracting the production of noxious dust, etc.; but much yet remains to be done in improving the physical conditions under which the cotton and other manufactures are carried on. Of the social evils connected with the system, those resulting from the employment of married women in factories are still more difficult to deal with, and more intimately connected with the prosperity of the trade; for so long as it flourishes and affords high wages to female labour, so long will the temptations of the factory attract mothers from their proper sphere—the home.

In conclusion, I must again caution the reader against drawing too hasty or too extensive corollaries from the facts which have been substantiated above. They show, it is true, that hitherto the effects of famine have not been experienced, except, perhaps, in isolated cases;

and that the comparison of the condition of the Lancashire folk, as it has been hitherto, with that of the peasantry of Munster and Connaught in the terrible years of the potato blight, is a gross exaggeration. But they do not prove that the bare subsistence, secured by the public bounty and the systematic and unwearied exertions of the relief committees to the great majority of the poor, which sufficed to preserve them from sickness during the summer, will carry them equally well through the damp, inclement Lancashire winter, when also the deficiency of warm clothing, unfelt in summer, may tell with deadly effect. Nor can we say whether the scanty subsistence, which is the habitual lot of large numbers of people in other and hitherto less prosperous districts, and serves to maintain in them a certain standard of health, may not in the course of time tell very unfavourably, and produce low forms of chronic disease, among the hitherto well-fed and comfortable operatives, overlookers, and shopkeepers of Lancashire.

TABLE I, exhibiting the Rates of Annual Mortality in the Summer Quarters of 1861 and 1862.

Districts, etc.	1861.	1862.	In-crease.	De-crease.
England .....	2,012	1,836		176
Lancashire .....	2,436	2,116		320
First group: Ashton, Blackburn, etc. ....	2,387	1,892		495
Second group: Manchester and Rochdale .....	2,920	2,176		744
Third or half-cotton group .....	2,266	1,960		306
Cotton Division .....	2,533	1,967		566
Fourth group: Prescott, etc. ....	1,932	1,820		112
Fifth group: Liverpool .....	2,624	2,768	144	
No-cotton Division .....	2,384	2,436	552	
Stockport .....	2,368	2,043		325
Rest of Cheshire .....	1,856	1,883	27	
Hayfield and Bakewell .....	1,956	1,768		188
Rest of Derbyshire .....	2,062	1,600		462
Tolmorden and Saddleworth .....	2,136	1,768		368
Rest of West Riding .....	2,138	2,056		82
Carlisle .....	2,070	1,865		205
Rest of Cumberland .....	1,762	1,782	20	
Coventry, Nuneaton, Foleshill .....	1,904	1,600		304
Rest of Warwickshire .....	2,010	1,912		98

TABLE II, exhibiting the Relative Proportions of the Mortality in Three Summer Quarters, that of 1860 being taken as the standard.

Districts, etc.	1860.	1861.	1862.
England .....	100	117	107
Lancashire .....	100	125	109
Cotton Division .....	100	125	99
No-cotton Division .....	100	125	127
Ashton, Blackburn, etc. ....	100	127	98
Manchester and Rochdale .....	100	123	92
Half-cotton group .....	100	120	109
Prescott, Ulverston, Fylde, etc. ....	100	124	117
Liverpool .....	100	125	132

EXTRAORDINARY SELF-MUTILATION. The woman, the subject of self-mutilation, the wife of a barman, named Jane Brickland, aged 38, for some time past had given way to drinking habits, and while intoxicated she deliberately chopped off her left hand and wrist. She then wrapped up her arm, and in proceeding to the University College Hospital she called in at the Lord Wellington, and, having taken some brandy, she walked into the hospital, and told the porter she had cut herself. Unwrapping her arm, she said she had left her hand at home; it was a beautiful hand, and she was sorry she had not brought it, as they might have put it on again. During the exhibition of the limb she maintained a remarkable degree of coolness. Mr. Gee, house surgeon, immediately attended, but he found it necessary to send for Mr. Quain, and shortly afterwards the arm was operated on. It is believed that the woman will recover. (*Express*.)

## Reviews and Notices.

**THE RENEWAL OF LIFE:** Clinical Lectures illustrative of a Restorative System of Medicine, given at St. Mary's Hospital. By T. K. CHAMBERS, M.D., F.R.C.P., Physician to St. Mary's Hospital, etc. Second edition. Pp. 420. London: 1863.

WE are told that "a rose by any other name would smell as sweet"; and, for the sake of the man who said it, will admit the proposition, though not convinced of its truth. There are, however, certain things which undoubtedly require distinct and particular designations; and we think we may fairly say that Dr. CHAMBERS has laid himself open to criticism in putting the title of "Renewal of Life" on the back of the book now before us. It is only fair to the buyer and reader of a volume, that its name should present some idea—more or less distinct—of the nature of its contents. A book is, in one sense, a commercial article, and should, therefore, be properly ticketed when exposed for sale; but who would ever guess the quality of this book from reading the title on its back? A spiritual minded person would, we suppose, seek in it an account of man's probable state in the next world. Poets might regard it as a poem on the return of spring:

"But oh! my country's wintry state,  
What second spring can renovate?"

Patriots would turn to it as to a treatise on the regeneration of the human race or on the rights of the sovereign peoples. Male and female octogenarians, inordinately fond of life, would snatch at it as for a recipe of an elixir of life. Botanists and agriculturists would smell in it a treatise on manures—the decay of animal and vegetable matters, and their conversion into new living structures. These, and a score more such fanciful ideas, would different people attach to the book with this title. But we venture to say that no living soul would ever guess that the volume in reality contained a series of capital clinical lectures delivered by Dr. Chambers to the students of St. Mary's Hospital.

Twenty-nine lectures, in fact, a *l'envoi*, and an appendix, make up the volume, of which we will say at once that the perusal cannot fail to be a source of instruction and pleasure to the medical student and the practitioner of medicine. Dr. Chambers's mode of instruction is happy; and his practical method of treating disease founded on common sense and science. If, therefore, we followed him along, through these lectures, in his descriptions of the practical applications of our art to the cure of diseases, we should have little more to do than to praise and to agree with him. His practice is, we believe, *au fond*, very much the practice, more or less pronounced, of all enlightened medical men of this time of day; and this practice he lays down before the student in a manner suggestive, happy, and philosophic. We accede this to his practical teachings—in fact, to twenty-eight twenty-ninths of his book—but, unfortunately, we must take strong exceptions to the remainder, the one twenty-ninth part of the same—to his opening chapter.

In this chapter, Dr. Chambers explodes theories and expounds a theory. He, properly enough, does not go so far as to trouble himself with the theories

of the ancients; they have been too often slain. But what he does is to tilt at what he calls "five principles very widely prevalent at the present day," which principles he "holds to be essentially erroneous and blind;\* viz., allopathy, homœopathy, evacuation, counterirritation, and stimulation." We need hardly add that a reformer who lays prostrate all the effete principles of his day, of course has a new system of therapeutics to substitute for them; and, in the present instance, it is one which Dr. Chambers "makes bold to call the 'Restorative.'"

Now, if we wished for a better proof of the evil results of seizing hold upon any one particular theory in medicine as a guide to the treatment of diseases, we should find it here; and we are surprised that so acute a reasoner as Dr. Chambers did not see the pitfall which he was digging for himself in starting such a narrow theory as the basis of his practice. The fate of the innumerable theories of the past which he himself tells of, as having died the death, should have taught him caution in fixing his faith upon a new one. Happily, however, as we have already said, Dr. Chambers is too good a practical physician to allow his theory to interfere with his practice. Thus, though he derides what he calls *allopathy*, he, nevertheless, does not despise the use of sudorifics, under certain circumstances, when the skin is dry; nor a purgative when the bowels are confined. Theoretically, he holds *evacuation* to be erroneous and blind; but when the "typh-poison" (as he calls it, and as he believes) is disturbing the stomach, he does not hesitate to evacuate it by an honest emetic; nor does he hesitate to practise evacuation by evacuating blood at the mouth of a vein, when occasion requires. *Counterirritation*, again, is a false and blind principle; but the practical thing implied in the term, we are happy to see, Dr. Chambers makes use of just like the rest of the world. He uses a blister; but gives a different account of its action. What is called *stimulation*, also, is right in practice, but wrong in its theory. Alcohol, people have wrongly thought, is in itself a giver of vital force; not so; it is an agent which helps us to get the vital force out of other articles. Stimulants, then, are rightly given; only the givers are theoretically wrong in the application. *Chemical systems*, too, are all wrong. But yet, like a practical man, Dr. Chambers does not hesitate to ascribe the use of hydrochloric acid (which he highly extols in low fevers) to its neutralising agency upon the "superalkalinity" or "sub-acidity" of the blood in that disease. Nor, *vice versa*, does he fail to connect the good effects of alkalis in rheumatic fever with a superabundance of acids, or a deficiency of alkalis, in the secretions.

Hence, then, as far as we can see, the terms allopathist, counterirritator, Brunonian, evacuator, iatrochemist, and so on, apply just as fairly to Dr. Chambers as they do to any other medical man. He uses the same remedies and treats diseases as all the rest of us do; only he gives a new name to his practice. We, of course, omit one of his false principles, homœopathy; upon which we shall have a word to say further on.

Let us glance at his theory. The five false principles referred to by Dr. Chambers are, he says, based

\* These are the words of the first edition. In this edition, instead of "erroneous and blind", we read "misleading".

upon a false foundation. They are based on the idea of disease being an entity, a positive existence, a *materies morbi*.

"Disease," says Dr. Chambers, "is in all cases, not a positive existence, but a negation; not a new excess of action, but partial death; and, therefore, the business of the physician is not to take away material, but to add; not to weaken, but to renew life."

Really we think we must misapprehend the meaning of Dr. Chambers, or we could hardly have believed his worship of a theory could have led him to dogmatise in such a fashion as to make his practice distinctly contrary to his theory. Surely it is mere confounding of terms to say that disease has no positive existence. Why, what is the typh-poison but a *materies morbi* of which Dr. Chambers tells us? It goes down, he believes, with the saliva into the stomach; there, perhaps, grows and multiplies, and enters the system through the digestive canal.

"At an early stage, even after the poison has begun to act upon the system, the fever may be arrested by emptying the stomach, and thus, apparently, preventing the whole dose being taken up."

Dr. Chambers may, perhaps, say the typh-poison is not the disease; that the disease is the morbid action which the typh-poison sets up; but this is not the way (as we see) that he deals with the matter practically. He attacks the typh-poison in the stomach as a veritable entity; and so also would he attack the poison, which, when it has entered the blood, is producing the phenomena of fever, if he could. Of course, we all fully understand that there are here two distinct elements of treatment to be considered: First, the neutralisation or elimination of the poison, if so it may be; and secondly, the restoration to health—to their natural condition—of the parts injured by the presence of the poison.

This typh-poison is surely here practically just as much a positive existence as is the thorn in a man's flesh. The thorn excites inflammation; the typh excites fever. You remove the thorn, and then that diseased condition which has been excited by it gradually disappears. Dr. Chambers evacuates the stomach of its typh-contents, and cuts short the fever. Of what avail is it here to say that the disease has no positive existence?

Dr. Chambers has in all this evidently confounded the exciting agent of disease with the effects which it produces in the body. No one, of course, pretends that he can eliminate the *effects* produced by the poisoning typh—i.e., the alteration of fluids and structures resulting from its action.

The pathological teaching of the last thirty years at least has taught us that, when the fever has got possession of the body, we have but one duty to perform; viz., to guide the weakened organs and assist the injured body through the struggle of disease back to health. We have certainly understood for many a long year past that all diseases were signs of weakness, and that the duty of medicine was, by its aids, to restore (if so it might be) the body back to health. Surely, therefore, Dr. Chambers need not have claimed, at this time of day, the title of restorative for medicine.

Hence, the term Restorative Medicine is a contradiction, or rather a violent pleonasm; the practice of medicine being actually and truly the practice of the restoration of the sick body to health. We dis-

tinctly object, moreover, to being called allopath, or evacuator, or iatrochemist, or any other such one-sided name; and we equally object to taking the new title which Dr. Chambers offers us; viz., that of restaurateurs, restoratorists, or revivalists. To all such titles we enter a decided protest; boasting and claiming to be simply medical practitioners, as Hippocrates was before us, tied by the leg by no one therapeutical theory whatever; because medicine, being yet but an experimental art, is incapable of yielding any one rational theory which shall fit all our wants. In fact, we evacuate, we stimulate, we purge, we bleed, we blister, we counterirritate, because we learn from experience that these agencies incidentally assist in restoring to health the diseased body. We do all this just as Dr. Chambers does; and we affirm that this is neither allopathy, nor homœopathy, nor stimulation, nor any other of those "blind and erroneous" modern principles of action which he repudiates; neither is it restorative medicine, which he would call it. It is simply the practice of a reasonable medicine.

Dr. Chambers will not be surprised that we have a word to say to him on his mode of dealing with homœopathy. He is aware that we hold very distinct opinions on that subject. He objects to the "denouncing and deriding the practice of homœopathy." Denunciation is not argument; and the subject of human life is too serious for ridicule." And he maintains that "the promulgator of such a doctrine could logically demand that the experiments on which it be based should be tried." But surely Dr. Chambers has satisfied himself of the absurdity of this doctrine. Surely he must know that the experiments he asks for have been tried and tested fifty times, over and over again; and their utter fallacy demonstrated.

Dr. Chambers, again, must know that of the persons calling themselves homœopaths in the present day—most of them, at least—practice medicine just as he does, use the same remedies, and give the same doses. And yet he recommends the students he addresses to try these homœopathic recommendations for themselves, and watch their results. See, he says, if quinine will stop ague. Try if arsenic will beget psoriasis, or iron anæmia. "The action, also, of infinitesimal doses may be tried upon malingerers and 'hospital birds' who occasionally sneak into our wards." "Minute quantities of digitalis or saltpetre ought to diminish the daily secretion of urine," etc.

Now, we enter a distinct protest against his recommendation. We say that there are things concerning which he has a right to ask the student "*juvare in verba magistri*." We say, that there are so-called systems or systematised farces, which it is not only idle but wrong to recommend to the serious consideration of students. But why, above all, on his own principles, recommend the ingenious minds of the students to occupy time in experimenting on this particular one of the five modern principles which he denounces as "blind and erroneous"? Surely this is illogical.

Homœopathy, universally condemned, and practised by no member of the profession who is known as a man of science beyond the street in which he lives, a senseless and baseless delusion, has no kind of claim to the student's attention. If the medical student is to be told to try for himself the empty

ness of homœopathy, why not recommend him to try in the same way clairvoyance, spirit-rapping, Hollo-way's ointment cures, and the rest of these things? The promulgators of these trickeries could demand it on Dr. Chambers's principles; they all refer to their experimental proofs. But is there never to be an end of the trial accorded to each new quackery? Are we bound to waste all our days in experimenting the new remedy of every new or old quack that swears in its efficacy?

In the present state of science, are we not justified in believing all specific curers of cancers to be downright quacks: and that any one, for example, who boasts the possession of a specific for consumption, stands in a like position? Because these men impudently go into the market-places and shout out the wonderful powers of their wares in the ears of the populace, surely we men of medicine are not bound to listen to them, even though they back their promises and assertions with what Dr. Chambers calls a "Bible oath." Because a man, for example, can so delude himself as to swear that he believes serpent's excrement is something like a specific in consumption, are we bound to condescend to the repeating his experiments, or even to listen patiently to his barefaced nonsense? No; there must be some show of reason in the proposed remedy when medicine proceeds to its investigation; there is a degree of condescension to which medicine is not called upon to suffer, even to satisfy the cravings of an ignorant public.

But we have outrun our limits; and must conclude by again repeating that in our opinion Dr. Chambers has published a very good course of clinical lectures; that the instruction conveyed in them is good, practical, and scientific; and that we much wish his book had a better title, and that his introductory chapter had been omitted. We should then have had nothing to do but utter words of praise of it.

We are glad to find that, in this edition, Dr. Chambers has altered some phrases which we considered too popularly jocose in his first edition. We trust that his pruning-pen will not yet rest contented. We could still point to passages in which the metaphor is sadly overstrained and out of place. We also trust Dr. Chambers will, in his next edition, discard the word "allopath." To whom does he refer in using such a term? We know a vast number of medical men, but certainly, of the species *medici*, we know not a single one who can be included in his subspecies, "allopaths." Dr. Chambers even goes so far as to speak of "wise and foolish" allopaths. As homœopaths are not allopaths, we suppose allopaths must be, in Dr. Chambers's sense, medical men not homœopaths; and such medical men are by him bundled up with homœopaths, and treated as of equal worth. Thus, the allopathist (medical man) and homœopathist are made to run in couples. This is not right; for medicine is not homœopathy, however many its errors may be.

**PROFESSIONAL TESTIMONIAL.** A silver tea-service, a binocular microscope of one hundred guineas value, and a silver inkstand, have been presented by his friends and patients to Mr. Robinson, F.R.C.S., on the occasion of his leaving Edgware, where he has been engaged in practice during the past twenty years.

## DR. RADCLIFFE'S LECTURES

AT

### THE ROYAL COLLEGE OF PHYSICIANS.

In his eighth and last lecture, Dr. Radcliffe spoke of pain and paralysis, prefacing what he had to say with some remarks on "The State of Irritation." On this point, a physical explanation was offered, which was in accordance with the physiological view of muscular action and sensation propounded in the first four lectures. The "state of irritation" was seen to have nothing to do with an inflammatory or congestive condition, except that it may, in some instances, give rise to such a condition as a secondary result.

Speaking of pain, and sensations analogous to pain, Dr. Radcliffe adduced evidence to show that their physiological and pathological conditions were, in every particular, analogous to the physiological and pathological conditions of the various forms of convulsion, spasm, or tremor. The physiological evidence adduced was very curious; the facts themselves being at once novel and striking. The pathological evidence amounted to this: that pain, and the sensation analogous to pain, were, as a rule, associated with a state of deficient vigour in the circulation, respiration, and innervation, and not with the contrary state. It was argued, for example, that pain, as a rule, is the precursor of inflammation, and not the attendant; that pain gives place to tenderness where inflammation is developed, except in those cases in which the inflammation is in a place where the due amount of swelling cannot take place, and where, consequently, this resisted swelling becomes a very intelligible cause of pain.

The treatment suggested by these considerations is analogous to that recommended in the different forms of tremor, convulsion, and spasm; and with respect to this matter, the lecturer said that his own experience left him no room to doubt that this mode of treatment led to more satisfactory results than that which is dictated by the notion that pain, and the sensation analogous to pain are the signs of exalted vital activity in nerve-tissue.

With respect to paralysis, the lecturer said much upon the current views which regard cramps and other disorders of muscular motion, and pain and the analogous disorders of sensation, as conclusive evidence that the paralyzing lesion is of an inflammatory or congestive character. Dr. Radcliffe held that the very opposite view is much nearer the truth; and he supported his opinions with a great amount of evidence. As to the use of strychnine and belladonna in the treatment of paralysis, the conclusion came to was that the cases in which these drugs are likely to be useful or harmful are not those in which they are spoken of on high authority as useful or harmful, but rather the reverse.

The lecturer maintained that symptoms of irritation are in no sense a reason for the adoption of remedies which will diminish a hyperemic condition of some part of some nervous centre, and in that way lower functional activity, but rather the reverse; and he asserted broadly that he had good reason for believing that this view would bear the test of actual practice.

# British Medical Journal.

SATURDAY, JANUARY 3RD, 1863.

## RETROSPECT AND PROSPECT.

THE author of the Pythagorean *Aurea Carmina* enjoined his disciples to question themselves individually each night, as to their transgressions, their actions, and their omissions.

“Μήδ' ὕπνον μαλακοῖσιν ἐπ' ὕμμασι προσδέσασθε,  
Πρὶν τῶν ἡμερῶν ἔργων τρὶς ἑκάστον ἐπελθεῖν·  
Πῇ παρέβην; τί δ' ἔρεξα; τί μοι δέον οὐκ ἐτελέσθη;”

The duty here insisted on is incumbent on bodies of men acting in common no less than on individuals; and therefore we, writing at the close of the year one thousand eight hundred and sixty-two, purpose to glance back at some of the events and topics of the past year, in which the medical profession is specially interested.

Various events which have from time to time occurred, and practices which are upheld, within the profession, or in its relations to the public, have during the year been recorded and commented on in this JOURNAL. Let us recal to attention the principal of these.

The faulty state of our system of giving and taking medical evidence in courts of law has been several times brought under notice. It is felt strongly by ourselves, as well as by many at least of our fellow-associates, that the present plan, by which the medical witnesses are made to assume the position of advocates on each side, is neither conducive to the ends of justice nor creditable to our profession. The remedy for this, as has been several times pointed out, is the appointment of experts on the part of the Crown to examine into the medical points of any case brought forward—whether of poisoning or of lunacy—so as to avoid that discreditable display of conflicting evidence which only confirms the public in their notions of the fallacy and uncertainty of medical science.

Another matter connected with the position of the medical profession in law courts, on which we have found it necessary sometimes to comment strongly, is the apparent readiness with which some members of the profession throw in the weight of their testimony towards passing a harsh judgment on the errors or omissions of a professional brother, who may, by an unfortunate event in his practice, have subjected himself to legal process on the part of those who—naturally enough, it may be admitted—imagine that his conduct requires investigation and perhaps punishment. The remarks which we have made on this subject have, we have been glad to find, already produced good effect; and we trust

that what has been said will lead to a more extensive and practical recognition of the obligations which the great principle of charity to our neighbour and brother imposes on us all.

While we have been obliged to lament the frequent manifestations of a want of true charity, and to stimulate the exercise of this virtue among ourselves, it has no less been our duty to animadvert on the evils arising from the misplaced or pseudo-charity which prevails in our public institutions for the relief of sickness; and to show how unjust is the custom under which the medical attendants on our hospitals, infirmaries, and dispensaries, generally receive no remuneration for their labours—bestowed often on persons who have no claim for gratuitous relief. The subject has engaged the attention of several active members of our Association; and it is to be hoped that means will be found to arrest the spread and diminish the prevalence of a so-called system of charity, which, being compulsory, is in fact no charity at all.

Closely connected with the subject just mentioned, is that of the medical relief of the sick poor. To remedy the evils and inconsistencies of the system under which this relief is at present afforded, our excellent and zealous associate Mr. Griffin is, we believe, still labouring. The matter has also been brought under the notice of our Committee of Council, who, in April last, addressed to the Poor-law Board a memorial, setting forth the amendments which they considered advisable. We wish we could congratulate the Poor-law surgeons on the prospect of a speedy and satisfactory settlement of this difficult question; but we would urge on them, and on our associates generally, to study the matter in an aspect which shall be at once just and liberal, and not to despair of gaining by perseverance that redress for which the faults and anomalies of their position call.

Another matter, having a bearing on the public position of the medical profession, is the conduct of its members towards the practitioners of the so-called homœopathic system. On two or three occasions during the past year, attention has been called to alleged consultations of medical men with globulists. We believe, however, that the previous condemnation of the practice in this JOURNAL, supported as it was by the general professional sentiment, has had the effect of showing that the deliberate contact and consultation of truth with error and falsehood cannot be tolerated among us. A remarkable instance of the recognition of this principle was shown some months ago in a case, in which a leading physician in one of our large manufacturing towns actually threatened legal proceedings against a fellow-practitioner for reporting that he—the said physician—had met a homœopath in consultation.

Another matter at once of professional and public

interest, which has come under notice during the past year, is the qualification of coroners. The death of Mr. Wakley having left a vacancy in the coronership of West Middlesex, and the district having been thereon divided into two parts, our associate Dr. Lankester offered himself as a candidate for the central division. Feeling—independently of the high qualifications of Dr. Lankester for the duties of the office—how specially the medical man rather than the lawyer was fitted for the office of coroner, we did not hesitate to support Dr. Lankester's claims to the best of our ability. The result of the combined and energetic action of the profession in London on his behalf was his election to the office—an encouraging instance of the carrying out of an important principle as to the qualifications of the coroner, and of the success which may be expected from a display of well-organised energy.

From these matters, in which the relations of the medical profession to the public are most prominent, let us turn to a few of these in which this double aspect is less distinct, and which are, at first sight, more strictly professional.

The Medical Council met in May last; and, among the principal matters which it took into consideration, were the Medical Act and the new *Pharmacopœia*. The Medical Act, while it has not been without some good result, has not been so effective to fulfil all its objects as is desirable; and the Council have, therefore, taken in hand the preparation of a draft bill, which will probably be brought forward for consideration at their meeting next year. The great ultimate causes of difficulty and delay in the preparation of a national *Pharmacopœia* have been the question of the abrogation of the existing rights of the three Colleges of Physicians to publish their own *Pharmacopœias*, and that of the adjustment of weights and measures. The former question has, we believe, been settled easily; the latter has been more difficult to manage. After much discussion of the subject, both in the Council and without, the matter has been for the present arranged by the retention of the old grain (an alteration of which was at first proposed) together with the avoirdupois ounce; and the abolition of the apothecaries' scruple and drachm. The proposed alteration in our medicinal weights has caused attention to be directed to the decimal or metrical system in use in most continental countries; and the advantages of this system, and the importance of at least introducing it collaterally with our ordinary system, have been ably insisted on by several correspondents who have carefully studied the subject.

The regulations of our licensing bodies have undergone considerable modifications since the Medical Council commenced action. These regulations, thus altered, were given in full in the JOURNAL of Sept.

27th and Oct. 4th; and the principal changes which they had undergone were pointed out. At the close of the year, the ancient University of St. Andrew's has been holding the last of its examinations under the old *régime*; the ordinance of the Scottish University Commissioners demanding residence from future candidates. We learn that above two hundred and fifty practitioners have sought to avail themselves of the opportunity now for the last time offered them, without restraint as to numbers, of being admitted to examination for their degree on the mere production of a diploma or license from some other board.

While most of the examining boards have fallen in with the desires of the Medical Council, the College of Surgeons of England has called on itself considerable obloquy by not strictly complying with the wish of the Medical Council that the testing of general education should always precede the commencement of professional education. In the matter of its self-government, the College, on the occasion of election of members of its Council, departed from its ordinary course so far as to elect a provincial surgeon—Mr. Paget of Leicester. It has, however, still adhered to certain objectionable customs in regard to the election of the president and of the examiners, which we pointed out and commented on at the proper time.

The Royal College of Physicians of London has fully organised its scheme of giving a general license to practise medicine, completing that organisation a few weeks ago, by the appointment of an examiner in surgery in the person of Mr. Erichsen.

Among those interested in our great London hospitals, the leading topic of discussion has been that arising out of the removal of St. Thomas's Hospital, necessitated by the purchase of its site for railway purposes. Arguments for and against the rebuilding of the hospital in a rural locality have been brought forward; and, as the affair at present stands, the hospital is temporarily located in what was once known as the Surrey Gardens, with the prospect of being rebuilt in a more suburban situation than that which it formerly occupied, but nevertheless very accessible to patients.

In the medical staffs of hospitals, changes have, as usual, occurred. Among them we may refer to the retirement of Dr. George Budd from King's College Hospital, and of Dr. Bence Jones from St. George's, as illustrations of the recognition of a principle which we have advocated. We could wish, however, that the principle of retirement after holding office during a certain number of years were more generally acted on.

Among the deaths which have occurred in the medical profession during the past year, that of Sir Benjamin Brodie has called forth the most widely spread and unanimous expressions of regret both

within and without the profession. A sketch of the professional life, character, and writings of this distinguished surgeon was published in the *JOURNAL* for November 15th. During the year, also, there has departed a man noted in the annals of medical politics—Mr. Wakley. His death gave occasion to a contest for the succession to his office of coroner, to which we have already alluded as resulting in a manner highly satisfactory to the medical profession.

In scientific matters, there has been a display of energy in the direction of inquiring into some of the unsettled points of medical science. The Royal Medical and Chirurgical Society has adopted the plan of appointing committees to inquire into certain subjects. A report on Suspended Animation was presented during the last session, and was published in abstract in this *JOURNAL* for July 5; and a committee has been formed by the same society for the purpose of investigating the action and uses of chloroform. Our Association also, at its annual meeting last August, instituted a series of inquiries into the action of remedies, which, it is trusted, will bring forth results of great practical benefit.

The progress of several special subjects of scientific interest has also been noticed in our pages. The investigations of M. Marcy on the pulse, the splendid discovery of the spectrum analysis by Bunsen and Kirchhoff, and the researches of M. Pasteur on the question of spontaneous generation, are among the matters which have been laid before our readers. The modern doctrines regarding syphilis, also, have been ably expounded by Mr. Henry Lee, as well as by Mr. Berkeley Hill, who has furnished an epitome of the views of the leading continental syphilographers.

In the surgical world, ovariotomy is in the ascendant. This operation, once regarded as formidable and hence rare, has been performed many times, with such results as appear to justify a position for it among recognised surgical proceedings. On two recent occasions, it has formed the subject of debate in the Royal Medical and Chirurgical Society; and during the year, the success with which it has been performed here has caused our French *confrères* to direct their attention to it, and to perform it in several instances, with various results.

Having thus taken a rapid review of some of the leading medical topics of the past year, we would now say a few words on the position of the Association and of its *JOURNAL*.

The Association, we believe, was never in a more healthy state than at present. We learn that the number of resignations, which ordinarily take place at the end of each year, is on this occasion much more than compensated by the accession of new members. Our financial position, too, is very satisfactory. The London meeting continues to be

remembered with the highest satisfaction; and the proceedings on that occasion, in regard to an inquiry into the action of medicines, have, it is believed, done much to uphold the reputation of the Association as a means of promoting medical science. The Association also, at the same meeting, adopted a series of resolutions respecting an improved system of registration of births and deaths in Ireland; and negotiations on this subject are still proceeding with the Secretary and Council of the Social Science Association.

The various Branches have also manifested their usual activity, and in some cases have shown a desire to increase their utility. The Lancashire and Cheshire Branch, especially, has instituted meetings for the reading of papers, and has organised a scheme for the yearly delivery of short courses of lectures on topics of medical science.

In the *JOURNAL* we have, as heretofore, endeavoured to collect the most important professional information current. Our own share in this, and of the manner in which we have striven to uphold just and right principles, we must leave to the judgment of others. But we must express our hearty and sincere thanks to those who have so liberally aided us by their contributions. It would be impossible to particularise all to whom we are thus indebted; but the scientific reputation of a medical periodical cannot be small when it numbers among its contributors such men as Dr. Acland, Dr. Beale, Dr. Hughes Bennett, Mr. W. Bowman, Dr. Burrows, Dr. T. K. Chambers, Mr. Clendon, Dr. Copeman of Norwich, Dr. R. P. Cotton, Mr. De Morgan, Mr. R. Dunn, Dr. Fleming of Birmingham, Dr. Goodwin of Bury St. Edmunds, Mr. Greaves of Manchester, Dr. Headlam Greenhow, Mr. E. Hart, Dr. Harley, Mr. P. Hewett, Dr. Graily Hewitt, Mr. T. Hunt, Mr. J. Hutchinson, Dr. Handfield Jones, Dr. Latham, Mr. J. Z. Laurence, Mr. Henry Lee, Mr. Paget of London, Mr. Paget of Leicester, Mr. Prichard of Bristol, Dr. Ranking of Norwich, Mr. Rigden of Canterbury, Dr. Roberts of Manchester, Dr. Routh, Dr. Russell of Birmingham, Dr. Hyde Salter, Dr. Shann of York, Dr. Sharpey, Dr. Skinner of Liverpool, Mr. Square of Plymouth, Mr. Steele of Liverpool, Dr. Swayne of Bristol, Mr. Syme of Edinburgh, Mr. Toynbee, Mr. Haynes Walton, Dr. Waters of Liverpool, Mr. Thos. Windsor of Manchester, Mr. J. C. Wordsworth, etc. All of these, with many others whose names the limits of our space alone prevent us from mentioning, have contributed from the stores of their experience and study to the enrichment of the *JOURNAL*.

For the future year, our prospects are equally encouraging. Among those on whom we can already depend for contributions in the form of clinical lectures, etc., are Dr. L. Beale, Mr. Brodhurst, Dr. W. Budd, Dr. Burrows, Mr. Curling, Mr. Prescott Hewett, Dr. George Johnson, Dr. Latham, Mr. Henry

Lee, Mr. James Paget, Mr. Solomon of Birmingham, Mr. Syme of Edinburgh, Mr. Haynes Walton, Mr. Spencer Wells, and Mr. Erasmus Wilson. In addition to the valuable communications which there is every reason to expect from these gentlemen, supplies will no doubt, as heretofore, come in abundance, with little or no solicitation from us.

Altogether, there is every reason to expect that, when the time for our annual gathering shall again come round, the Association will be found to have become more stable, more vigorous, and more useful, than even it has already been. *Floureat semper.*

### A VILLAGE HOSPITAL.

We are glad to find that the modest village hospital at Cranley flourishes. The object of this hospital is stated in the report before us—its third annual report.

“The institution of the village hospital resulted from the absolute necessity of providing better accommodation for the poor, in cases of sickness or accident, than that afforded by their own homes. The distance of the London hospitals prevents them from being of much use to the poor in country districts; and the change also to the atmosphere of London is oftentimes in itself prejudicial to the health of country patients.”

The hospital contains six beds; and, during the past year, thirty cases have been treated in it. The advantages gained to the labouring poor by such establishments—placed at his very door—are manifest enough. Patients suffering from accidents and acute diseases receive instant relief. There is another incidental good which also arises out of them; and that is, that they afford the village surgeon an opportunity of performing operations and studying diseases, such as he could not otherwise possess. They appear also to be capable of very economical management.

One or two points in the Report are worthy of especial attention. The patients seem all of them to have been of the labouring class; and yet we find that about one-fourth of the expenditure of the little hospital was paid for by them, through a system of weekly payments. Of £175 expended, £45 were paid by patients. Could any more striking proof be given of the abuses practised in our metropolitan hospitals, after the manner to which we have so often called attention?

One other remarkable fact we see in the balance-sheet: £6 are charged for surgical instruments, but not a single penny for drugs!

We cannot, however, help asking one question of Mr. Napper, the medical superintendent. Why should he be called upon to give his gratuitous services to this village hospital? We have no doubt that he has subscribed his money to it. On what principle of equity or ethics, then, is he to be called upon to give his time, talents, and services into the bargain? Surely it is for the benefit of the commu-

nity in which he dwells, and not for his own, that this labour of his is given. Why, then, should not the community pay for the benefit? Who will say that, in such case, the community at large is not infinitely better able to bear the burthen of the charge than the individual doctor?

### THE WEEK.

THE *Tartuffe* of the medical press closes its journalistic year with a reiteration of the shameless calumny which, for purely commercial purposes, he was pleased to invent and bring against the British Medical Association in August last. He now again, with the unction of his unflinching tribe, takes credit to himself for having made public property of the proceedings of the Association. We are not going again to relate *Tartuffe's* tricks on the occasion referred to; they stand recorded on our pages. But as we then told that gentleman, we tell him again, he may rest assured his mouthpiece shall not repeat the invention without receiving the denial to it. He shall not, so far as we are concerned, have the benefit of the credit which his assertions might otherwise obtain simply through unblushing repetition of them, after their utter want of foundation has been again and again demonstrated. Let it then be known that the *Lancet*, whose reporters had the freest admissions to all the meetings of the Association, and who actually reported and printed the proceedings of the Association, and who was offered by this JOURNAL slips of all the papers read at the meeting, has the courage again, after the cool reflection of many months, to print the following lines, when pluming himself on what he has done for the profession.

“The British Medical Association has held its annual meeting. We had occasion to give a practical rebuke to the ridiculous arrogance of a party which assumed an exclusive right of property in the mental labours of those eminent men who contributed addresses and papers to the Society. The British Medical Association, like every other body professing scientific and public objects, will henceforth recognise the necessity of acting under the eye of the press. It will not again commit the absurd mistake of supposing that these objects can be attained by confining a knowledge of its labours to that section of its own members who alone read the record of their own doings in the little publication devoted to that purpose.” If this be the best feather *Tartuffe* can find to adorn himself with, our readers may take their measure of his plumage.

THE *American Medical Times* gives the following doleful account of the state of the drug market in New York.

“The effect of the rise of prices is very sensibly felt by druggists. In many instances, the prices of the most common drugs have increased fifty per cent. The druggist, however, can scarcely add to his charges in the retail of drugs without receiving censure. The retail drug business must, therefore, suffer severely. But the retail druggist who does a large business in prescrip-

tions has a remedy in the enormous profit on prescriptions. Physicians should be informed of this increase in the price of drugs; and as far as possible, when prescribing for the poor, select those articles least expensive, and yet capable of accomplishing the desired result."

WE understand that an action has been brought against Dr. Philbrick by the man Bull, to recover damages for the loss of his wife. We have already freely expressed our opinion concerning the evidence of the medical men who gave evidence at the coroner's inquest into the cause of the woman's death. We have shown that the main part of that evidence which was brought to bear against Dr. Philbrick was mere matter of opinion, and that the conclusions formed thereon were not fairly warranted either by practical experience or pathological considerations. The result of all this is, that Dr. Philbrick is now, and we need hardly add, in our opinion most unjustly, exposed to the serious injury of a law-suit, of a heads-I-win-tails-you-lose character. It is perfectly clear that, in a case of this kind, Dr. Philbrick must be a loser even if he win the day. We feel bound to say that we think Dr. Philbrick in this matter deserves the sympathy and support of his professional brethren; for, had his professional brethren stood by instead of condemning him, this action never could have been brought against him. We are satisfied that every one who, unbiased, investigates the history of the coroner's inquest out of which the action arises, will agree with the view we have here given of it.

FROM the following paragraph in the *American Medical Times*, we must conclude that the abominable trade of abortion-procuring is not uncommon in New York.

"Another case of induced abortion has come to light in this city by the death of the victim. Such an occurrence is suggestive of the thought that this is but an accidental exposure of a large and lucrative business. How many similar operations are performed, of which we know nothing, can only be surmised. There is no doubt, however, that the abortionists form a distinct craft among us, and are never in want of engagements. But they are rarely detected in their black art, and, when arrested, easily escape from the grasp of justice."

THE announcement made in the following paragraph will rather startle some of our readers, and, in fact, contains matter worthy of serious consideration.

"The Royal Dublin Society met on Saturday evening, to hear a lecture from Professor Gamgee on disease and mortality among cattle. When he had concluded, Mr. Ganley, salesmaster, made an extraordinary statement. He said that, unless some means were devised to give some compensation to the farmer for diseased cattle, it was impossible to prevent him from selling them, or the butcher from killing and selling them. Unless some society were formed to have diseased meat paid for, it would be killed and eaten. There was no use in mincing the matter, he said; every one of the salesmen sold diseased cattle. The farmer could not otherwise pay his rent. The disease is so prevalent, that he could not

live were he to submit his cattle to destruction. Professor Gamgee said he would have gone 1,500 miles to hear this confession; and he agreed with Mr. Ganley that some plan should be adopted for paying the farmer for diseased cattle."

We suppose that we are to conclude from the statement of Mr. Ganley, if it be true, that disease is so rife in cattle that the salesman cannot live unless he gets a price for the diseased meat which falls into his hands. The enormous quantity of what is called diseased meat which (notwithstanding the attempts made to suppress the illegal traffic) is daily thrust upon our markets, indicates that an immense number of our meat-supplying kine must be in a state of disease. The subject, in all its bearings, is one which requires a thorough investigation; it is still under a cloud. We should like to know, in the first place, what "diseased meat" is; to have, in fact, a fair and practical definition of the term. Then, again, it would be well to know whether there are any diseases which, killing or tending to destroy the animal, do *not* render its flesh improper food for man; and what those diseases are, which, killing the animal, render the meat absolutely unfit for human food. Some food, we must suppose, is condemned as unfit food, not because it is the meat of diseased animals, but because it is far advanced in the stage of putrefaction. Again, above all, it would be highly satisfactory to have proofs, tangible and distinct, of the injury inflicted on humanity by the effects of this "unfit" food. At present, the whole subject seems to us to be in a highly unsatisfactory state. No doubt authorities do well, in the meantime, to err on the right side, and destroy all meat which may fairly be, *a priori*, considered as unfit for consumption. We cannot, however, help asking the question: Is the whole of the meat coming under the head of what we read of as "condemned" really and truly incapable of affording healthy nutriment, when properly operated upon by cooking and the digestive organs? Regular markets of horse-flesh are now established in Berlin; and it is hardly to be supposed that all the horses killed there can be without disease; yet, under the direction of the sanitary police of that city, the flesh is sold and eaten, and produces no ill effects, as far as we know, among the Prussian hippophagi.

WE much regret to note, from the following paragraph in the *American Medical Times*, that political animosities touching the American war are too readily excited even amongst our professional brethren.

"A London medical contemporary sneeringly remarks that American army surgeons who attempt to gain a livelihood by practice, after peace is restored, will quickly be reduced to the condition of the Lancashire operatives. This remark has significance only to an English mind, which cannot conceive of a country where the honest, frugal, and industrious citizen never knows want. And yet it ought to be apparent, even to Englishmen, that a country capable of carrying on the most gigantic war of

modern times, and at the same time of charitably relieving their starving countrymen by shiploads of food, cannot have a class of necessary paupers."

M. BURGGRÆVE has put into practice the theory of M. Polli—the employment of the sulphites in supposed cases of morbid ferments in the blood. The iatro-chemists, therefore, are still alive, notwithstanding Dr. Chambers's objections to them. M. Burggræve has communicated to the Belgian Academy of Medicine his experience in the use of these agents in cases of wounds, abscesses, and burns. The sulphite of magnesia is administered internally—one *gramme* (fifteen grains), in a glass of sugared water, four or six times a day. The sulphite of soda is employed externally, in lotions, etc. It produces, we are told, immediate local anæsthesia, which is particularly appreciated in burns, and allows of their being dressed and cauterised without pain. In sixty-five cases of wounds thus treated, the effects produced were immediate; the wounds improved, and became of a healthy colour; active granulation took place; the pus was scanty, inodorous, and tough as gluten. The application thus also acted as a disinfectant.

Hospitals of a certain class are, it would seem, leaving Paris for the country. L'Hospice des Incurables for men is shortly to be transferred to Ivry. L'Hospice des Ménages is also to be installed without the walls of Paris, at Issy, two *kilomètres* from the fortifications.

The Chair of Midwifery at Milan is at the present time being disputed (by *concours*) by Professors Grillenzoni of Ferrara (a deputy), Col-Bene of Modena, Paccianti of Naples, Madruzzo of Bologna, etc.!

*L'Union Médicale* takes the following French view the St. Thomas's Hospital question:—"A commission has been sent abroad to study hospital constructions; and the model adopted for its reconstruction is that of the Hospital of Vincennes. But the '*medical officers*' object: 'We must have a central hospital, or our school will lose its importance.' Thus two rival interests are called into play, and the general one is forgotten—viz., that of the patients and of humanity. Happily, however, the local press is there to defend the right, and will defend it."

On the 17th ult., the Nestor of German physiology, Professor Purkinje, kept his seventy-fifth birthday. A series of ovations were made to him, finished up by an evening torchlight procession.

At the French Academy of Medicine have been nominated for the ensuing year—as President, M. Larrey; as Vice-President, M. Grisolle; and as Secretary, M. Bécлар.

A pamphlet by Dr. Palasciano has been forwarded to us. Dr. Palasciano wrote it in consequence of finding that "the President had commu-

nicated to the Chamber of Deputies at Turin that the glory of having discovered the presence of a projectile in Garibaldi's foot belonged to an Italian—to the Deputy Cipriani, who, long before the advent of any foreign surgeons, had communicated the fact to him (the President) in a letter. [*Applause.*]" Dr. Palasciano now, by documents, shows this statement to be an error; and that the credit of the true diagnosis belongs to himself.

Dr. Heller, in *Wien. Med. Wochenschrift*, gives the following analysis of the urine of a lad six years old, who died of hydrophobia. The quantity operated on was about one pound. Its specific gravity was 1036, and very acid. The sediment consisted of uric acid, and was in greater abundance than Dr. Heller had ever met with. No urate of ammonia was found in the sediment. Of albumen, and of carbonate of ammonia, there was only a trace. It contained no sugar. The uropheine and uroxanthine were slightly increased. In the clear urine was also contained much uric acid. The urea was greatly increased, and was equal in quantity to what is met with in meningitis. The chlorides were very slightly diminished; the sulphates greatly increased. The earthy phosphates were much, and the alkaline phosphates slightly, increased.

M. Sédillot was made a Commander of the Order of St. Gregory the Great by the Pope, on the occasion of his medical inspection of the army of occupation at Rome.

A Berlin journal says:—"There are at this moment on our capital seven markets of horse-flesh. In the course of the first ten months of the present year 750 horses have been killed. No horse can be killed in these markets without a certificate from the veterinary surgeon of the police."

M. Dubois, in his eloge of Thénard, made the following comparison between chemistry and medicine before the Academy of Medicine:—"Chemistry had presented a marvellous spectacle to the world; very different from medicine, whose annals date from 3000 years ago, and which is yet still seeking a path in the midst of the uncertainties of its theories and the efforts of its experience." The Perpetual Secretary of an Academy of Medicine, writes a critic, speaking in the name of the Academy, before the Academy of Medicine, should have suppressed a parallel so unfavourable to medicine, particularly as it is not entirely true.

M. Delbrück has attempted to show that during sleep only a small amount of oxygenated air is required. His experiments, writes *L'Union Médicale*, are, however, valueless as demonstrative of the fact. They merely show that man and animals endeavour to preserve themselves from the effects of cold during the night—nothing more.

At Vienna, on the 13th ult., the fiftieth doctor-jubilee of Dr. F. Jäger was celebrated. He received

the good wishes of all the medical corporations; a new doctor's diploma was handed to him by the Doctorial College. Dr. Jüger's merits and works as an oculist are well known. He was, we read, the most faithful disciple of his master, Beer—the founder of the Austrian school of ophthalmology. His fame has spread through all Europe; and numerous orders adorn his breast.

### THE LATE DAVID EVANS, Esq., OF BELPER.

THE death of Mr. Evans of Belper, which took place on the 20th of November last, requires more than a passing notice.

For the last eight or ten years, owing to the infirmities of advanced age, he had retired from the active duties of his profession; but for many years previous to that time he was widely known as a most eminent operative and ophthalmic surgeon. His operations, in many cases, were marked by great ingenuity and boldness, almost always justified by success. He tied the carotid artery three times; twice successfully. As a lithotomist, and operator for hernia and cataract, he was particularly successful.

One striking excellence in Mr. Evans' professional character was the tenacious perseverance he displayed in applying the resources which great natural ability and careful observation constantly suggested; and he was thus, under Providence, the means of saving life in circumstances often considered hopeless, as illustrated by the following cases.

In a case of poisoning by laudanum, where the patient had taken an ounce and a half of laudanum and half a pint of gin, he successfully emptied the stomach, on December 6th, 1817, by means of a large syringe attached to an œsophageal tube on the principle of the stomach-pump, two years before that instrument was invented. The case was published in 1823 in the *Transactions of the Associated Apothecaries and Surgeon-Apothecaries of England and Wales*.

But the operation which caused a great sensation at that time, and extended his reputation even to foreign countries, was a case of aneurism of the arteria innominata, treated successfully by ligature of the common carotid on the distal side of the tumour. The case is recorded in the *Lancet* of November 1828, and in Wardrop's work on *Aneurism*. It may be interesting to the profession to know that the patient on whom this operation was performed is still living at Belper, in the enjoyment of good health, after a lapse of thirty-four years.

About the year 1833, Mr. Evans extirpated a cancerous uterus, in the case of Mrs. H., who survived the operation thirteen months. The uterus is at present in the museum of Queen's College, Birmingham.

The unwearied attention and kindness which Mr. Evans exercised in the discharge of his professional duties, his readiness at all times to lend his aid, and the confidence he inspired in those who sought it, will be testified to by all who knew him, in every station of life. Of his general character, it is more difficult to speak. Unobtrusive and retiring, and possessing an almost childlike simplicity, he was distinguished in an eminent degree by that charity which "thinketh no evil," while, at the same time, he was ever active in suggesting and promoting every good work. He is gone, full of years, to his rest, having entered his eighty-third year; but his memory will be long cherished, not only by the numerous family which he has left behind him, but by the many friends far and near who have long appreciated his worth.

### THE LATE ROBERT KNOX, M.D.

DR. ROBERT KNOX, well known to Edinburgh medical students of thirty or forty years ago, as a highly successful teacher of anatomy in that city, died of apoplexy at his residence in Hackney, on December 20, 1862. He was the son of Robert Knox, teacher of mathematics in the University of Edinburgh, and was born in that city on September 4, 1793. He claimed descent from that ancient and reputable Scottish family of Knox, of which John Knox, the energetic and turbulent Puritan reformer and iconoclast, was a member; and, we believe, was lineally descended from William, a brother of John. He was educated at the High School of Edinburgh, where he obtained the gold medal in 1810, and where his name still shines from a tablet on the wall, on which the names of the medallists are recorded. On leaving school, he studied medicine in the then illustrious Medical School of the University of Edinburgh, and, on taking his degree, entered the Army, and was appointed Staff-Assistant Surgeon, and attached to the 72nd Regiment. He soon after went to the Cape, and saw active service during the first Kaffir war in the years 1819-22. On his return he quitted the army on half-pay, and began to teach anatomy in Surgeon's Square, Edinburgh, as successor to Dr. Barclay. This was the meridian period of Dr. Knox's life. As an anatomist and teacher he was unrivalled: his lecture-rooms were crowded; and he is said to have taught between five and six thousand pupils during the time of his professorship, amongst whom the names of William Fergusson, John Hughes Bennett, Richard Owen, John Goodsir, the late Professor Reid, and the late Director-General Alexander, shine conspicuously. In 1845, he left Edinburgh and came to London, where his intellectual activity found vent in a variety of occupations. He gave lectures on Ethnology at the principal scientific institutes in the kingdom; he attached himself to the Royal Free Hospital in Gray's Inn Lane, and was pathologist to the Cancer Hospital. He also employed himself extensively in literature: and, in addition to a translation of Cloquet, which he had brought out some years before, and of Tiedemann on the Arteries, he translated Milne-Edwards' *Manual of Zoology* (of which a second edition was on the eve of publication at the time of his death); he wrote a new *Manual of Anatomy*, a particularly valuable book for the glimpses which it gave, short though they were, at something in anatomy above and beyond the dry empirical enumeration of surfaces and processes: a *Manual of Artistic Anatomy for the Use of Painters, Sculptors, and Amateurs*; a work entitled *Great Artists and Great Anatomists*; and, lastly, his immortal book on *Ethnology, or the Races of Men*. But besides these greater works, were many lesser memoirs scattered throughout the transactions of various natural history societies, of which a paper on the *Affinities of the Trout and Salmon* attracted much attention. Dr. Knox was early married, and had six children, of whom one only survives him. So far as outward person is concerned, nature was niggard in her gifts. He had lost an eye from small-pox in early childhood, and his features otherwise were not prepossessing; but no man can expect to be armed at all points; and if Dr. Knox was as ugly as Jack Wilkes, he was as great a favourite with the women. In gifts of speech he was unequalled. His voice bland and harmonious; his manner earnest and persuasive; his *fucundia*, or by whatever other name we may call that seemingly inexhaustible flow of the choicest and most apposite language, his clearness, his logical precision in speaking, and the enormous amount of information on all subjects connected with natural history and fine art, which flowed without effort from his lips—all conspired to make him justly a favourite with all who formed his acquaintance. (*Medical Times and Gazette*.)

## REGISTRATION OF BIRTHS AND DEATHS IN IRELAND.

*Extract from the Minutes of Council of the Social Science Association, November 20, 1862.*

In pursuance of notice, Mr. HASTINGS called attention to the following resolutions of the Council, passed on the 7th of December, 1861:—

"That a deputation be appointed to confer with the Irish Government, in promotion of an Act for the Registration of Births and Deaths in Ireland; and especially to press upon the Irish Government the expediency of proceeding in this matter on the principles adopted by the Council in their resolutions of June 7th, 1860."

"That the deputation also confer on the same subject with other members of the legislature."

Mr. HASTINGS read communications received from the President of the Royal College of Surgeons of Ireland and the Secretary of the British Medical Association, offering the cooperation of those bodies in the matter; and moved:—

"That the deputation be requested to act forthwith on the subject, to add to their number such members of the Association as may enable them to communicate directly with the Irish Government in Dublin, and to accept the offer of cooperation from the British Medical Association."

"That, in the event of the Irish Government declining to accede to the representations of the deputation, the Executive Committee be authorised to prepare a Bill embodying the principles approved by the Association, with a view to its introduction into Parliament."

The motion was seconded by Dr. GREENHOW, and carried.

*Extract from Minutes of a Meeting of Deputation, Nov. 29, 1862.*

It was resolved:

"That the Irish members of the deputation be requested to place themselves in communication with the Irish Government, for the purpose of ascertaining whether it is proposed to introduce a Bill for the Registration of Births and Deaths in Ireland during the next session of Parliament, and to urge upon the Government the great importance of framing a Bill upon the scheme suggested by this Association, and comprised in the following heads:—

"1. That there should be local scientific supervision of the registration of births and deaths.

"2. That the office of Superintendent-Registrar of Births and Deaths be held by persons well acquainted with the physical and biological sciences, versed in sanitary and vital statistics, and qualified to make medico-legal investigations.

"3. That all sickness attended in public institutions, or at the public expense, should be reported to and registered by the Superintendent-Registrar.

"4. That the cause or manner of death be in every instance authenticated by a certificate from a duly qualified medical practitioner, and that when such certificate be not delivered to the Registrar at the time of the registering the death, he shall report the circumstance to the Superintendent-Registrar, who shall forthwith make inquiry into the case.

"5. That the registration of births be compulsory; and that still-births after the sixth month of pregnancy, when not certified by a legally qualified medical practitioner, should be subject to the regulation stated in the last clause.

"6. That the Superintendent-Registrar should be paid by a stipend out of funds provided by Parliament, and be debarred from private medical practice."

## Association Intelligence.

### NOTICE REGARDING NEW MEMBERS.

By desire of the Committee of Council, the General Secretary requests that the Local Secretaries will be good enough to forward to him the names of all New Members who join the Association through the Branches; as otherwise the JOURNAL cannot be sent to them.

PHILIP H. WILLIAMS, M.D., *General Secretary.*

Worcester, November 10th, 1862.

### WEST SOMERSET BRANCH.

A *conversazione* meeting will be held at Clarke's Hotel, Taunton, on January 7th, 1863, at 7 P.M.

Gentlemen desirous of communicating papers or cases, are requested to send notice to the Honorary Secretary.

W. M. KELLY, M.D., *Hon. Sec.*

## Reports of Societies.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, DECEMBER 9TH, 1862.

B. G. BABINGTON, M.D., F.R.S., President, in the Chair.

CASE OF A WOMAN WITH THREE HANDS; ILLUSTRATED BY ANALOGOUS MALFORMATIONS IN THE LOWER ANIMALS.

BY J. JARDINE MURRAY, ESQ., BRIGHTON.

[Communicated by CHARLES H. MOORE, *Hon. Sec.*]

THE case, which was illustrated by large photographs, derived additional interest from the circumstance that no similar malformation had been met with in the human species.

The patient, aged 38, was a well-developed, healthy, active, and intelligent woman. She was married, and had had one child, in all respects normal. None of her relations had been or was the subject of malformation. The left upper extremity was the only abnormal part. The limb was muscular, the shoulder natural, and the external condyloid ridge of the humerus very prominent. Flexion of the elbow-joint was imperfect. The supernumerary hand was somewhat smaller than that which it so strangely accompanied. The thumbs were rudimentary. In working as a charwoman, the patient leaned on the back of the flexed carpus. The double-hand could grasp firmly, though the maximum of power was not equal to that of the woman's right hand. Sensation was equally acute in all three hands.

Explanation of the case was sought for by referring to comparative teratology; and drawings of two cases of double fore-foot in the pig were exhibited, in both of which the duplicity, as in the double-hand, began at the carpus. Drawings and preparations of somewhat similar malformations in birds were also shown.

UNIVERSITY OF EDINBURGH. A poll for the election of Honorary President of the Associated Societies of Edinburgh University took place on Tuesday fortnight. The votes recorded were as follows:—For the Lord Advocate, M.P., 115; for the very Rev. Dean Ramsay, 100; for the Rev. Charles Kingsley, 81. The Lord Advocate, being highest on the poll, was elected. The office has been held successively by Sir E. B. Lytton, Sir John McNeill, and Professor Aytoun.

## Correspondence.

DR. TWEEDIE AND DR. MURCHISON.

LETTER FROM CHARLES MURCHISON, M.D.

SIR,—The letter from Dr. Tweedie in your last number, together with your comments thereon founded upon his statements, demand a reply from me. I have at the same time to express surprise, that you should have passed a judgment on the case, upon the assertions of one side only, notwithstanding the unbiassed opinion arrived at by your reviewer. I have important corrections to make on those assertions, which must lead your readers to a different conclusion.

1. It is not the fact that I drew up my statistical tables, either at the suggestion, or on the plan, or under the directions of Dr. Tweedie, nor that I undertook the work for his lectures. I had begun the analysis of the data contained in the records of the Fever Hospital, as an independent research, *months* before I heard or knew of Dr. Tweedie's intended lectures. Dr. Tweedie may know when he formed his decision; but he is not, and cannot be, a competent or credible witness as to when I formed my design, and began the execution of it. Dr. Tweedie asked me to ascertain for him the sexes and mean ages of one hundred cases of typhus and typhoid fever; and on my reminding him, that I was already engaged in a much more extended inquiry, he expressed a wish to avail himself of the results for his lectures. The internal evidence respectively of his work and mine will show that I had a higher aim, than that of being a mechanical drudge to Dr. Tweedie. The conception, plan and execution of my tables were wholly and solely my own.

2. It is not the fact that Dr. Tweedie was in possession of my tables, "at least a year before his lectures were delivered," for the tables were brought down to December 31st, 1857; they were not even finished until February 1858, while Dr. Tweedie's first lecture, in which they were used, was given on March 12th, 1858.

3. It is not the fact that Dr. Tweedie was not informed of my intended paper to the Royal Medical and Chirurgical Society, until *after* he had received my tables. When they were handed to him, he was distinctly aware that they were only lent to him for his lectures, and that they were prepared to accompany that paper, which bears the record of having been received by the Society on March 30th, and read on April 27th, 1858. (*Med-Chir. Trans.*, vol. xli, pp. 219-306.)

4. The appended notes, to which Dr. Tweedie refers, were brief memoranda, not exceeding two or three pages, explanatory of the object of the tables; while the paper under reference extended to eighty-eight pages of letter-press. Dr. Tweedie never saw the manuscript of this paper, which alone contains the passages, where his language and mine is identical. I had the permission of the Hospital Committee, as well as the sanction of *both* the physicians, Dr. Tweedie and Dr. Southwood Smith, to make use of the records of the hospital for fever statistics; and I can prove by the testimony of a distinguished Fellow of the College of Physicians, that he had perused the complete manuscript of my essay *before* the delivery of Dr. Tweedie's first lecture, at which he was present.

5. Dr. Tweedie, in his published *Lectures* (page 198), actually cites, not MS. memoranda, but my *printed essay*, as the source whence he derived the information which, according to your reviewer, he has made use of in such a manner, as to lead to a wrong impression as to the shares contributed by him and me respectively. He refers to it repeatedly, and at one place observes: "I am bound to acknowledge, that for the statistical facts, I am indebted

to the recently published paper of my colleague, Dr. Murchison, who, availing himself of the ample opportunities the Fever Hospital afforded, has produced a most valuable monograph on the mortality of the different forms of fever, and on the causes, which apparently influence their prevalence. (*Med-Chir. Trans.*, vol. xli.)" \*

6. It is necessary to bear in mind the distinction between the crude materials existing in the Registers of the Fever Hospital, and the conclusions which by analysis may be deduced from them. No complaint has been made of Dr. Tweedie's having used my tables; he had my permission to use them. But it is otherwise when he adopts my reasonings and views, in the *ipsissima verba* of my printed essay, in such a manner as to lead his readers to think, that my remarks are his own observations upon the facts collected by me. The very manner in which he introduces my name at certain places, is calculated to make the reader believe, that some of my remarks are his qualifications of views expressed by me. A comparison of page 202 of Dr. Tweedie's lectures with page 290 of my essay in the *Med-Chir. Trans.*, is sufficient to show, that the notice in my preface was fully called for. It is unnecessary for me to enter into the details of the manner in which Dr. Tweedie has appropriated my writings, as this has been done by your reviewer, who, as you say, "took the case as it stood before him in the works of the two authors," unbiassed by either party, and whose statement of facts is in no way invalidated by your remarks. (See also *Med. Times and Gazette* of January 3rd, 1863.)

7. I have not been indebted to Dr. Tweedie for any facts obtained by him by correspondence with leading provincial physicians, as to the recent prevalence of fever. The leading physicians of Great Britain and Ireland well know how often I have troubled them, during the last six years, for information on this point; and, indeed, Dr. Tweedie, in his *Lectures* (p. 200), admits that I had made a valuable addition to the statistics of the London Fever Hospital, by collecting those of provincial and other hospitals.

8. With reference to Dr. Tweedie's statement, that he had mentioned to me some months ago his intention of republishing his lectures, I beg to remind Dr. Tweedie that *it was I* who, in August, interrogated him whether the report to that effect was correct, adding that if such was the case, I would require of him to alter the expression made use of in his lectures in the *Lancet*, that he had suggested my inquiries to me (*vide Lancet* 1860, i. 3); and that if he did not do so, I should be under the necessity of taking notice of the matter as an unwarranted assertion. Dr. Tweedie at once consented to omit the expression objected to, and did so; yet he now reiterates that it is strictly accurate. This I again emphatically deny. It is an erroneous, and apparently ineradicable, impression on Dr. Tweedie's mind, that what was lent to him for his use, was originated by him.

9. I have no recollection of Dr. Tweedie asking me if I desired him to make any other alterations; but even if he did so, I could not have stated the grounds of my present complaint. It was not until some weeks after the occasion alluded to, on finding how my words had been attributed to Dr. Tweedie, in one of the Cork Fever Hospital Reports, that I was induced for the first time to read Dr. Tweedie's lectures, so as to discover the free use which he had made of my writings without acknowledgment.

10. The preceding paragraphs have reference solely to my essay in the *Med-Chir. Trans.*; and I beg to call the attention of your readers to the circumstance, that my preface contains no other allusion to Dr. Tweedie in

\* The first half of Dr. Tweedie's lectures were delivered in March 1858, and the remainder in 1859; but none of them were published until 1860. My essay was published in December 1858.

connection with that paper than the following:—"Most of the tables contained in the essay referred to, together with my remarks upon them, have been adopted by Dr. Tweedie in his *Lumleian Lectures*, published in the *Lancet* for 1860."

11. The only other reference to Dr. Tweedie in my preface is as follows:—"Dr. Tweedie, being about to republish his lectures, I feel it due to myself further to state, that most of his facts and reasonings bearing on the question of 'change of type' of continued fevers will be found in a paper published by me in the *Edinburgh Medical Journal* for August 1858. As Dr. Tweedie omits to mention my paper, I think it necessary to allude to the circumstance, lest it might appear that I had now borrowed some of my remarks from his lectures without acknowledgment." The paper here referred to had no connection with that published in the *Med.-Chir. Trans.*; and but few of the facts and reasonings contained in it were derived from the statistics of the London Fever Hospital. Dr. Tweedie's lecture, treating on the subject in question, was not delivered before 1859;\* and in the meantime, he received from me two copies of my paper, having mislaid one of them. I never had any conversation with Dr. Tweedie on the question of change of type in fever, except in reference to the published paper which I had given to him. Concerning this paper, your reviewer, who was guided solely by the documents before him, observes:—"The facts collected by him (Dr. Murchison), and a great part of the arguments derived from them (as given in a paper published in the *Edinburgh Monthly Journal* for August 1858), have been transferred by Dr. Tweedie to his lectures (pp. 214-217) without the least acknowledgment, and even in such a way as to lead to the impression that they are Dr. Tweedie's own." If this be the opinion of an unbiassed reader, it is obvious that the explanation in my preface was necessary for my own protection.

12. I have further to observe, in reference to the indignant tone of Dr. Tweedie's remarks, that although five weeks have elapsed since the publication of my work, Dr. Tweedie only now comes forward to express them publicly. On December 2nd, he deputed a distinguished Fellow of the College of Physicians to see me in reference to the statements in my Preface concerning himself. That gentleman, after carefully investigating the whole of the documentary evidence, and hearing what Dr. Tweedie and I had to state, informed Dr. Tweedie by letter that, in his opinion, I should have been open to serious misconstruction if I had remained silent, and that the remarks in my Preface were justified by the facts of the case. Indeed, the referee's letter was so similar in its terms to those employed by your reviewer, that when the review appeared, the referee thought it necessary to communicate with Dr. Tweedie to disown its authorship. I invite Dr. Tweedie to publish his own referee's letter.

Lastly, I have to observe that the remarks in my Preface, which have led to this discussion, were made, not aggressively, but in self-defence, to protect myself from the imputation of having copied from Dr. Tweedie without acknowledgment. Entire sentences in Dr. Tweedie's published Lectures are couched in the identical words employed in my previously published essays; so that I was under the necessity of giving some explanation. If seniority in standing is to justify the appropriation of the labours of a junior, a new canon will have been introduced into the code of professional ethics. And, because I have acted in self-defence, Dr. Tweedie has so far forgotten himself as to attribute to me "the most unworthy motives". I need hardly add that I repudiate the imputation. Such language is unusual on the part of one Fellow of the College of Physicians towards another; while the imputation of motives in all

such discussions is commonly regarded as the sign of a weak cause, or of a failing argument. Moreover, this remark has been elicited from Dr. Tweedie, not by my Preface, which he allowed to pass for weeks without any public notice, but by the review in your pages, with which I had no connection whatever.

I am, etc., CHARLES MURCHISON.

79, Wimpole Street, W., December 29th, 1862.

[Dr. Murchison is under a misconception in supposing that, in the remarks made in our last number, we passed any judgment upon the case. What we did was this: we willingly accepted Dr. Tweedie's statement as explaining away the charge of plagiarism brought forward in the review. The charge of plagiarism, it must be remembered, was not made by Dr. Murchison himself in the Preface to his work on *Fevers*; but, as we said last week, the statement there made, after comparing the writings of the two authors, led our reviewer to make use of the expression in question. EDITOR.]

## VACCINATION.

LETTER FROM THOMAS S. FLETCHER, ESQ.

SIR,—I understand that it is the intention of government to bring in a Bill in the next session of Parliament materially to alter the present Vaccination Acts; or to repeal them, and introduce another *de novo*. If this be the case, it is important to know the opinion of the Government Inspectors. Dr. Stevens was here lately to inquire into the working of the Vaccination Acts in this union. He says: "The public vaccinators in this union are far too numerous;" and "it appears necessary that vaccination should be carried on only at certain more or less distant periods, quarterly or half-yearly, according to the population of the station, and be persevered in so long as there were any applicants. Each periodic vaccination should be preluded by public notices posted and distributed in the neighbourhood of the station. Should it appear the public neglect to attend, an example should be made by legal proceeding; and a printed statement of the successful result of any such proceedings, if appended to succeeding public notices, would materially aid in increasing the attendance of the public at the stations."

Experience convinces me universal vaccination can never be carried out by the above plan. The great mass of the public will not be vaccinated, when, where, and by whom, the law says they shall; and the more you try by law to compel them, the less likely you are to succeed.

Why not try a simple registration measure; and if persons have a conscientious objection, let them (under certain regulations requisite for public safety) retain their opinions.

I would propose that parents not having a child vaccinated, and on the eighth day taken for inspection, and the vaccination registered, as directed (Schedule A.), should be liable to a fine not exceeding twenty shillings; and if not paid, an imprisonment not exceeding seven days. Should they afterwards continue to neglect, they will again be liable to the same proceedings.

(1) Should the child be incapable of taking the vaccine disease; or (2) should it not be in a fit state to be vaccinated; or (3) should they be unable to procure satisfactory lymph; or (4) should there be delay from the child having been (as it is commonly called) "vaccinated", and it has not taken effect; or (5) should they have a conscientious objection to vaccination: if they fill up the following exemption-paper, and register it, where and when the vaccination was to have been registered, it will prevent proceedings being taken.

The first reason for exemption requires a medical

\* See previous note.

certificate; and, being permanent, need not be renewed. The others are temporary, and must be renewed in June and December in each year. Own residence and full particulars of the then residence of the child, must always be given.

I would also propose that the Registrars, at the end of a quarter, when they apply for their fees for registering births, should also receive from the same source the medical fees for gratuitous vaccination. One uniform fee of, say 2s. 6d., for each certificate they have received (Schedule A) of vaccination having been performed gratuitously; and pay the fees over to the medical man who certified to the vaccination. If the latter live out of the district, payment might be made by post-office order, unless otherwise requested. Do this, and the poor can then be vaccinated, when, where, and by whom they please.

A measure of this kind will meet with the hearty co-operation of the public and the profession; and vaccination will, without any trouble, very soon become universal.

By the following proposed register, a Registrar can at once and at any time, see who are and who are not vaccinated, or have claimed an exemption, especially in January and July. If neither vaccination nor exemption be registered, legal proceedings can easily be instituted.

I am, etc.,

T. S. FLETCHER,

Bromsgrove, November 27, 1862.

*Vaccination Register.*

1	2	3	4	5	6	7	8
No. in this and the Register of Births to correspond.	Date of birth.	Name.	Address.	Date of registration of vaccination, termination, exemption, or death.	Date of temporary claims of exemption.	Name and address of vaccinator, and fee, if any, paid.	Date, name, and address of the re-vaccinator, and fee, if any, paid.

This is the only book that would be required.

*SCHEDULE A.—Vaccination Notice Paper.*

No. in the Vaccination Register.

To the parents or persons having the care or custody of , the child of , of .

I give you notice and require you to have the following vaccination certificate filled up, and registered at my office, before the child is six months old.

Dated day of , 186 .

Name.

Registrar of the district of.

*Certificate of Vaccination.*

The above child was\* on the day of ; and it was examined by me on the day of , 186 . The vaccination has taken successful effect.

+ Name.

Title.

Address.

\* State if vaccinated or gratuitously vaccinated.

+ If inspected by a qualified pupil, insert name, and for whom.

The following is only required in cases of  
*Gratuitous Vaccination.*

The above child was gratuitously vaccinated at my request.

+ Name.

Address.

*Receipt for Gratuitous Vaccination.*

No. in the Vaccination Register.

The Registrar of , has paid me for the gratuitous vaccination of , the child of , of .

Dated day of , 186 .

Name.

Address.

† Parent or nurse in charge of the child.

If vaccination is not gratuitously performed, cut off the schedule below the vaccination certificate, and destroy the remainder. If gratuitously, cut it off above the receipt for gratuitous vaccination.

Parents and others (and not medical men) should be expected to register the various certificates. This they might do by post, free of expense. The medical man should fill up and retain the receipt till paid.

*Claim of Exemption.*

For the following reason, I claim an exemption from having , the child of , vaccinated, and the vaccination registered.

Reasons:

Dated day of , 186 .

Name.

Residence.

Address of the child in full.

THE ROYAL TRIPLE-BIRTH DONATION. The Rev. S. B. Craig, of the Mariners' Church, Hull, has received the commands of her Majesty the Queen to forward to the Rev. Stewart Craig the enclosed post-office order for £3, payable to him, and to desire that he will have the goodness to hand the amount to Mrs. Harriet Harding, as a donation from her Majesty, to assist her after her confinement of three children at one birth; that circumstance having been brought under her Majesty's notice in consequence of an application from Mr. Locking in Mrs. Harding's behalf. Buckingham Palace, Dec. 20, 1862. (*Hull Packet*.)

CERTIFICATES OF LUNACY. The most unhappy of the professions in its appearances in public, is once again the object of general comment and satirical denunciation. If Æsculapius doth still preserve a watchful eye over his earthly children, we fear that he must often be blind, if the gods can weep, from the tears shed over his undergenerate but very unfortunate race. At the same time he must learn, even from what is at present going on, that the institution he has the credit of founding had in it a soul of truth of some depth, or it had never lived till this hour, buffeted as it has been, sneered at, scorned, subjected to every hardship, asked questions which could never be answered, insulted for giving negative replies, implored to do labours at any price that could never be done, and then denounced for explaining the impossibility of the impossible. He must see in his invention the figure of a living thing, but sadly shattered now, and wrung with torture terribly; a thing to be doubted these many years to come, to have to undergo long penance and reformation, and still to live and still to come out in the end very strong, very powerful, as fair as all else amongst which it moves, an absolute science.

## Medical News.

**APOTHECARIES' HALL.** On December 24th, the following Licentiates were admitted:—

Cass, William Leonard, Goole, Yorkshire  
Lindsay, James Murray, Queen's Road, Grove Lane, Camberwell  
Martin, Adam Rae, Rochester  
Peacock, Albert Louis, Huntingdon  
Swales, Peter, Helmsley, Yorkshire  
Young, Francis, 114, Carlton Road

### APPOINTMENTS.

ANDERSON, John, Esq., appointed Junior House-Surgeon to the Manchester Royal Infirmary, in the room of W. O. Jones, Esq.  
BLAKE, Valentine W., Esq., re-appointed Honorary Surgeon to the Birmingham and Midland Counties Lying-in Hospital.  
BROWN, Alfred, Esq., appointed Consulting Surgeon to the Wandsworth Dispensary.  
EASTLAKE, Henry F., M.D., appointed Accoucheur to the St. Mary-lebone General Dispensary, in the room of A. J. B. Squire, M.B.  
\*HEATH, Christopher, Esq., F.R.C.S., appointed Lecturer on Anatomy in the Medical School of the Westminster Hospital.  
\*HOLTHOUSE, Carsten, Esq., F.R.C.S., appointed Lecturer on Surgery at the Westminster Hospital Medical School.  
JONES, William O., Esq., appointed House-Surgeon to the Manchester Royal Infirmary, in the room of W. R. Heath, Esq.  
\*ORFORD, William C., Esq., re-appointed Honorary Surgeon to the Birmingham and Midland Counties Lying-in Hospital.  
ROE, Edwin H., Esq., appointed Physician's Assistant to the Manchester Royal Infirmary, in the room of C. H. Braddon, M.D.  
THOMPSON, Reginald E., M.B., appointed Physician to the St. George's and St. James's Dispensary, in the room of J. H. Stalard, M.B.

### POOR-LAW MEDICAL SERVICE.

BRADDON, Charles H., M.D., to be Resident Assistant Medical Officer to the Brydget Street Workhouse, Manchester.  
\*POLLARD, James, Esq., to the St. Mary Church District of the Newton Abbot Union.  
RICHARDSON, Daniel, Esq., to the Northern District of the parish of Brighton.  
\*WEAVER, Frederick P., M.D., Medical Officer and Public Vaccinator to the Frodsham District of the Runcorn Union.

### ROYAL NAVY.

CALDWELL, J., Esq., Assistant-Surgeon H.M.S. *Mars*, to be Surgeon.  
COGHILAN, Thomas, M.D., Assistant-Surgeon H.M.S. *Beagle*, to be Surgeon.  
DAVIDSON, James, M.D., Surgeon, to the *Necance*.  
HUDSON, John, Esq., Assistant-Surgeon H.M.S. *Cumberland*, to be Surgeon.  
WILLES, George J., Esq., Surgeon, to the *Egmont*.

### VOLUNTEERS. (A.V.=Artillery Volunteers; R.V.=Rifle Volunteers):—

HALKJARD, H., Esq., to be Surgeon 31st Lancashire R.V.  
RICE, J., Esq., to be Surgeon 3rd Middlesex A.V.

### DEATHS.

BEVAN. On December 24th, 1862, at Newland, Gloucestershire, aged 77, Jane H., widow of Robert Bevan, M.D., Monmouth.  
BOSSY, Peter, Esq., Surgeon, late of Woolwich, at Worthing, aged 56, on December 22nd, 1862.  
\*EVANS, David, Esq., at Belper, Derbyshire, aged 82, on November 20, 1862.  
KNOX, Robert, M.D., at Hackney, aged 69, on December 20, 1862.  
MAILLARD, John W., Esq., late Deputy Inspector-General of Hospitals, Madras Army, at Craik, Fifeshire, aged 56, on Dec. 19th, 1862.  
RUTLEDGE. On November 21st, 1862, on Minicry island, from the wreck of the *Colombo*, aged 20, James Heydon Rutledge, Ensign 6th Regiment, only son of James Rutledge, M.D., of George Street, Hanover Square.  
THOMPSON. On December 26th, 1862, at Cheltenham, Stewart Thompson, Esq., Madras Civil Service, youngest son of William Thompson, M.D., of Lisburn, Ireland.  
WOODWARD. On December 26th, 1862, at 81 Cambridge Street, Sophia, widow of Thomas C. Woodward, Surgeon, late of Penton Mewsey, Hants.

**GARIBALDI AND HIS WOUND.** The voyage and the open and mild air of Caprera have already contributed much to the health and spirits of the invalid. He congratulated himself often on being able to return to his solitude, which enables him to take open air exercise. The wound has begun to heal; the swelling of the foot is almost gone; the rheumatic pains are hardly felt.

**MEDICAL SCHOOLS LANCASHIRE FUNDS.** Several of the London schools have raised subscriptions for the Lancashire operatives. St. Mary's Hospital leads the way, we believe, in the work of benevolence; St. Bartholomew's, Guy's, and we hope other hospitals have done likewise.

**AMERICAN ARMY SURGEONS.** As a general thing, the older surgeons have been broken-down political hacks, who had no business at home, and therefore could carry with them no practical experience into the army. Then, again, a great proportion of the surgeons are young men. Many of this class are talented and well educated, theoretically; and, under the guidance of men of more mature years, will come to be ornaments to their profession. These young men, I know, would gladly avail themselves of the practical experience of older men. There is also a class of ignorant men, who gained their appointments by political influence, which neither time nor circumstances can alter for the better: they are not capable of improving by experience. (*American Medical Times*.)

**SHEPPARD ASYLUM AT BALTIMORE.** This institution was founded by the late Moses Sheppard, a wealthy merchant of the Society of Friends, who, several years before his death, conceived the project of testing the curability of unfavourable cases of insanity, by a more liberal expenditure of money than the friends of most asylums would reasonably permit. To this end Mr. Sheppard, having no relatives, left his whole fortune, amounting to six hundred thousand dollars, to found and maintain an experimental institution for one hundred patients. After several years of careful consideration, the trustees of the Sheppard Asylum have commenced the construction of their building, on a plan submitted by Dr. Brown, who now studies the organisation and management of European asylums, to report whatever may serve to carry out the humane purposes of the benevolent founder of this unique institution. Dr. Brown, after having visited the most celebrated asylums in Great Britain, Holland, Germany, Switzerland, and France, expresses regret at having found, thus far, but inconsiderable rewards for the commendable liberality of the Board he represents. (*Dr. Lee's Correspondence*.)

**AGES OF THE NOBILITY.** It appears from *Who's Who* in 1863, that the eldest duke is the Duke of Cleveland, who is 74 years old, and the youngest the Duke of Norfolk, aged 15; the eldest marquis is the marquis of Lansdowne, 82, the youngest the Marquis of Ely, 13; the eldest earl is the Earl of Charlemont, 87, the youngest the Earl of Charleville, 10; the eldest viscount is Viscount Combermere, 89, the youngest Viscount Downe, 18; the eldest baron is Lord Sinclair, 94, the youngest Lord Rossmore, 11; the eldest member of the Privy Council is Lord Lyndhurst, 90; the youngest Earl Spencer, 27; the eldest member of the House of Commons is General Hon. Sir Hugh Arbuthnot, member for Kincardineshire, who is 83, the youngest Mr. Reginald A. Vyner, the member for Ripon, 23; the eldest judge in England is the Right Hon. S. Lushington, aged 80, the youngest Mr. Baron Wilde, 46; the eldest judge in Ireland, Chief Justice Lefroy, 86, the youngest Mr. Justice Keogh, 45; the eldest judge in Scotland, the Lord Justice General, 69, the youngest the Lord Justice Clerk, 52; the eldest archbishop is the Archbishop of Dublin, 75, the youngest the Archbishop of York, 43; the eldest bishop is the Bishop of Exeter, 85, the youngest the Bishop Designate of Gloucester and Bristol, 43; the eldest colonial bishop is the Bishop of Toronto, 83, the youngest the Bishop of Ontario, 37; the eldest baronet is Sir Tatton Sykes, 90, the youngest Sir George R. Sitwell, 2; the eldest knight is General Sir James L. Caldwell, 92, the youngest Sir Charles T. Bright, 30.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY.**.....Royal Free, 2 P.M.—Metropolitan Free, 2 P.M.—St. Mark's for Fistula and other Diseases of the Rectum, 1.15 P.M.—Samaritan, 2.30 P.M.—Lock, Clinical Demonstration and Operations, 1 P.M.

**TUESDAY.**.... Guy's, 1½ P.M.—Westminster, 2 P.M.

**WEDNESDAY.**...St. Mary's, 1 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.

**THURSDAY.**...St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—London, 1.30 P.M.—Great Northern, 2 P.M.—London Surgical Home, 2 P.M.—Royal Orthopaedic, 2 P.M.

**FRIDAY.**..... Westminster Ophthalmic, 1.30 P.M.

**SATURDAY.**... St. Thomas's, 1 P.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**MONDAY.** Medical Society of London, 8.30 P.M. Mr. Hancock, "On the Superiority of Chopart's Operation and Excision of the Ankle over any other Method, in all Cases admitting of their performance."—Entomological.—Epidemiological.

**TUESDAY.** Pathological, 8 P.M. (Anniversary).—Photographical.—Ethnological.

**WEDNESDAY.** Obstetrical Society of London, 8 P.M. Anniversary Meeting. Address by the President, Dr. Tyler Smith; Paper by Dr. Aveling, Sheffield.—Geological.

**THURSDAY.** Royal, 8.30 P.M.—Antiquarian,

**FRIDAY.** Astronomical.—Archaeological Institute.

## TO CORRESPONDENTS.

\* \* All letters and communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen St., Lincoln's Inn Fields, W.C.

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

**S. O.**—It is generally understood that Princess Alice's confinement will take place in April.

**THE TITLE OF M.D.**—A correspondent asks, whether a physician who has no degree of Doctor of Medicine, is justified in signing himself M.D.? The answer is plain and undoubted. He has no right whatever. More than this; he is, there can be little or no doubt, liable to prosecution under the Medical Act, for assuming a title which he does not possess. We have already said: that, under the present ethical condition of medical affairs, we think no professional man can refuse to give the courtesy-title of Dr. to any physician—licentiate of a College of Physicians—who chooses to claim it; and we have given the reasons of this opinion of ours. But this assumption of the courtesy-title of Dr. is a vastly different thing from actually signing M.D.—*Doctor Medicinae*—to one's name, without possessing an University diploma. The physician, non-diplomatized, who designates himself *Doctor Medicinae*, commits a most unjustifiable act—one which, as we believe, renders him liable to legal prosecution under the Act.

**HISTORY OF THE PARISIAN MEDICAL SOCIETY.**—This society was founded in the year 1837, by a few gentlemen, after issuing the following address:—

"The reputation acquired by the medical school of Paris attracts to this city numerous foreigners, many of whom find that in a foreign language it is exceedingly difficult to communicate their observations to others with that clearness and precision which a scientific subject demands; hence they are almost precluded from entering into the discussions of those societies which at present exist. They have also discovered that there are no ready means of consulting the numerous journals published in their own countries; and that while prosecuting their profession abroad, they incur the risk of neglecting its advances at home. Under these circumstances, several gentlemen, who have long experienced the utility of such institutions, conceived the idea of establishing a society in Paris, having two objects: first, the reading papers and discussing topics connected with medicine in the English language; and secondly, procuring medical journals for circulation amongst its members. A meeting having been called, and the above objects stated by the chairman, the following gentlemen resolved to form themselves into a society for the purpose of carrying them into effect:—Dr. J. H. Bennett (now Professor of Medicine in the University of Edinburgh), Dr. J. Cartmell, Dr. C. Cogswell, Mr. G. Cooper, Dr. D. Embleton, Dr. J. A. Fraser, Mr. R. M. Glover (subsequently Dr. Glover, now deceased), Mr. J. Godfrey (Senior Surgeon to the Bristol Hospital, lately deceased), Dr. J. Houseman, Dr. S. Hunter, Dr. A. Lyszczyński, Dr. G. Minchin, Dr. J. Morison, Mr. J. Ozanne, Dr. S. Palmer, Dr. S. J. B. Richardson, M. Roger, Interne at the Hôtel-Dieu (now Physician to one of the Hospitals, Paris), Dr. J. Shannon, Mr. A. J. Walsh (now practising as a Physician in Dublin), Mr. J. Williams (now Dr. Joseph Williams of London). It was resolved that this association should be called the Parisian Medical Society; and several resolutions were proposed and agreed to, having reference to its constitution and government. Every information regarding the society will be given to those gentlemen desirous of becoming members, on application, either personally, or by letter post paid, to Dr. Cogswell, No. 20, Rue Neuve Racine, before the 1st of January, 1838, early in which month the Society's meetings will commence."

**E. T.**—Our correspondent will find his question answered in the following words of the *Chemical News*.

"The terms *deodoriser* and *disinfectant* are sometimes—we might say, generally—used with most unscientific laxity. A substance which is merely a deodoriser is often called a disinfectant; and both words are often applied to bodies which are only antiseptics. It is true that there are some things which are at once both deodorisers and disinfectants, as is the case with the permanganates of potash and soda. These bodies, by easily parting with their oxygen, hurry organic matter in a state of decomposition to the last stage of oxidation, so destroying the compounds which possess the repulsive odours evolved in the course of decomposition, and also, no doubt, burning up the effective agents in the production of some diseases. They have, too, the effect of decomposing any sulphuretted hydrogen or sulphide of ammonium which may have been produced in the decomposition of organic matter. Nor, so far as water is concerned, do the results end here. In the case of water which may have become contaminated with lead, Mr. Condy has shown that the permanganates have the power of converting the protoxide of lead which the water holds in solution into the insoluble peroxide, and so effectively removing every trace of the metal."

**A QUESTION REGARDING CONSULTATIONS.**—SIR: As a member of the Association, I beg to ask your opinion on the following point. A medical man, being asked by one of his own patients to call me in for consultation, refuses to meet me, on the ground of my being considerably his junior. The qualifications of this gentleman are as follows:—L.S.A. London, 1849; M.R.C.S., 1860. My qualifications are:—L.R.C.S.I., 1855 (January); L.S.A. London, 1857; M.D. Queen's University, Ireland, 1861. Has a medical man any right to refuse to meet another in consultation for such a reason? In case of such refusal, what course should be pursued? I should be obliged by a reply in the "Answers to Correspondents" in your JOURNAL. I enclose my name and address on the other side.

December 20th, 1862. I am, etc., Q. U. I.

[We believe that, according to the rigid doings of the stiff physicians of the gold stick age, it would not have been considered etiquette for a junior physician to be called in to consult in a case upon which a senior physician was in attendance. But such doings are now something like matter of history. We apprehend that no physician, nor any other medical man in London, would object to meet any other physician in London, merely because he was his junior. The refusal referred to by our correspondent, made on the grounds of age and standing, is quite behind the times and the liberal spirit of the age. We need hardly add, that there is no right beyond the force of modern ethical opinion to bring a man to such a meeting; and we know of no other remedy for the thing beyond what can be administered by the voice of professional opinion on the subject. EDITOR.]

A. T.—The term *hyperchromatopsie* is used by the French to indicate an anomaly of vision, under the influence of which the patient is led to attach ideas of colours to certain objects or certain forms, which have no real connexion with colours.

**PRESCRIBING BY MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.**—SIR: In reply to your correspondent, "A General Practitioner", in your last number of the *BRITISH MEDICAL JOURNAL*, and for the information of my brother practitioners, I beg to refer them to some printed observations issued by the Apothecaries' Society of London, with respect to evidence to be adduced in support of an action in the County Court, for the recovery of the penalty incurred for practising as an apothecary without legal qualification.

"The practice of an apothecary consists in attending and advising patients afflicted with diseases requiring medical treatment, prescribing, compounding, and supplying medicines for their cure or relief; for instance, diseases of the brain, the lungs, the heart, the stomach, the liver, and the bowels, when the disorder is unattended by any external wound, sore, or tumour; and when medical treatment, unaided by any manual operation, is called for. The following observations of Mr. Justice Cresswell, in the case of the Apothecaries' Company v. Lotting, will be read with advantage. 'Now, I apprehend that an apothecary is a person who professes to judge of internal disease by its symptoms, and applies himself to cure that disease by medicines. A surgeon may lawfully do this if the medicines are administered in the cure of a surgical case; if, for instance, in the case of a broken leg, it becomes necessary to administer medicine; but, on the other hand, if a surgeon takes upon himself to cure a fever, he steps out of his lawful province, and is not authorised to administer medicine in such a case. But then it is said, if he did not supply the medicine as a surgeon, still he did not supply them as an apothecary, but as a chemist. But a chemist is one who sells medicines which are asked for, not to select medicines, and determine on which he ought to give.' A bill is not absolutely necessary, as evidence can be given that the patient was attended as medical men ordinarily do attend, and that the services were not gratuitous."

I have no doubt that Mr. Upton, the clerk of the Apothecaries' Society, will furnish any gentleman with a copy of the printed instructions; and, as quackery among chemists is so common, and the Apothecaries' Act so little understood, I think it would be a prudent step to copy the observations issued by the Society of Apothecaries into an early number of the *BRITISH MEDICAL JOURNAL*.

I am, etc.,

December 22nd, 1862. ANOTHER GENERAL PRACTITIONER.

### SUBSCRIPTIONS.

THE following Laws of the Association will be strictly enforced:—

15. The subscription to the Association shall be One Guinea annually; and each member on paying his subscription shall be entitled to receive the publications of the Association of the current year. The subscriptions shall date from the 1st of January in each year, and shall be considered as due unless notice of withdrawal be given in writing to the Secretary on or before the 25th of December previous. If any member's subscription remain unpaid twelve months after it shall have become due, the publications of the Society shall be withheld from such member until his arrears be paid.

16. The name of no member shall remain on the books of the Association, whose arrears extend over three years; but the omission of the name from the list of members shall not be deemed, either in honour or equity, to relieve any member from his liability for the subscriptions due for the period during which he has availed himself of the privileges of membership.

PHILIP H. WILLIAMS, M.D., *General Secretary*.

Worcester, January 1863.

COMMUNICATIONS have been received from:—Mr. WILLIAM COPNEY; Dr. LATHAM; Mr. H. G. HARDY; Mr. CHRISTOPHER HEATH; Mr. E. L. HUSSEY; Dr. WALKER; Dr. W. R. HILL; Dr. J. GARDNER; Mr. J. VUSE SOLOMON; THE REGISTRAR OF THE MEDICAL SOCIETY OF LONDON; Dr. JOHN DEEDOE; Mr. HENRY DUNCAFE; Dr. C. MURCHISON; Dr. PHILBRICK; Mr. ERASMUS WILSON; Dr. EVANS; Mr. A. MARTIN; Dr. CULLAR; Dr. GRAILY HEWITT; and Mr. C. E. SLOPER.

### BOOK RECEIVED.

Researches on the Nature, Pathology, and Treatment of Emphysema of the Lungs. By A. T. H. WATERS, M.D. London: 1862.

## Aloina.—The discoverers of this

(vide "Edinburgh Monthly Journal of Medical Science for Feb. 1851), the CRYSTALLINE PURGATIVE PRINCIPLE OF ALOES, continue to prepare and supply it. They have the gratification of knowing that the most eminent of the profession prescribe it, to the exclusion altogether of the various kinds of aloes. Orders executed direct or through any Drug house, by T. & H. SMITH & CO., 69, Coleman Street, London, and 21, Duke Street, Edinburgh.

## Peroxide of Hydrogen. (The

New Medicinal Agent.) According to the formula, and of the strength described by Dr. Richardson in a paper read before the Medical Society.

See *British Medical Journal*, March 22, and other Medical Journals. Price 4s. 6d. per lb.

Prepared by A. GARDEN, Operative Chemist, 372, OXFORD STREET, LONDON.

## The London and Provincial

MEDICAL PROTECTION SOCIETY, 43, Lincoln's Inn Fields, London. [W.C.]

PRESIDENT.  
JOHN PROPERT, Esq.

TRUSTEES.

Horatio Day, Esq., Isleworth  
John Propert, Esq., New Cavendish Street  
Henry Sterry, Esq., New Kent Road.

COMMITTEE.

John Armstrong, M.D., Gravesend  
A. B. Barnes, Esq., King's Road, Chelsea  
S. A. Bindley, Esq., Birmingham  
J. M. Bryan, M.D., Northampton  
J. M. Dempsey, Esq., Goswell Street  
R. Dunn, Esq., Norfolk St., Strand  
R. D. Edgecumbe, Esq., Shaftesbury Crescent  
F. Godrich, Esq., New Brompton  
J. H. Gramshaw, Esq., Gravesend  
John Harrison, Esq., Chester  
Edwin Hearne, M.B., Southampton  
C. F. J. Lord, Esq., Hampstead

W. C. Meates, Esq., Chester Sq.  
J. Sharp, Esq., Grosvenor Street West, Faxon Square  
Thos. R. Simonds, Esq., Brighton  
R. G. F. Smith, Esq., Portsmouth  
Arthur B. Steele, Esq., Liverpool  
Alexander Richard Stokes, M.D., Liverpool

H. Terry, Esq., Northampton  
Thos. Taylor, Esq., Birmingham  
T. G. Traquair, M.D., Ecclestone Square, Pimlico  
Thomas B. Winter, Esq., Brighton  
John Weaver, Esq., Chester

TREASURER—Robert Dunn, Esq.

BANKERS—Messrs. Gosling and Sharpe, 19, Fleet Street.

SECRETARY—John Capes, Esq.

The objects of this Society are—

1st. To provide a safe and efficient medium by which the Medical Profession may secure more certain and regular payment for their services; with every consideration for the convenience of those who are willing, but unable directly to discharge their liabilities; with rigour from those who are able but have not the disposition to remunerate medical men.

These ends are to be accomplished without interfering with the valuable time of the Members of the Profession, or exposing them to the unpleasantness which necessarily attends applications for money, or to the uncertainty and risk of employing private collectors.

2nd. To assist Members with information and advice in the purchase and sale of Practices.

3rd. To raise a Benevolent Fund by devoting to that object the profits arising from the general operations of the Society.

The Society consists of qualified Medical Practitioners only. Annual Subscription, One Guinea; a Firm, consisting of two Partners, a Guinea and a half; a Firm of three Partners, Two Guineas. Fixed rates of Commission are also charged on business transacted. The general business is carried on by a staff of officers at the Central Office, 43, Lincoln's Inn Fields, together with trustworthy employes appointed in town and country, the whole of whom are under the direction and superintendence of the Committee.

The Metropolitan Members of the Committee, with the Trustees, are responsible for all moneys received by the staff.

## For Varicose Veins and Weak-

NESS. Very superior SURGICAL ELASTIC STOCKINGS and KNEE-CAPS, on a New Principle, pervious, light in texture, and *inexpensive*, yielding an efficient and unvarying support, under any temperature, without the trouble of Lacing or Bandaging. Likewise, a strong low-priced article for Hospitals and the Working-classes.

ABDOMINAL SUPPORTING BELTS for both Sexes, those for Ladies' use, before and after accouchement, are admirably adapted for giving adequate support with EXTREME LIGHTNESS—a point little attended to in the comparatively clumsy contrivances and fabrics hitherto employed.

Instructions for measurement and prices on application, and the articles sent by post from the

Manufacturers.  
POPE and PLANTE, 4, Waterloo Place, Pall Mall, London.  
The Profession, Trade, and Hospitals supplied.

# General Remarks

ON THE

## PRACTICE OF MEDICINE.

BY

P. M. LATHAM, M.D.

### THE HEART AND ITS AFFECTIONS, NOT ORGANIC. (*Continued.*)

II.—*Number of the Pulse. Is there any certain Number, or any Limit between certain Numbers, that can be assigned as the Standard of Health generally?*

THERE is a good deal in the nature of things without us which might favour the expectation that the things within us would be found to observe a more exact and undeviating order than in fact they do. Thus, prior to experience, it might not be at all unreasonable to expect that the pulse would be numerically the same in every healthy man; that the Heart would contract within the minute a certain number of times, neither more nor less; that at each contraction it would deliver into the arteries a certain quantity of blood, neither more nor less; and that the exigencies of health in all organs of the body would require blood to be thus supplied to them according to one exact measure of time and quantity. But a very little observation directed to the point will be enough to show that the pulse of health differs greatly as to number in several men. One man's pulse will be found to beat twenty beats in a minute more than another man's; while there is no appreciable difference between them of mind or body, and none of habit or pursuit, to account for it. In some, the pulse habitually reaches 80; in some, it falls short of 60; and in some, and those the majority, it is found at various numbers intermediate between the two. But which tells the best for health and long life—a pulse between 50 and 60, between 70 and 80, or between 60 and 70—my own experience has not yet informed me.

But while it is true that there is no general law of health requiring the pulse to be of any certain number, and that the same in all men; and true also that the pulse may take a wide numerical range in several men, and be consistent with health in them all; yet is there not some certain number which, being found in the great majority, may be deemed healthy by preeminence? The world is very curious about this matter; and physicians have made it so by their constant habit of counting the pulse. Therefore they are bound to give the best answer they can to its questioning.

People in general have no notion of the sort and amount of evidence often needed to prove the simplest matter of fact. To the question—What is the numerical standard of the healthy pulse?—some might answer 68, some 70, and some 72. But I am convinced that, as an ascertained fact, nobody knows

anything about it. The least sufficient proof of it which can be conceived would be so laborious, and so beset with possible fallacies at every step, that the result would hardly be trustworthy. It would require that a hundred people at least should be the subject of experiment; and, considering that they would stand as the representatives of all mankind, a hundred is few enough. Then these hundred men should be all nearly of the same age, and all in perfect health constantly and every day as long as the experiment lasted; and they should be under observation for several weeks at least, and in the meantime have the number of their pulse noted and recorded day by day and several times a day. These are a few only of the conditions which the experiment would demand. Lastly would come the formidable calculations of arithmetic, and its severe result, announcing, perhaps, that the number of the pulse in a healthy man at the prime of life was 1½ beats in a second.

Now, to those who walk about with their eyes open, objects often present themselves with a fidelity and truth which are too apt to suffer diminution and loss when the same objects are submitted to more curious experiments. For Nature herself is wise and discriminative in the conditions she imposes for obtaining different sorts of knowledge; and thus oftentimes she is sternly practical, requiring that what is intended for *use* should be learnt *by use*; bringing all that can or need be known within the reach of daily observation, and presenting it as her own free gift to common sense.

From use, and the daily habit of counting the pulse, all that concerns its numerical healthy standard must have taken some orderly shape in the minds of most physicians. The following is the shape which it has taken in mine. Perhaps, in such a matter, I may appeal to my own case, and not be blamed for egotism. The oracle of old made it the top of wisdom to know oneself, but did not fix the credit due to that fragment of self-knowledge which enables a man to keep count of his own pulse. My own pulse, when I am quite well and quite free of excitement both from within and from without, is 56. And this number of 56 I meet with in others who are in good health often enough to show that the thing, taken alone, means nothing wrong; but seldom enough to show that it is not common. The same I would remark of the pulse of 80. I find it often enough in healthy people to make me sure that, taken alone, it denotes no evil; but seldom enough to make it uncommon. A pulse which is less in number than 56, or more than 80, is so rarely the habitual pulse of health, that I am obliged to regard it as exceptional, and can make no comment upon it from my own experience. Practically, then, and saving exceptions, I am wont to consider 56 and 80 as the two extremes consistent with health. But truly there are eminent odds between them.

Surely somewhere between these extremes, and *distant* from both, are the numbers at which the pulse is most frequently found in the healthy. Now *equidistant* from both is 68; but one would not venture to fix upon this as the number of health by preeminence. Thus far, however, one might safely go. The difference between 56 and 80 is 24, or three times eight. Add eight to one extreme, 56, and deduct eight from the other extreme, 80; and eight

will remain intermediately, including the numbers between 64 and 72. And between these numbers (it would come as near the truth as experience can bring us to say) the pulse is found in the great majority of healthy people. But the *centre* equidistant between 64 and 72 is 68: therefore it may be added, that the pulse of health hovers about 68, being as often a trifle more as less, and less as more.

This, then, is the best answer I have to give to the general question, What is the numerical standard of the pulse in health?

*Have Individuals a certain Number of the Pulse as their own Standard of Health?*

But, while there is no general law of health requiring the pulse to be of a certain number, and that the same in all men, yet may there not be a special law or (something like it) a necessity of health in each individual fixing his pulse to some certain number, and keeping it constant to the same? Observation must settle the question; and mine leads me to settle it in the affirmative.

It has been seen what a wide numerical range is consistent with health. Now, whatever be the habitual number of the pulse within that range in the *healthy* man, it is, as far as I see, always the same so long as body and mind are at rest and under no present excitement. If its number be 60, it is always 60; if 70, it is always 70; if 80, it is always 80. But a very little stir of body, a very little emotion of mind, even the stimulus of a temperate meal, is enough to add a few beats a minute to the pulse of the healthiest man; and as soon as body or mind is at rest again, or digestion is over, his pulse settles down to its habitual number.

The causes of excitement here contemplated are independent of disease. They belong to the occurrences of every day, such as even many times every day must and do accelerate the pulse inevitably and innocently, and then leave it to reach its standard number again. And it always *does* reach it, if the man be in health.

Observe, *by health* I here mean not merely a state of exemption from positive disease, but of exemption too from those caprices of feeling and function which are called nervous, and are ever making the pulse run wild, and hardly allowing it to remain at any given number for an hour together. Of health thus understood, it is a chief characteristic that the pulse is habitually constant to a certain numerical standard, and that it does not deviate from it but for adequate and appreciable causes. These causes, considered comprehensively, involve within them the whole pathological meaning and import of the number of the pulse both as a symptom of disease and guide to practice.

*Increased Number of the Pulse in Diseases.*

There is nothing that a man can feel or suffer—feel as a passing incident of health, or suffer as a constant inseparable element of disease, which may not be put down for a cause of accelerated pulse. Of the incidents of health more need not be said at present. But of diseases, whatever be their kind, if by any avenue of sympathy they can reach the heart, they all accelerate the pulse. All inflammations, all fevers, do so. The inflammation which comes on abruptly from injury, accident, or exposure, and

overtakes men in the midst of good feeding and rude health, and calls for bloodletting to arrest it,—this, preeminently the inflammation of strength, accelerates the pulse. Again: the inflammation which comes from nothing seen or known, but arises and proceeds furtively in constitutions bad by nature, and made worse by poverty and wretchedness, and admits no bloodletting for its cure,—this, preeminently the inflammation of weakness, accelerates the pulse. The fevers (call them by what name you please) which dominated in the hospitals of London thirty years ago, which bore and required and were properly treated by such remedies as exercise restraint upon the movements of the Heart and arteries—by calomel, and antimony, and purgatives, and not unfrequently by bloodletting in its several kinds; also the fevers which now dominate in the same places, and which will bear no such remedies and no such handling, and are properly treated by whatever can raise, sustain, and stimulate—by wine, brandy, ammonia,—these, preeminently the fevers of weakness, and those, preeminently the fevers of strength, both alike have among their symptoms the frequent pulse.

In short, whatever be the nature of the disease, if the Heart feel it at all, however diversely it may otherwise show what it feels through the pulse, whether in rendering it stronger or weaker, harder or softer, larger or smaller, than natural in several cases, it will surely in all of them render it more frequent. Often the Heart is a more delicate test of something wrong within the man than his own consciousness. His Heart is beforehand with him. It tells of disease covertly but surely progressive by the unnaturally frequent pulse, while his own feelings persuade him that he is well. At length, after the lapse of weeks or even months, the constitution is awaked, as it were, to a conscious alarm, and, by its fever and its nervous irritation, confirms what the Heart has forefelt and foretold by the frequent pulse. Tuberculous disease often forms and germinates and matures under these conditions.

*Difference between the Number of the Pulse and the Quality of the Pulse, as Signs of Disease, and what each respectively imports.*

Such are the facts, stated generally. We come now to consider their pathological and practical import. This greater number of the pulse in diseases, whence comes it, and what does it mean? What is the nature and amount of help which it contributes towards our knowledge and treatment of the case in hand? For surely the number of the pulse ought to have a vast deal to teach us, seeing what a point we make of ascertaining it in every instance. The pulling out of the watch, and the deliberation which follows, must appear to the patient at least the most solemn part of the interview with his physician. And, if this grave business has no great use in it, it becomes a mighty foolish pretence. Far be it from me to allow that it is so. But let us inquire and see. One thing is plain to common sense; namely, that the number of the pulse is just the sort of symptom which ought to be pushed as far as it will fairly go, and relied upon as far as it can be safely trusted; for the information it has to give, being in itself so easily ascertained and so indubitable, that no two men can disagree about it, who are able to count.

Now the frequent pulse, being equally the accompaniment of numerous diseases different in kind, cannot take its origin from any of those proper elements which severalise them. It is proper to no disease; yet its constant presence in almost all forbids it to be regarded as an accident in any. Moreover, the frequent pulse is a passing event of health, as well as a necessity of disease. Its origin, therefore, must be sought in something common to both—something belonging to life and sympathy; in their widest sense—something without which neither action nor feeling nor suffering can exist—something without which there could be neither health nor disease.

For the sake of illustration, let me here anticipate a part of our subject which will be considered hereafter in its turn. Let me take the *qualities* of the pulse and their meanings, and put them in contrast or comparison with the *number* of the pulse and its meanings, and illustrate one by the other. The quality of hardness in the pulse has most important meanings as a symptom of disease; but in health I am not aware that the pulse ever assumes that quality, or suffers that quality to be forced upon it. Heat, exercise, and stimulant drinks will for a time augment the frequency and force of vascular action. But mere force of vascular action is a different thing from the quality of *hardness* in the pulse. This they cannot produce unless they first produce disease. I am not aware that by any possible contrivance we can make a soft pulse a hard one at will. In order to the change, there must first be disease. Seeing, then, that this quality of hardness in the pulse has no existence apart from disease, I infer it to be in its very nature essentially morbid.

But in health the number of the pulse is continually found to transgress its habitual standard from obvious causes. Every sense and sensation, every moral feeling and faculty of the mind, opens an avenue to impressions which travel to the heart, and may so operate upon it as to raise the frequency of the pulse *without first producing disease*. Thus it is that the ordinary casualties of life accelerate the pulse by exciting thoughts, feelings, and perceptions which are pleasurable or painful in an unusual degree. And thus it is that we can accelerate the pulse at will by subjecting the man to influences capable of being felt above measure mentally, morally, or corporeally. Seeing, then, that this numerical frequency of the pulse, unlike its quality of hardness, may exist apart from disease, I conclude that it is not in *its own nature* essentially morbid.

But though it is not in itself essentially morbid, yet it is found in constant connection with diseases, and is reckoned among their symptoms. The question then arises, *how* is the number of the pulse connected with diseases?

There is good reason, then, for believing that frequency of pulse is produced in diseases after the same manner that it is produced in health; and that diseases operate upon the Heart so as to accelerate the pulse, *not as diseases*, but as simple irritants. They can and do operate upon it as diseases, when they change the *quality* of the pulse; and they can and do operate upon it as simple irritants when they change the *number*. And they may do both the one and the other in the same instance.

In almost all diseases (it has been already said)

the pulse is raised above its habitual numerical standard. But no disease can be mentioned in which it is always or so far of a certain number, that the nature of the disease can be taken from the number of the pulse. On the other hand, it is only in particular diseases that the pulse assumes certain qualities. But then the quality may be so distinct and unequivocal, and so commonly annexed to the disease, as to admit it to be reckoned among its symptoms. This is the case with the quality of hardness in the pulse of inflammation.

How and whence comes this difference? It comes because the number of the pulse has nothing to do with the disease as such, but the quality of the pulse has everything. It comes because the number of the pulse is annexed to the moral, nervous, vital conditions of the man, which may be influenced by several diseases in the same way, or by the same disease in several ways, according to the varying susceptibility of individuals; but the quality of the pulse is annexed to the nature of the disease, which is the same in all men.

It is, then, the difference of the thing signified which separates and contrasts the quality and the number of the pulse as symptoms. The quality gives information concerning the nature of the morbid processes going on. The number tells nothing concerning these processes, but rather intimates how the system at large is affected by them, be they what they may. The quality notifies disease simply; the number how the constitution bears it, whether it feels it in that degree in which (so to speak) it ought to feel it, or feels it less than it ought and is passive under it, or more than it ought and is exorbitantly affected by it.

With this clue we are prepared to deal with the subject more closely. And, albeit the number of the pulse tells nothing of the nature of any disease; albeit it guides neither the choice nor the aim of any remedy, so far as that remedy is counteractive of morbid processes going on, yet it is not without reason that physicians are ever counting it and making much of it. For it denotes things more important than the diseases themselves, viz., how life and the springs of life are affected by them, whether they will hold out, or whether they will fail. And in treatment it guides us to things just as important as the very remedies, if there be any such, which are directly curative; viz., the force and extent to which they can be curatively employed.

But nothing can be taken for *absolutely true* in practical medicine. Hence they who profess to teach others out of their own experience, should be careful of using language which may imply more than that experience will justify. At the same time, they must not be continually dealing in doubts and reservations, and so bring their experience below its value by seeming to have small confidence in it themselves. The truth which medicine is concerned with is a *truth of degrees*; the same, nevertheless, which the moral world is governed by. Wise men seek it and cultivate it, and make the best of it. In medicine there is small philosophy, and no use in making it seem less than it is.

That the pulse is constant to a certain number in each healthy man, is a fact already mentioned, and an important one it is. And this fact, it might be thought, would become a standard of reckoning in each man's disease. But in their ordinary practice,

physicians seldom come to the management of diseases with the knowledge of this fact. Our patients are too often strangers to us until we are called to treat them; and then we cannot take for our standard of reckoning the exact number which belongs to health in the individual man, but can only assume the healthy limit of the generality, and consider that his pulse falls somewhere within it, viz., between 64 and 72.

It is worth a passing notice, how much safety and success in the treatment of present disease are promoted, when the physician has already known his patient in previous health or in previous illness, or in both. Hereditary constitution, and personal constitution and personal habits; hereditary disease, and personal disease once suffered but now past, may leave a perpetual entail of something able to give a shape or colour to every future malady which may happen to a man, and suggest one mode of treatment and prohibit another. I am even persuaded that any single severe attack of disease, and how the patient bears it, and how he gets rid of it, will furnish an exposition of what power there is in him for bearing and recovering from all diseases as long as he lives. And a physician who has had the treatment of him in one such disease, and brought him safely through it, has gained thereby a forecast of much that will surely be found in all future diseases which he may suffer, as well as of the sort of remedies that they will require. If this, indeed, be true, it were well for people in general that they were aware of it. It might cure them of their fickleness in running from one physician to another, and teach them for their own sakes an honest allegiance to the one who, whatever others may know better than he, knows *them* best, at all events.

The health of individuals may differ from the health of the many in some distinct peculiarity, and be sound authentic health nevertheless. And this individual peculiarity of health may impress an inevitable peculiarity upon every disease which the man suffers, and yet leave it not less the same disease as that which bears the same name in the many. The peculiarity of the man's health may be an uncommon frequency or infrequency in the habitual number of his pulse, and this may be carried forward into all his diseases. Thus, whenever he is ill, his pulse will be much more or much less frequent than in just proportion with other symptoms which constitute the disease than experience says it ought to be. And thus I have known some cases in which the unduly slow pulse of health was still the unduly slow pulse in disease, even in severe disease, and the patient has been thought much less ill than he really was. And I have known many cases in which the unduly rapid pulse of health was still the unduly rapid pulse in disease, even in trivial disease, and thus the patient has been thought much more seriously ill than in fact he was.

In the treatment of disease our business is with the individual, and our experience of the many goes to fit us for our dealings with the one. Yet it may not exactly fit us. But if to it be added a prior experience, had of the individual now the subject of treatment, then it becomes a perfect experience, and as nearly infallible as the nature of the things to which it is applied will allow it to be.

## Original Communications.

### DYSCROMATODERMA; OR, DISCOLOURATION OF THE SKIN.

By ERASMUS WILSON, F.R.S.

[Concluded from page 7.]

My third proposition relates to the therapeutical management of these curious complaints, with the view of establishing a principle of treatment. If the theory which I have advanced be correct, if melasma be a consequence of hæmic dyscrasis resulting from a depression of nervous tone; then, the principle of treatment must be, to restore nervous power; to improve digestion and assimilation; and to stimulate the skin to a more healthy local function.

In practice we should direct our treatment, firstly, to the regulation of the digestive and assimilative organs, to establish a healthy basis for further operations, and with the conviction that improvement of digestion and assimilation will directly improve the nutrition of the nervous system, and indirectly the nervous function. Secondly, a comparatively sound state of the nutritive and assimilative functions being established, we should have recourse to those remedies, known as neurotonics, that act directly on the nervous substance, and with the purpose of giving strength and energy to the nervous system. Thirdly, and, concurrently with the two preceding stages of the medicinal course, we may prosecute the local treatment, namely, stimulation of the skin, to restore the healthy tone of the tissues, and their active agents, the local vessels and local nerves.

The treatment which, in my hands, is most successful in restoring the tone and function of the digestive and assimilative organs is, nitromuriatic acid with gentian or orange-peel; a mild sedative aperient, such as equal parts of compound extract of colocynth and extract of henbane, once or twice or three times a week, as may be necessary; or, where the want of action of the alimentary canal seems to depend on nervous irritability, a quarter of a grain of extract of belladonna at bed-time every night; or again where a loaded state of the vessels of the liver is present with a sluggish circulation of the portal vein; then an occasional dose of calomel or blue pill, followed by an aperient draught. When the digestive organs are sufficiently strengthened to bear iron, we shall find an useful remedy in the tincture of the sesquichloride, or in the conjunction of this preparation of iron with phosphoric acid and tincture of orange-peel; or with infusion of quassia.

For specific operation on the nervous system and nerves, the best remedies are: quinine, citrate of quinine and iron; and, lastly, when all has been got out of the preceding remedies that they can give, arsenic; either the liquor arsenici chloridi; the liquor potassæ arsenitis; or the arseniate of soda. The formula which I published many years ago, of the ferro-arsenical mixture, can hardly be improved upon.

For local treatment, the best remedies are: the juniper tar soap, used as an ordinary soap, and well rubbed into the affected parts of the skin, night and morning; or, where additional stimulation is required, frictions, with the hypochloride of sulphur ointment; or, in more inveterate cases, especially of epheles of the forehead and face, pencilling with a solution of caustic potash or carboic acid, one part to four or eight of distilled water, according to the degree of reaction required. The reaction should not amount to more than a slight erythema and simple exfoliation of the cuticle, and the

remedy may be repeated as soon as the skin acquires its natural state, and until the discoloration is entirely removed. The juniper tar soap should be continued during the period of use of the caustic potash and carbolic acid solution, as well as when the simpler process is followed.

In the cases which follow, the greater proportion, indeed almost all, were examples of melanæmia, two only, out of the nine, being instances of leucanæmia; and of the nine cases seven were those of ephelis. The predisposing cause was nervous exhaustion, prostration, and debility, sometimes occasioned by a moral shock, sometimes by sorrow and anxiety, or by fright or over-exertion, or over-active growth; and sometimes by visceral disorder, or by eruptive fever as in the instance of small-pox. The duration of the disease when the cases first came under my notice, varied from one year to twenty.

It may be well, also, in conjunction with the treatment of the disease, to pass in review the general symptoms of melanæmia, as deduced from the reported cases. They may be grouped under three principal heads, nutritive, gastric, and nervous. The symptoms evincing disordered nutrition, are: thinness and sparseness of habit; softness of muscle; pale and discoloured skin. The symptoms denoting weakness of the digestive organs, are: loss of appetite; dyspepsia; weight at the epigastrium; flatulence; sometimes nausea and sickness; sometimes constipation, but, in general, there is little change in the action of the bowels. The symptoms shewing feebleness of the nervous powers, are: debility, languor, lassitude, listlessness, restlessness; depression of spirits; melancholy; nervous irritability; giddiness, dimness of vision; sometimes sleeplessness, headache, feeble action, and palpitations of the heart; loss of energy and courage; in one case there existed nervous monomania; in another there was "misery and despondency." Besides these, the general symptoms of melanæmia, there were other associated symptoms showing the connection between this distressing disease, and disorder of the nervous system, for example: neuralgia; alopecia areata; stearrhea; urticaria; prurigo; and eczema.

In reference to ephelis, one of the commonest of the dyschromata, and a frequent example of melanopathia; it may be well to make a few explanatory remarks. Ephelis is a melasma occurring in well defined but irregular patches, of a size varying from a quarter of an inch to several inches in diameter; it is, essentially, a melasma partialis or melasma figurata, as distinguished from melasma generalis or melasma diffusa, or nigredo cutis. The term "ephelis" takes its origin from the discoloration produced in the skin by the action of the sun, and therefore, signifies simply "sunburn." It belongs to the nosological group of maculæ or stains, and is well defined by Plenck as follows:—"Ephelis est macula fusca, lata, solitaria, vel agminata."

The colour of ephelis varies from a slight shade of brown, or bronze, to the deepest tint of black. It is chiefly met with on the face and neck or backs of the hands, or other parts of the surface that are habitually exposed to the air and light. It is unaccompanied with hyperæmia or any roughness or morbid change in the epidermis, other than the alteration of colour; and is commonly smooth and uniform with the rest of the skin. Its customary seat is the forehead, the upper lip, the cheeks, and the neck; but it is also seen, not unfrequently, on parts of the skin which are ordinarily covered by the clothes.

Ephelis being essentially a brown stain, identical with that which is left on a part of the skin that has been previously irritated and influenced by the heat of the sun, a "macula fusca" as Plenck calls it, it is somewhat jarring to our understanding to read of "ephelis alba," a term applied to that state of deprivation of pigment of the skin which is more properly denominated leuco-

pathia or alphosis partialis vel figurata. Ephelis alba is intended to signify a white patch similar in shape and size to the brown or black patches of ephelis fusca or melasma figurata, and allied to it, in a certain degree, as being a disorder of chromatogenesis.

Plenck makes six genera of Maculæ, as follows:—Maculæ fusca, rubra, livida, nigra, albæ, et incerti coloris; but the true maculæ of the skin may, without inconvenience, be reduced to three; namely, M. fusca, nigra, et albæ. The genus *Maculæ fusca* includes the lighter tints of black, the browns and the yellow; or, as he designates them, fuscedo cutis; ephelis; lentigo; and flavedo cutis. The genus *Maculæ nigra* embraces the deeper tints of black, namely, nigredo cutis; melasma; and melas; and the genus *Maculæ albæ*, albor cutis, and alphas.

Ephelis he denominates liver spot, probably from the hepatic colour of the tint of brown; and lentigo he compares in colour, figure and size, to lentil seeds. "Lentiginis sunt maculæ fusca, quæ, colore, figurâ et magnitudine, lentes referunt." Lentigo, popularly termed "freckles," presents divers hues of yellow, from a bright golden tint to a sallow brown, or a brown verging on green. Freckles are commonly developed on the face and hands under the influence of the stimulus of light and of the rays of the sun; but they are also met with on other parts of the body habitually clothed. They are an appendage of a weak and delicate or irritable skin, and are usually met with in young persons, mostly of fair complexion and of a weak or debilitated constitution.

Plenck divides ephelis into eight species, chiefly in reference to the nature of their cause; for example, he has: E. solaris; ignealis; a vesicatorio; gravidarum; hepatica; dysmenorrhœalis; hæmorrhoidalis; et neonatorum, maculæ luteæ; and, these causes, in different language may be stated as follows: 1. Ephelis from the direct action of an irritant upon the tissues of the skin, e.g., E. solaris, ignealis et a vesicatorio. 2. Ephelis from a reflex action operating on the tissues of the skin, and originating in irritation of the stomach, liver, uterus or other abdominal and pelvic organs; the agent of reaction being the nerves and specially the nutritive or trophic nerves. The same explanation applies to lentigo; freckles may be either the effect of a direct irritant operating on the skin, as in the instance of the sun's rays; or they may be the effect of distant nervous irritations originating in the nervous centre; or in the irritation of internal organs, and very probably of the organs of nutrition. Of the latter kind are the "cold freckles" which are found on the covered parts of the skin in young persons, and in a similar situation in persons of mature age or of advanced life.

The following cases of melanæmia and melasma are taken without selection, chiefly from patients who have consulted me during the last few months.

**CASE I. Melanæmia; Ephelis Frontis et Labii Superioris; Nervous Prostration.** A lady, aged 38, married, the mother of four sons, ranging in age between 10 and 16, is the subject of dark brown stains of irregular form and size situated on the forehead and upper lip.

She is a person of delicate frame; but is at present enjoying better health than for some years past. She dates her loss of health to the birth of her last child, ten years back; she was confined prematurely and nursed her child too long; and suffered subsequently from menorrhagia and disorder of the womb. She has also suffered in health from residence in hot and cold climates; also from long and forced journeys.

Her complexion is sallow; and the conjunctiva is anæmic, brightly white with a dark shade, which gives the whiteness a peculiar pearl-like transparency and brilliancy. Superadded to the sallow complexion and to the brilliant anæmic eye, are the irregular blotches or stains of a dark brown on the upper lip, on the forehead, and scattered in smaller spots on the cheeks. Her

skin is fine and delicate, and that of the face irritable, so that she is unable to use soap.

She soon falls into a state of debility from over-exertion or other depressing cause; the debility is accompanied with nausea and sickness, and sometimes with severe nervous headaches, which are relieved by sickness. The action of the kidneys is natural, perhaps somewhat deficient in amount of secretion; and she has a slight tendency to swelling of the ankles. Her tongue is soft and pallid; the bowels sluggish and irregular; and she suffers from languor and lassitude; but soon picks up her strength in the bracing climate of Scotland. Her circulation is natural; her hands and feet habitually warm; but there is a slight *bruit* in the action of the valves of the heart. She has had no rheumatism.

She gives the following account of the occurrence of the present affection. She had been travelling for four days over frozen snow, and the jolting was so severe and continuous as to produce a sickness resembling seasickness in one of the party. She was excessively fatigued by this journey; and, having two further days of exertion to go through, was, finally, thoroughly exhausted. She experienced nausea, sickness, and a feeling as though her liver were disordered; there was a yellowish tinge in her skin, and an orange colour of the urine, which induced her to apprehend an attack of jaundice. Suddenly, after these symptoms had continued for about a fortnight, she was surprised at perceiving that which she thought at the time to be a smudge of dirt upon her upper lip. It appeared, she believed, in the course of the night, and has remained until the present time, upwards of twelve months, varying a little in depth of colour with her health—being lighter when she is feeling well, and darker when out of health; but exhibiting no tendency to disappear.

The eruption of the *epheles* on her face, she thought, relieved the symptoms of general disorder under which she had been labouring; the nausea and sickness subsided; and she felt that the attack was gradually passing away.

Such is the history of a curious disorder, associated with *anæmia*; and of a nature difficult to remove, because of its dependence upon those obscure causes of mal-assimilation and malinnervation, which keep up the *anæmia*, now that the original causes have ceased. It was a question whether a long course of bromide of potassium, prescribed for the uterine affection, could have been the cause of the discoloration. I have no hesitation in saying, no, it was not; for similar cases are constantly occurring in which no bromide of potassium has been exhibited. Some, having in mind Dr. Addison's cases, have thought that the suprarenal capsules might be concerned. There is no good reason for believing that they are; although it is not unlikely that there may be some morbid action present in the solar plexus, or those of its filaments that preside especially over assimilation and healthy sanguification.

In the course of treatment which this lady has undergone for her complaint, she took two minims of Fowler's solution of arsenic three times a day for six months, and has latterly commenced the use of Donovan's solution. I stopped the latter remedy, believing that her digestive functions were not sufficiently established in power to enable her to derive advantage from arsenical medicines, and put her upon a course of general tonics, beginning with nitromuriatic acid and a mild bitter. Locally, I prescribed a stimulant plan of treatment.

**CASE II. *Melanæmia; Ephelis Frontis; Melasma Diffusa; Nervous Prostration.*** A lady, aged 34, unmarried, is the subject of *epheles frontis*, of two years duration. Her eye is *anæmic* and brilliant (*melanæmia*); she is thin, dyspeptic, nervous, and subject to depression of spirits. She complains of feeling ill, but without being able to define her illness.

She says that she had an attack of small-pox five years back; that she kept her bed for three weeks; up to this time she was stout and fat, but that since this illness she has been gradually getting thinner and weaker.

Two years ago she was much alarmed by a fire, which occurred in the house in which she was living; she stood for some hours on the wet pavement, without shoes or stockings, and exerted herself a good deal.

When all was over, her strength gave way, she felt thoroughly prostrated, and has been highly nervous ever since. It was after recovering from this shock that she first perceived the dark brown stains on her forehead, which have continued ever since, being sometimes lighter and sometimes darker in their hue. She first noticed them in the course of the supraorbital nerves, where, at present, they form two triangular patches, which spread upwards to the band of hair which covers the temples; and, at the upper part of the forehead, the apices of the triangles are connected by a transverse bar.

Her uterine functions are regular, and there is no trace of visceral disease; but she is impressed with the belief that her liver is out of order.

**CASE III. *Melanæmia: Ephelis Frontis et Faciei; Trifling Constitutional Disturbance.*** A lady, aged 35, the mother of two children, has *epheles* on the forehead and face. She reports herself as enjoying good health, and only seeks for the removal of the discoloured stains which mar her beauty. She is thin, somewhat sallow, and has a brilliant melanæmic eye. Her digestion is not strong, and she sometimes has fits of depression of spirits. Her habits are active; she is naturally energetic, but for some time past has lost her usual determination and courage. Nine months back she fractured her leg while hunting; but the stains on the face have been in existence for two years.

**CASE IV. *Leucanæmia; Ephelis Frontis; Origin in Nervous Shock.*** A lady, aged about 40, unmarried, has *epheles* of the forehead; the discoloration is most marked on the temples, in the course of the supraorbital nerves, and across the upper part of the forehead. The stains made their appearance eight years back, after severe affliction; and she first perceived the disorder in the form of two narrow bands, which followed the direction of the trunks of the supraorbital nerves.

She is thin, nervous, subject to pains in the head when her liver is out of order, and dyspepsia; but considers that she enjoys a fair average health. Her eye is somewhat *anæmic* (*leucanæmia*); and the mucous membrane of the tongue pale; she is also troubled with occasional attacks of palpitations of the heart, which are obviously nervous, as there is nothing abnormal in the sounds or action of the heart in the interval of the attacks.

**CASE V. *Melanæmia; Fuscado Cutis; Ephelis Crurum; Deranged Nervous Functions.*** A lady, unmarried, enjoyed good health up to the age of twenty; she was plump and strong and cheerful. At this time she had a love-disappointment, and became depressed and weak. She was then attacked with neuralgic odontalgia, which recurred three or four times a year for a period of four years. Her next misfortune was the sudden and painful death of a sister; she was stunned by the shock, and, for two or three months afterwards, unable to sleep. She describes her waking sensations to have been as though a plate of iron clasped her head; as though she were a statue; and as though she were benumbed and dead.

She is now thirty-six years of age. The skin of her face has a brownish or dirty yellow hue (*fuscado cutis*); her eyes are bright, but heavy; the conjunctivæ have a dusky whiteness; the edges of the eyelids are pale, as are her lips and tongue. She is depressed in spirits, and haunted with the idea of having about her some

loathsome disease, which she fancies every one she meets must detect. This disease, she believes, produces swelling of her nose and wrinkles upon the eyelids and around the eyes. She has two or three circular spots of ephelis on the legs. Menstruation is regular, but deficient both in quantity of excretion and colour; the latter is brown, and sometimes pale.

The history of this poor lady's case seems to point to the shock which overpowered her nervous system sixteen years back, and from which she has never recovered, as the primary origin of her illness. The first effect of the shock upon the nervous system was neuralgia; then the shock was repeated, with the consequence of loss of sleep and a general feeling of lifelessness and torpor; and following on this, at a later period, defective hæmatisis and anæmia, with the presence of black pigment in the blood—melanæmia. The melanæmia, which is not strongly defined, has engendered a muddy discoloration of the skin of the face and several small patches of ephelis on the legs.

CASE VI. *Melanæmia; Melasma Palpebrarum; Alopecia Areata*. A gentleman, a lithographic artist, aged 45, consulted me for alopecia areata, of which he had several circular patches on the scalp. He suffers from dyspepsia, has a pale tongue, is languid and weak, and depressed in spirits, but without regarding himself as ill. His visit to me had reference, as I have already stated, to alopecia areata, and not to any derangement of general health. His complexion is dark; but the most striking feature of his face is a well-marked melanæmic eye, with a dark discoloration of the integument of the eyelids, which adds to the brilliancy of the abnormal eye.

When I directed his attention to the colour of the eye and of the integument around it, he called it a "flat darkness" and "flat shadow"—technical terms belonging to his own profession, which express very truthfully this appearance of the eye. He moreover remarked, that he never succeeded in getting the expression of his eye in photography, in consequence of this peculiarity. He said that it was regarded by his family as an indication of his state of health, being deepest when he was weak and unwell, and less apparent after change of air and when he felt better in physical strength. It also increased when he had an attack of dyspepsia.

He is unable to assign a cause for, or a period of origin of, this melanopathic discoloration; and he has no patches of dyschroma on any part of the body. Four years back he met with a frightful accident—a fall—which crushed his forearm. This accident produced a severe shock to his nervous system; he was insensible and suffered from vomiting at the time, and for some months afterwards experienced considerable nervous irritability. The attacks of dyspepsia have been more severe since this accident.

The alopecia areata showed itself suddenly, as is commonly the case with this disorder, about four months back.

CASE VII. *Melanæmia; Melasma; Alphosis; Stearrhæa Capitis; Alopecia Asthenica*. A gentleman, aged 48, late a military officer, applied to me for a stearrhæa flavescens of the scalp; and at the same time complained of dyspepsia, nervousness, and sleeplessness.

Observing that he possessed a strongly marked melanæmic eye, which was brilliant and white with a transparent tint of blackness, but without any alteration of colour of the integument of the eyelids, my first question to him was: "Have you any dark blotches about your skin?" His answer: "No; but I have some white patches;" and he immediately proceeded to show me a patch of alphosis in the submaxillary region, in which, besides the achroma of the skin, the hair growing on the patch was white. Further: on examining his body, the skin of the abdomen was found mottled with melasma and alphosis. In the hypochondriac and inguinal re-

gions were two large and irregular patches of alphosis, and several of small size on the scrotum. The deep brown tint of the abdomen, increasing in blackness around the white patches, he regarded as his natural colour; but I had no difficulty in proving to him that neither the dark nor the light skin were normal, but that both were extremely exaggerated; and, in one or two smaller patches, the skin preserved its natural tint of brown, while that which surrounded them had an abnormal tint of blackness. It will be remembered that he made no complaint to me of the melanopathia and the leucopathia, and would not have mentioned them but for my inquiry, founded on a diagnosis of dyschroma; such diagnosis being suggested by that remarkable abnormal phenomenon, the melanæmic or melasmic eye.

This gentleman was obviously anæmic; and the brilliant, deep, liquid eye contrasted strangely with the pale, yellow, muddy, and ill-nourished skin of the face and scalp. There were other symptoms betokening a deep-seated malassimilation; his tongue was pale, and circulation languid; but there was nothing to lead to the suspicion of organic disease. He told me that the leucopathia and melanopathia had followed an attack of small-pox which he had had more than twenty years before; but that the affection of the scalp (stearrhæa flavescens), for which he consulted me, was only of four or five weeks standing; that, like a preceding attack, it had come on with dyspepsia; that the dyspepsia had resulted from a "moral shock"; and that the dyspepsia was accompanied with a wretched feeling of "misery and despondency".

CASE VIII. *Leucanæmia; Ephelis Faciei; Extreme Nervous Depression*. A lady, aged 40, is the subject of ephelis, dispersed in patches of a dirty black colour upon the forehead, face, and neck, down to the level of the clavicles. The stains have existed for about two years. Her complexion is pallid and bloated; the eye pale, bright, and watery (leucanæmia); she is weak, languid, and extremely depressed in spirits; her appetite is bad, and digestion deranged. She is a native of the West Indies, and has visited London to see the International Exhibition; but she hardly feels that she has energy enough to go there; her sole desire and constant want is to return home by the first mail.

I endeavoured in vain to obtain some distraction for this poor lady, and I succeeded in detaining her a week only. Upon my frequent inquiry as to the cause of her restlessness and misery, she gave me a very inadequate one—the want of success of a relative. Her case was a marked illustration of the mental and nervous prostration that so frequently accompanies the anæmia associated with melasma—melanæmia.

CASE IX. *Ephelis Dorsi Manus; Exhaustion of Nervous Powers from Overgrowth of the Body; Dyspepsia; Deep-seated Neuralgia of the Lower Limbs*. A gentleman, aged 38, very tall and thin, is the subject of ephelis fusca of the backs of the hands and in the popliteal regions. He complains also of severe neuralgic pains in the legs. He suffers from dyspepsia; has a melanæmic eye; his complexion is swarthy; he feels weak, and he is easily exhausted by exertion. These symptoms appear to be the consequence of nervous debility induced by overgrowth of the body; and, although growth has now ceased for some years, the powers of the system, and especially of the nerves, have not as yet been recovered. There is nothing to excite suspicion of an organic lesion.

KING'S COLLEGE HOSPITAL. In consequence of Mr. Bowman's retirement from King's College Hospital, some beds were transferred into other hands. The six which fell to the share of Mr. Fergusson and Mr. Partridge, were by them liberally placed at the disposal of the two assistant-surgeons, Mr. Wood and Mr. Smith.

## CASES OF IMPERFORATE BOWEL.

By HENRY DUNCALFE, Esq., West Bromwich.

*[Read before the Midland Medical Society, Birmingham.]*

DURING a period of twelve years, five cases of abnormal states of the colon and rectum have been brought under my notice, and these cases illustrate three varieties of imperforate bowel. In two instances, the external opening was closed; in two, the bowel ended in a *cul-de-sac* an inch or more above the anus; and in the remaining case the bowel was not discovered.

The affliction in any of its forms is rare, and it is a curious fact that all these cases occurred in my own practice out of about 3,000 births, whilst Dr. Collins observed only one instance in 16,654 children born in the Dublin Lying-in Hospital, and Dr. Zohrer of Vienna records two cases out of 50,000 new-born children. It may, however, be true, as suggested by Dr. West, that many instances of simple closure of the anus may have passed unrecorded, whilst all the instances of more serious malformation have been described.

In two cases, where the obstruction was situated at the orifice of the anus, the conditions were pointed out to me by the nurses, who noticed the defect when the children were first washed. In both those cases I waited till the collection of meconium caused the parts to be distended, and I then made a crucial incision, snipping off the angles afterwards. These cases gave no further trouble. I directed the round end of an ordinary "dip" candle to be passed into the bowel night and morning, and the children recovered without any other treatment.

The following case, though more interesting, is less satisfactory in its results.

A lady residing near my house, was attended by the late Mr. W. of Birmingham. The child, a male, was healthy and well nourished. I was called in on the third day after its birth. The friends became anxious, as the infant had not voided any stool, whilst the stomach rejected both food and castor oil, which had been administered according to instructions given by Mr. W. I visited the child in the forenoon; it appeared to be in a state of constant discomfort; vomited frequently, and made continued violent straining efforts to defæcate. I passed a soap suppository into the rectum, which was immediately returned with a little mucus tinged with blood; then, having oiled my finger, I passed it into the rectum and found that the bowel terminated in a pouch. I communicated the fact to the friends, and Mr. W. met me in consultation in the evening of the same day. He recommended an opiate mixture to be administered and the operation delayed till the pouch should become distended, and then for a trocar and cannula to be passed through the projecting part. Of course the symptoms of strangulated bowel continued, and with increased severity. The stomach and bowels were distended, and the child made a continual moaning cry, except when interrupted by vomiting and retching. The following day, Mr. W. again saw the little sufferer, and again postponed any operative proceeding, alleging that such cases usually terminated fatally, and the lower the bowel descended, the greater hope there would be of success. On the fifth day, I passed a trocar into the projecting bowel; some thick meconium passed, and water was injected through the cannula to favour the discharge; very little relief was given by this operation. The symptoms continued as before, the child getting perceptibly weaker. After the cannula was withdrawn no more meconium passed, and the child lingered on for forty-eight hours, when death happily removed it from further suffering. An examination was allowed after death. The rectum was perfect and the colon ended in a blind pouch. The trocar had passed through the centre of the membrane, but the collection of the meconium above pre-

vented any escape through so small an aperture. With all respect to Mrs. W.'s great experience and sound judgment, there can be no doubt but that we fall into two errors in the treatment of this case. In the first, blinded by the belief that the lower the bowel was protruded the greater hope there would be, the child was permitted to sink into that feeble state, that had the operation been successful, I am convinced the child would not have rallied; indeed, the bowel from distention, had become so paralysed, that very feeble expulsive efforts were made at the time of the operation, though previously very violent strainings had tended very much to exhaust the little patient. In the second place, the opening by means of the trocar, was a useless operation. Even the water injected through the cannula did not return, and though Mr. W. tried to coax down the meconium by passing a long probe into the bowel, very little indeed escaped. The pressure of such a quantity of thick fluid would, of course, prevent any escape, and a bottle filled with any thick fluid having a narrow neck, will clearly demonstrate how useless was that operation.

The existence of an anus and rectum, although a decidedly favourable feature, does not warrant quite so hopeful a prognosis as might at first sight seem apparent; but after those cases where the anus is merely covered by integument, these must offer the second best chance of recovery. The operation usually advised in these cases is to introduce a narrow straight bistoury upon the forefinger of the left hand, or upon a director through the closing membrane, and the opening thus made enlarged with the button-ended bistoury. It seems to me, though I have never performed the operation, that, simple as it reads, it will in practice be difficult. The gut is not so resistant as to be cut easily with a bistoury, and the finger becoming covered with the slimy meconium must lose a great deal of that sensitiveness which is necessary to guide the knife; then the expanded part of the rectum may be hit upon, and the bistoury passed behind the bowel into the pelvis. The pharyngotome and trocar are also advised by some medical writers. I have already stated my reasons why I would not use the trocar.

A case similar in every respect to the one I have just recorded, occurred in my practice in the year 1859. I adopted an operation different from any I had read or heard of, and I had the satisfaction of seeing the child live till the bowel acted perfectly, and the operation proved a success. The child died some time afterwards from pneumonia, followed by abscesses in different parts of the body.

I delivered a dissenting minister's lady of her fourth child on October 4th, 1859, and the following day my attention was directed to the child's having refused food and the breast, whilst vomiting and hicough had been noticed at times since its birth. Having found the anus perfect, I ordered a teaspoonful of castor oil to be administered. I was told the next morning that the oil was returned as soon as swallowed, and that there had been no evacuation. She still moaned as if in pain, but the face was not indicative of distress. Vomiting occurred now and then, chiefly when the child strained. Having oiled my forefinger I passed it into the rectum, and at about an inch or inch and a half, I found the bowel terminating in a pouch.

Remembering the fatal termination of a similar case which presented itself some years previously, I determined that this child should not die from exhaustion before the operation, and with the help of an assistant I performed the following operation with great ease. Seizing a slightly curved needle (armed with a double ligature) with a pair of forceps, I passed it up to the protruding bowel, and guided by the index finger of the left hand, thrust it through the centre of the pouch, withdrawing it by the forceps. My assistant then drew down the ligature, whilst I introduced a pair of sharp pointed scissors up the rectum; the pouch being put

on the stretch and steadied by the traction of the ligature. I separated the blades of the scissors and pushed them through the gut, then by closing the handles I made a good opening into the fore part of the bowel. I slipped my finger into the opening, and changing my scissors for button ended ones, I snipped through the tight edges, the ligature being gently pulled down during the whole time. By this means I opened two thirds of the closed bowel, and the posterior flap was brought through the sphincter. I passed a suture through it to the verge of the anus, and on withdrawing my finger a quantity of meconium was expelled by the straining efforts of the child. An India-rubber bottle full of warm water was injected and returned by the child's efforts, and soon afterwards the little patient fell asleep. I passed up a candle bougie twice daily for three or four days, and about the fifth day I took out the stitch from the bowel and snipped off the flap at a distance higher than the ligature, which I had left protruding through the anus. I do not know whether there would have been any risk of the bowel receding had it not been confined by the suture, but it gave no trouble after its removal. A warm water injection was given daily; the bowels acted well, and the child lived long enough to have the bowels brought into the normal condition. I should certainly adopt the same treatment in a similar state. The ligature answers several purposes; it draws down the pouch, it tightens the membrane so that the bowel does not recede before the scissors, and after the incision has been made, it makes tense the edges and permits the opening to be enlarged with ease and safety.

I have related these cases in succession, as the abnormal condition was so much alike in both, but the following case occurred about June 1856, between the two cases cited. The parents were innkeepers, and after the child had been born a few hours, the attendant noticed that no stool passed, though the child made some straining efforts. On examination, it was found that the anus was closed. I waited over two days, and as there was no protrusion or resistance when the finger was pressed against the perinæum, I advised an exploratory incision. This I did with my lancet to the extent of half an inch, and passed my finger through the wound, hoping to come into contact with the globular distended bowel, but I failed to discover any fulness or anything indicating the presence of the lower bowel. I allowed the case to go on for a day or two longer, and I then advised Amussat's operation in the left loin to relieve the child's suffering. Either from absence of the descending colon, or from the incorrect performance of this operation, I did not succeed in finding the bowel, and I closed the wound without being able to give the child the relief I had hoped for. The parents would not allow a *post mortem* inspection, and I can only mention this as a case where the bowel was defective for some distance from the anus.

### RARE CASES IN MIDWIFERY.

By EDWARD COPEMAN, M.D., Physician to the Norfolk and Norwich Hospital.

[Continued from page 664 of last volume.]

CASE XXII. *Cerebral Affection after Labour.* I was summoned in the middle of the night on September 16th, a distance of eighteen miles, to Mrs. — (who had been confined about ten days) in consequence of a severe attack of illness after labour, with a threatening of puerperal convulsions. She was of middle age, and the mother of several children, one, if not more, born in China, where she had once suffered from cerebral disturbance, subdued at length by large doses of opium; of which drug she was said to be at the time so tolerant that not less than five or six grains produced any effect. The night before I saw her, she had been suddenly seized with pain in the

head, intolerance of light and noise, and confusion of mind, so that she scarcely knew where she was, and believed herself to be dying. She was very faint, and when her surgeon arrived, he ordered turpentine in drachm doses, several of which had been taken before I got there, and from which she expressed the greatest comfort, saying she felt at once that it would save her life. Before taking it, her pulse was 140. I found it a little under 100; and hearing she had been unable to sleep for several nights, I advised a full opiate enema. The lochia had not stopped, neither were there any decided uterine symptoms; but I considered that her brain, naturally susceptible, had become irritable and exhausted from want of sleep.

The enema produced a very good effect, being followed by seven hours' sleep; and a few days afterwards I was informed that all was going on perfectly well.

Her husband told me she made a very good recovery.

CASE XXIII. *Puerperal Disease.* I was summoned to a distance, late on the evening of Saturday, October 4th, to visit a delicate lady, about 35 years of age, and mother of a large family, coming in rapid succession. She had been confined ten or twelve days, and there was some difficulty with the placenta. There was no distinct history of a chill, but the nurse said the lochial discharge had been offensive for a day or two, and paler than it ought to have been, but this was only mentioned after putting the question to her. I found her very much depressed, with rapid pulse, confused sensorium, and great loss of power, both nervous and muscular; and yet there were no decided uterine or abdominal symptoms. However, we applied turpentine stupes to the abdomen as a precaution, washed out the vagina, gave a strong opiate enema to quiet the nervous system and procure sleep; and prescribed frequent small doses of quinine and chloric æther, with wine and good nourishment to support her strength.

I did not see the patient again, but have since been informed by her surgeon, that after a rather severe struggle, she ultimately recovered. She could not take the quinine, but continued the chloric æther, and turpentine stupes. After my visit, she exhibited more decided puerperal symptoms; her body becoming prominent, her mind more disturbed; she had no sleep but what was produced by medicine, and thirty or forty minim doses of chlorodyne answered the purpose well. The turpentine greatly relieved the tympanitic condition of the abdomen; but after this had subsided, she was attacked with phlegmasia dolens. In spite of this complication, however, the result was favourable, and the patient is now downstairs and resuming her family duties.

CASE XXIV. *Puerperal Disease: Fatal.* Mrs. —, aged 28 years, a delicate lady and very deaf, had been confined about a fortnight, when I was called to see her on October 1st. The history given me was as follows. Before her confinement she had an attack of bronchitis, which much reduced her strength; her labour soon followed, and the placenta required artificial removal on account of hæmorrhage, which for the moment was severe, and made her very faint. She went on pretty well for a day or two, and then had an attack of pleuro-pneumonia of the left side, accompanied by very acute pain, and relieved by antimony, blistering, calomel and opium etc. When this gave way to treatment, she complained of slight abdominal pain, the abdomen was found to be tumid, and there was commencing phlegmasia dolens in the right leg. The secretion of milk had ceased, and the lochia had changed colour. These latter symptoms made their appearance two days before I saw her; and I found her in a very serious condition, suffering from most threatening puerperal mischief, which had been masked by the more acute disease in the chest, and for a day or two escaped observation. Her pulse was 140 or more, and her respiration hurried and whistling. The sensorium was not much disturbed, but on dozing she

felt rather confused. The chest-affection was apparently cured. The abdomen was not tender, but very tympanitic and conical; and I discovered uterine tenderness on deep pressure above the right groin. She had no sickness nor diarrhœa. The lochia were muco-purulent and very offensive: and the nurse told me she had noticed the bad smell four or five days, but had not mentioned it. Muscular power was at a very low ebb, and her general condition most unfavourable. Turpentine was applied to the abdomen this morning, and we now gave her a drachm dose internally; we also enveloped the whole limb affected by phlegmasia dolens, the right leg, in moist flannel sprinkled with turpentine; an application which I have found of much more service in that disease than any other treatment whatever. All other medicines were discontinued; frequent vaginal washings ordered, and a turpentine enema the next morning, should there be no relief from the bowels; the turpentine to be also repeated internally twice in the night, and mild nourishment administered. I left her at 8 P.M., without a hope of recovery from such a frightful complication of illness, the only circumstances at all in her favour being that her manner was not very unfavourable, and her brain but little disturbed.

On the 2nd, her surgeon sent me the following report: "I have seen Mrs. — this morning. She has had a restless night, bowels very much relaxed, tympanitis not so much, mind quite intact, pulse not so quick. She expresses herself as unable to take any more turpentine, but we go on with the external application. I have given her a chalk mixture with a little opium, catechu, cascarilla, and chloric æther. It is a very bad case, yet there are some favourable symptoms. It is remarkable how during the chest-affection, this disease was masked; in fact, there appeared no symptoms of such until the other was removed."

On the 4th, I heard she was still alive, and in some respects better. The body was much less swelled; the diarrhœa was stopped; the leg not painful; but her pulse was still rapid and she was very weak.

On the 6th, I received a letter requesting another consultation, but stating that in many respects the patient had been going on favourably. On my arrival in the afternoon, I was told a serious change had taken place in the morning, and she was fast sinking. I found her quite sensible, without pain either in the abdomen or leg, and with scarcely any swelling in either. But she was so exhausted and feeble, and her pulse small and very rapid, with a corresponding frequency of respiration, that it was clear she must die. However, she lingered on without any other symptoms than extreme exhaustion until the 9th, and then quietly sank.

[To be continued.]

DEATH OF A SURGEON FROM AN OVERDOSE OF PRUSSIC ACID. The following particulars are from the *Waterford Mail*:—"We regret to have to announce the sudden and premature death of Joseph Sawyers, Esq., surgeon of the 8th Regiment, which occurred on Friday evening. Mr. Sawyers had been in the habit of taking small doses of prussic acid, and on Friday evening he felt unwell, and mentioned to his servant that he would not go to dinner; the servant laid a bottle containing prussic acid and one containing essence of peppermint on the table, and it is surmised that he took the prussic acid in mistake. A coroner's inquest was held on Saturday, and a verdict was found that the death was caused by an overdose of prussic acid. The remains were interred with military honours, at the Abbey Church, this (Monday) morning, and were accompanied by all the officers—some having come from a considerable distance to pay this mark of respect to their deceased comrade, who was much beloved and is sincerely regretted by them."

SATURDAY, JANUARY 10TH, 1863.

### SCIENCE AT HOME AND ABROAD.

THE truth of the old adage, that no man is a prophet in his own country, is very strikingly exemplified by the manner in which we in this country are too apt to treat the contributions to science of foreigners, and the contributions of our own countrymen. We have more than once taken occasion to call attention to this act of unpatriotic partiality; and, in fact, have recommended those of our scientific workers, who wish their observations to be duly appreciated by their own countrymen, to have them transferred into a foreign dress, and brought out, in the first instance, in a foreign country, under a foreign name. We verily believe that the translation "from the German," for example, into English of such productions would ensure for them a far better chance of attentive and serious consideration than they would obtain if their British authors had produced them originally in their mother tongue and country.

Our remarks have called forth the following pertinent observations from the pen of one of our most accomplished scientific observers:—

"English observations are not epitomised in the same way as foreign, and the result is, that a most erroneous impression exists amongst practitioners, viz., that the scientific work performed in this country is exceedingly small, and bears no comparison, either in quantity or quality, with that produced on the continent. Sometimes papers seem to be selected for translation in consequence of the number of letters in their authors' names—sometimes, because the author boldly reiterates statements, the truth of which was disproved half a century ago. Thus, recently, we have had the subject of spontaneous generation re-opened, and the most unsatisfactory experiments of certain French observers reported at some length. If these gentlemen still remain uninfluenced by the multitude of facts which have for years been accumulating against their pet theory, it seems scarcely desirable to encumber English journals with their dogmatic assertions. There are, and probably there will always be, people who will maintain that living beings result from the accidental approximation of certain inanimate particles to each other, but it is surely unnecessary to give very wide publicity to such untenable vagaries.

"There is just now a fashion in this country of giving very undue prominence to the work of foreigners, while that of our own countrymen is underrated. Foreigners are themselves surprised at the sort of articles which are sometimes translated into English journals.

We desire in these, as in other matters, to treat foreign observers with the utmost generosity and liberality; but we cannot conceive that any good can result from this mode of discouraging the younger men of our profession in this country, who, under difficulties of which foreigners have no conception, are trying their best to advance medical knowledge. We have seen on several occasions indications of a desire on the part of some who have, perhaps by accident rather than by real work of their own, attained influential positions, to make the utmost of foreign work, and almost to ignore that of their energetic juniors. It seems to us but natural, that men occupying high positions, but who are no longer engaged in scientific labours, should encourage in every possible way the advances of their juniors; but we fear that the generosity and encouragement, which would certainly produce valuable fruit if dispensed on this side the channel, too often assumes the miserable form of patronage on the other. The only result is disappointment here and a considerable amount of contempt and ridicule there. Individuals in high position ought to know that a man may allow himself to accept the patronage but laugh at his patron. We trust, however, that the younger men in this country, who are now contributing so much to the real advance of many departments of science, will continue their labours with earnestness, and that their ranks will be recruited and their cause strengthened until the merits of British science are acknowledged by Englishmen, when those whose duty it is to satisfy the scientific craving of the members of our profession will soon make the discovery that scientific work is being carried on here as well as in France or Germany, and that the British medical public takes as much interest in that which is done by their countrymen as by foreigners."

#### GRATUITOUS MEDICAL SERVICES.

A STRIKING illustration of the correctness of the views concerning the abuses of London hospitals so often referred to in this JOURNAL, may be found in a letter in the *Times* of the 1st of this month. A writer calls upon the benevolent to give their alms to a London hospital which has done acts of mercy to our Commissionaires. The voice comes from the barracks of the commissionaires, and is the voice of gratitude for services received. It details the immense good done by the hospital, its £7000 spent *per annum*, its 1400 in-patients, and its 38,000 out-patients *per annum*. It then goes on to make the following instructive statement:—

"As some people may wish to know how far we carry out our principles of 'self-help,' I may state that our sick-fund contributions for the present year are about £20—a rate which, if equalled by all other patients, would increase the income of the hospital by nearly £3000."

From this we find that these commissionaires actually pay £20 towards the funds of the hospital. Now, is it not clear that, of these 38,000 out-patients, a very large portion must be of a class who receive wages as large as and much larger than these commissionaires? If this be the case, why should this business of charity be carried on to this lamentable extent, after such indiscriminate fashion, demoralising the working classes, and unfairly taxing the benevolence of the benevolent? Why! if these 38,000 patients come from the neighbourhood of the hospital, we must conclude that the whole sick of the parish pass through the doors of the hospital during the year!

We seriously again ask the profession, must there not be something radically defective in a charitable system which throws (at one single hospital) 38,000 patients on the hands of the medical men during one year, for the reception from them of gratuitous medical services? Must there not be something radically defective in a charitable system, which is ever crying out, in the most imploring terms, for money and help, notwithstanding the gift of their immense services by the medical profession? The medical profession, it appears, gives its gratuitous advice to 38,000 patients (at one single hospital, be it remembered); and so deeply does a discriminating public appreciate the value of the golden and gratuitous advice (medical and surgical)—of these immense services—that it will scarcely furnish the obolus required for the purchase of physic for sick and bandages for the wounded. How long our profession consent to play a part in this gross of suicidal injustice?

#### TYPHUS IN LANCASHIRE.

WE have now unfortunately the best authority for saying, that the scourge which ever follows in the track of war, misery, and famine, is now claiming its victims in the manufacturing districts. Protracted low diet—sufficient to sustain life, but not sufficient for vigorous life—is beginning to tell its tale upon the bodies of the working classes there. Our profession has, as usual, been prodigal of its money and its services in this terrible conjuncture; but never more than now is it able to do great service by enforcing upon the public at large the all-important fact—that it is not by physic, but by food only, that this plague can be stayed; and, what is of still greater importance, its attacks anticipated. The profession should, therefore, urge the necessity of still great and greater exertions being made in this work of charity; for here comes the scourge, typhus fever, whose steps can only be arrested by the outpourings of public benevolence.

"Dr. Buchanan," we read, "physician to the London Fever Hospital, and one of the London Medical Officers

of Health, has been engaged, since the middle of October, in an official inquiry into the sanitary condition of the principal manufacturing towns under their present exceptional circumstances. He has reported the results of his observations from day to day to the Privy Council Office, and has now presented a summary of his experience in the places he has visited, embodied in a document of painful interest.

"This medical report, unhappily, leaves no doubt that 'one of the most lamentable consequences of extreme destitution has made its appearance.' Typhus fever has broken out among the population of Lancashire for the first time since 1847. It has appeared in the track of want, of which Dr. Buchanan well says it is the 'steady follower.' In Preston and Manchester, typhus fever has now assumed an epidemic form. In Preston, there were 227 cases between Midsummer and the end of November; and those attacked died at the rate of 23 per cent. In Manchester, there have been 100 cases of the disease in the same period, with nearly the same high rate of mortality among its victims.

"The existence of this disease, remarks Dr. Buchanan, 'by itself suggests doubts as to the complete success of the measures that have been adopted for the relief of the distress.' In twelve of the chief manufacturing towns, including Manchester, Preston, Stockport, and Bolton, the following external signs have been noticed among the population, and they all indicate a readiness to sink under the first attack of disease:—Among the cotton-workers, as a body, there is an evident loss of strength, colour, and flesh. There is a wan and haggard look about the people that is not habitual to them. Medical men assert that the parents have lost their health in a much greater degree than the children, and of the parents the mothers suffer most. Between the permanent paupers of the Manchester Union and the recently hiring workmen of Ancoats the experienced medical eye can now draw no distinction in the apparent ability of the two classes to resist disease. From the whole of the report it is evident that, while the cases of death from actual want have been very few, there exists an immense amount of what may be termed mild starvation. It is the impending, gradual deterioration of the tary condition of the people that is now the great danger. Privation will make itself more and more felt every week of its continuance. The allowance that is not sufficient now will be less so as the cold of the winter sharpens. Warmth now becomes a necessity of life, only second to food. To secure it the poor will always sacrifice many of the conditions of health. They close doors and windows, and paper up the fireplaces, to exclude every draught of air. The report notices this want of ventilation as of itself a dangerous source of disease."

### THE PATHOLOGY OF TERTIARY SYPHILIS.

TERTIARY syphilis (writes M. Diday) must not be considered as one of the stages of evolution of a disease. It is a distinct pathological condition, distinguished from secondary syphilis by its clinical character, its prognosis, and its treatment.

Secondary syphilis may be produced at will—excepting the case of immunity due to previous syphilis; its radical cure is its ordinary termination; and its lesions are contagious.

But tertiary syphilis cannot be produced at will; nor can its accession be anticipated; spite of all remedies, it is a persistent disease; and its lesions are not contagious.

Comparing these two groups of characters, we find that those of secondary syphilis belong to the class of virulent affections, or poisoning by morbid secretion; whilst those of tertiary syphilis belong to the class of diathetic diseases.

Tertiary syphilis is, in fact, syphilis-poisoning which has passed into the stage of diathesis; from being essentially transitory, it has become essentially permanent.

To what cause is this transformation (which does not occur in all cases) due?

It is certainly not due to long duration of the secondary stage of syphilis. Secondary lesions may last for three or four years, and yet produce not tertiary syphilis.

Neither is it due to the neglect of any specific treatment; for observation shows us that tertiary syphilis arises as often whether specifics have been used or omitted.

The true agent of tertiarism is doubtless the varying degree of power of the virus; and above all the varying degree of resistance offered by the system to its action. Persons of weak vitality, or who are enfeebled by age, or dyscrasie, etc., are they in whom the syphilis becomes tertiary and permanent.

Experience, as shown by the powerlessness of medicine, confirms these views. Mercury almost invariably fails; iodine, an admirable palliative, is only a palliative. To cure a diathesis, a radical and permanent change of food, of residence, of profession even, in a word, of all social and moral habits, are required. Hereby alone can we hope to obtain a cure. This is what few patients can be made to understand; and why, therefore, the radical cure of tertiary syphilis is so rare.

### THE WEEK.

MR. BOND, a sporting gentleman, some years since, endeavoured to persuade the Jockey Club that the winners of great racing stakes should be called upon to give a small percentage of their winnings to hospitals. The Jockey Club would not, however, listen to this charitable proposal. Last year, Mr. Bond made another effort in the same direction. He promised to give 1000 guineas for the purposes indicated, if the winners of the Derby and Oaks would also each give 10 per cent. of their gains for the same. The 10 per cent. has not been forthcoming; nevertheless, Mr. Bond will not be balked of his benevolent purpose. He, therefore, gives his 1000 guineas to be divided amongst the following hospitals; namely, 100 guineas each to the Westminster, King's College, St. Mary's, the Cancer, the London, and St. George's Hospitals; to the Royal Free Hospital, £157:10; and for the establishment of a drinking-fountain in St. Clement's Danes, £316.

It will seem surprising to the profession, that at this far advanced day of chemical and sanitary science and scientific agriculture, a proposal should have been made, by the engineer of the Metropolitan Board of Works, to discharge the sewage of the Western division of the metropolis into the Thames, above London—at Cremorne. The metropolitan medical officers of health have, we are glad to see, taken up the subject and entered their protest against it. Of course, the Board of Works has but one grand object in view, viz., to get rid of the sewage. It has nothing to do with a polluted river, or with sanitary or agricultural science. Its business is simply to collect and discharge the sewage out of a given district. The duty, therefore, of determining where and how the sewage shall be discharged out of the district naturally falls upon others. Indeed, after all that has been said and done in reference to this pollution of our rivers by sewage, it does seem surprising that the engineer should have ventured to make such a proposal. That it will be defeated by the vigilance of the Metropolitan Health Officers we doubt not for a moment. Certainly, it is no business of these gentlemen to say how the sewage should be otherwise disposed of. It is for the engineer to overcome engineering difficulties. Of this, however, we may be very sure: let the public only insist that under no circumstances shall sewage be discharged into rivers, and plenty of schemes will be found for its disposal otherwise. Incidentally, also, this prohibition will act as an immense benefit to the community; for it will, naturally, lead to the utilisation of all the riches of sewage, and thus be the means of returning to the soil the essence and virtue which is won from it in the shape of food.

DR. LEE of Philadelphia, who is now visiting the different medical institutions of England and the Continent, makes the following comparison between English, French, and American lunatic asylums.

"I have also visited the most noted institutions of this kind in England and France; and, with the exception of the agricultural colony at Clermont, I have seen nothing deserving of special commendation which is not also found in our own country. Indeed, I think, as a general rule, we are considerably in advance of the old world in the successful treatment of the insane; and our statistics will show a larger percentage of cures than can be found in the large majority of European asylums. And it is very natural that it should be so. Americans are the most practical people in the world; they are not easily led to adopt novelties merely because they are novelties, but which have nothing else to recommend them; but they speedily introduce every improvement which is founded in reason and common sense, and which promises any practical benefits, wherever it may have originated. The unreasonable and obstinate prejudice which exists in Great Britain against adopting anything new from foreign countries, fortunately does not exist among us; and hence we are never found lagging far behind in the race of improvement and the march of civilisation. Hence Professor Acland, M.D., of Oxford, who accompanied the Prince of Wales

in his recent visit to the United States, expressed surprise that American physicians should visit Europe to examine lunatic asylums, for they would find better ones at home, as at Philadelphia, under the charge of Dr. Kirkbride (and, I may also add, at Bloomingdale, under the charge of Dr. Brown), than can be found in Europe. Such I know to be the opinion of the most enlightened physicians of England, Germany, and France, who have made themselves acquainted, by personal observation, with such institutions on both sides of the Atlantic. In England I visited, among others, the great establishments of Hanwell, Colney Hatch, Bethlehem Hospital, etc.; also the private asylums of Dr. Conolly and others; but I saw nothing which is not well known and carried out in the United States."

THE French Academy of Sciences has been more fortunate in the satisfactory disposal of its grand prize than the Academy of Medicine. The question proposed for the grand prize in the physical sciences was, "The Comparative Anatomy of the Nervous System of Fishes". No worthy competitor appeared; but 1,500 *francs* were allotted to MM. Philipeaux and Vulpian for the treatise entitled "Researches for the Determination of the Parts which constitute the Encephalon in Fishes". The first prize (1,800 *francs*) in experimental physiology was accorded to M. Balbiani for his treatise on the Sexual Phenomena of the Infusoria; and the second to MM. Chauveau and Marey, for the Study of the Cardiac Circulation. The prizes in medicine and surgery were distributed as follows:—To M. Cruveilhier, 2,500 *francs*, for his works on Pathological Anatomy; to M. Lebert of Breslau, 2,000 *francs*, for his treatise on Micrography; to M. Frerichs of Berlin, 2,000 *francs*, for his treatise on Diseases of the Liver; to M. Larcher, honourable mention and 1,500 *francs*, for his work on Normal Hypertrophy of the Heart during Pregnancy; to M. Cohn the same, for his work called "Clinical History of Embolic Affections, studied from a Practical Point of View". MM. Dolbeau and Luys also touch 800 *francs* and an honourable mention—the first for his work on Epispadias, and the second for his work on the Structure of the Brain properly so called. MM. Ollier, Fousnangrè, and Bourgeois, get only a simple mention. The prize Alhumbert—"To endeavour, by well-conducted Experiments, to throw new Light on the Question of Generation called Spontaneous"—was accorded to M. Pasteur. Another prize Alhumbert—"The Experimental Study of the Modifications which may be determined by External Agents in the Development of a Vertebral Animal"—was divided between MM. Lereboullet and Dareste. To M. Barallier, who has demonstrated the non-identity of typhus and typhoid fever, 2,000 *francs*. (Some of our readers will, we suspect, question this adjudication.) M. Cass received the Barbier prize for his works on Glycerine. The following are the prize-questions proposed by this body for the next year's meeting:—Natural Philosophy: On the Comparative Anatomy of the

Nervous System of Fish (3,000 *francs*, Sept. 1st, 1864). To study the Changes effected during Germination in the Constitution of the Tissues of the Embryo and Perisperm (3,300 *francs*, April 1st, 1864). On the Production of Hybrid Animals by Means of Artificial Fecundation (3,300 *francs*, Sept. 31st, 1863).—Medicine: To trace the History of Pellagra (5,000 *francs*, April 1st, 1864).—Medicine and Surgery: On the Application of Electricity to Therapeutics (5,000 *francs*, April 1st, 1866).—Surgery: On the Preservation of Members by Preserving the Periosteum (the Academy offers 10,000 *francs*, the Emperor also 10,000 *francs*, April 1st, 1866).—Bordin Prizes of 3,000 *francs* each, to be sent in before December 31st, 1863: On the Distribution of the Vessels of the Latex in the Organs of Plants. On the Anatomical History of Coral and other Zoophytes of the same Family. On the Structure of the Stems of Plants, with a View to determine their respective Families.

THE following testimonial to the value of "Lane's Indian Remedy for Small-pox" is worthy attention at the present moment.

"INDIAN REMEDY IN SMALL-POX. Eruptive Fever General Hospital, Kalorama, Washington, D.C., November 26th, 1862. Surgeon-General W. A. Hammond, Washington, D.C.:—Sir,—Acting in accordance with instructions received from the Surgeon-General's Office to test the efficacy of 'Lane's Indian Remedy for Small-pox', and report thereon, I have the honour to state that I have used the box of 'remedy' in the treatment of cases of small-pox in this hospital; and in no case, used either as a gargle, eye-wash, or internal remedy, have I been able to detect any effect produced upon the patient or the disease, except that in one case the patient, after taking it several days in succession, complained of its producing nausea. In every other case I have found it inert, and as useless as I should expect a decoction of sawdust to be, administered in similar cases. Your, etc., R. J. THOMAS, Act. Assist.-Surgeon U.S.A., in charge."

TARTUFFE has commenced the present as he finished his last journalist year, with abuse flung at the British Medical Association and its JOURNAL. We are always anxious that our readers should be fully apprised of these exacerbations of his, because they are the most certain certificates and testimonials to the successful progress of our Association which we could lay before them. That Tartuffe should be excessively violent at the present moment is explicable enough to us. At this season of the year, the demonstration of our success is painfully impressed upon our adversary's senses by the unanswerable logic of figures. Here is the last diatribe of the *Lancet*, under the head of the Fever Controversy, couched in its usual elegant diction, and drawn from its ordinary sources of truth and honesty:—

"This has attracted attention, and has produced a literary *bévue* of errors and improprieties, in which some of our medical contemporaries have distinguished themselves by more than ordinary incapacity and rashness. The unhappy organ of the British Medical Association

seized eagerly the opportunity of distinguishing itself by a terrific onslaught on Dr. Tweedie. Of course, that experienced physician had explanations to offer, and next week the fierce attack was followed by an abject apology. If possible, the apology was more dangerous than the attack, for it is more full of errors, and this week the JOURNAL must again eat humble pie."

All we will remark upon this performance of Mr. Tartuffe's is, that, true to the specific characters of his prototype, he has not the courage to express any opinion of his own on the subject of this Fever Controversy. Here, as on so many other occasions when moral courage is required for the delivery of an honest opinion, he quietly turns tail, and suggests a reference to arbitration—falling foul-mouthed on those whose literary honesty he has not the courage to imitate. We will add that, we trust, and would willingly believe for the credit of our cloth, that the conductors and instigators of these unseemly attacks of the *Lancet* are not members of the medical profession.

AN interesting point of medical ethics is undergoing a warm discussion amongst our French friends. The question is, what ought a doctor to do if consulted about the physical eligibility for marriage of one of his patients? Two societies have had their say upon it, and have concluded: "That the medical men should abstain from giving any information respecting the health of a client on the occasion of his or her marriage." This view of the case is not, however, accepted by the press, which declares, on the other side, that in its opinion: "Circumstances may occur in which the medical man is bound, both by honour and morality, to enlighten families as to the state of their patient's health." It strikes us that this is just one of those questions, about which learned men like to discourse and make difficulties, but which practically has never been a source of serious difficulty to anyone.

Dr. Sichel, the oculist, describes, in *L'Union Médicale*, a peculiar kind of senile delirium, of a non-febrile character, which he has observed seven or eight times, after extraction of cataract in old people. He attributes it solely to the occlusion of the eyes consequent to the operation. Some of his patients might have suffered from commencing delirium tremens; but others again had been most abstemious all their lives. The patients get up in the night, walk about, gesticulate, tear off the bandages, insult and menace those about them, etc., and so as to require restraint. He relates a case in which all the symptoms of delirium disappeared when the bandage over the eyes was removed. He has never observed it in persons under sixty years of age; nor in any cases except those in which the operation for cataract was practised by extraction.

The number of inscriptions at the School of Medicine and Pharmacy at Bordeaux for the ensuing session is 102.

## CONSERVATIVE MEDICINE.

Dr. FLINT, Professor of Medicine in the Bellevue Hospital Medical College, New York, makes the following remarks in the *American Medical Monthly* :—

"The meaning of *conservative surgery* is well understood. The conservative surgeon aims to preserve the integrity of the body. He spares diseased or wounded members whenever there are good grounds for believing that by skilful management they may be saved. He resorts to mutilations only when they are clearly necessary. He weighs carefully the dangers of operations, so as not to incur too much risk of shortening life by resorting to the scalpel. By conservative medicine, I mean an analogous line of conduct in the management of maladies which are not surgical. The conservative physician shrinks from employing potential remedies whenever there are good grounds for believing that diseases will pursue a favourable course without active interference. He resorts to therapeutical measures which must be hurtful if not useful, only when they are clearly indicated. During the last quarter of a century a change has taken place in medical sentiment as regards surgical operations. New and grand achievements in surgery seemed formerly to be the leading objects of personal ambition. Boldness in the use of the knife was the trait in the character of the surgeon which was most highly admired. It was customary to speak of them as brilliant, and the daring surgeon enjoyed somewhat of the *éclat* which belongs to the hero of the battle-field. This analogy was implied when one of the greatest of our American surgeons, wishing to distinguish his most brilliant exploit, styled it his Waterloo operation. The change that has taken place is marked. What would once have been considered as a degree of courage to be admired, is now stigmatised as rashness. It is an equivocal compliment to say of a practitioner that he is a bold surgeon.

"An analogous change within the same period has taken place in medical practice. Formerly, boldness was a distinction coveted by the medical as well as by the surgical practitioner. "Heroic practice" was a favourite expression, consisting in the employment of powerful remedies, or in pushing them to an enormous extent. The physician emulated the surgeon in daring. The change is not less marked in medicine than in surgery. We hear now oftener of diseases managed with little or no medication, than of cases illustrating the abuse of remedies. We desire to preserve the vital forces, to avoid the perturbations and damaging effects of potential therapeutical agencies.

"Physicians have acted on the presumption that most diseases do not pursue a favourable course without treatment more or less efficient. This has been, to a still greater extent, the popular belief. The apparent proof of the success of the Hahnemannian treatment rests on this belief. What are the facts already ascertained with respect to the intrinsic tendencies of different diseases? Take, as examples, pneumonia limited to a single lobe, and acute pleurisy. It is sufficiently settled that these diseases involve very little danger in themselves, proving fatal only in consequence of complications. The practitioner, therefore, no longer feels obliged to employ blood-letting, mercurialisation, cathartics, blisters, etc., in these diseases, with reference to the saving of life. The only question is, do patients pass through these diseases as well without as with such measures of treatment?

"Our acquaintance with the natural history of the great majority of diseases is as yet very incomplete. We cannot conscientiously withhold remedies which we have reason to believe may prove useful. Cases are therefore

to be slowly accumulated in which, from circumstances not under our control, diseases have been uninfluenced by therapeutical interference. This knowledge, it is evident, is the true point of departure for the study of the effects of remedies as regards the termination and duration of diseases. The information already obtained has rendered the use of powerful therapeutical agencies far less common than they were a few years since.

"In defining conservative medicine, we have seen that it expresses a characteristic of the improvements in medical practice during the last twenty-five years.

"If we turn from remedial measures to dietetics, we find that the improvement which has taken place in practice contributes to the illustration of conservative medicine. In fact, conservatism is, perhaps, not less conspicuous in the contrast as respects the diet of the sick than in any other point of view. In cases of fever and all acute diseases, twenty-five years ago, it was generally deemed an essential part of the treatment to withhold alimentary supplies. In chronic affections, too, the diet was usually much restricted. Physicians seemed to lose sight of the plain fact that the vital powers must languish in proportion as the alimentary supplies fall below the wants of the system, and that death may be produced by starvation in disease as well as in health. At the present time, a nutritious diet is considered as highly important in the management of fevers, as well as in diseases which tend to destroy life by exhaustion, and most physicians appreciate the importance of keeping the body well nourished in chronic affections.

"Clinical experience has rendered it doubtful whether the antiphlogistic treatment exerts much effect on the intensity of inflammation, its results, or its duration. Conservatism, therefore, dictates a careful weighing of the evils of the treatment against the chances of its usefulness as regards these objects."

## DR. STOKES ON EPIDEMICS.

IN his introductory address at Meath Hospital, Dr. Stokes says :—

"What is it that causes an epidemic is one of the most difficult of questions. Why, in the pressure of an epidemic, one man sickens while another escapes—why essential maladies observe laws of periodicity, we cannot tell—why locality affects their general characters and organic results is yet unexplained—nor why, on the other hand, after travelling their tens of thousands of miles, destroying their victims under the most varied conditions of climate, soil, food, temperature, they yet preserve much, if not all, of the original character—remains an open question. Many discussions have arisen on this point, and a fierce controversy has raged between the contagionists and non-contagionists. The advocates on both sides can bring forward plenty of isolated facts in support of their theories; but the argument from isolated cases is of little value. That there is an origin for epidemic disease, besides contagion, is self-evident; that it is propagated by contact is another question. I have been in the habit of referring to the mode of settling this matter. It was to compute against the occurrence of a certain circumstance—namely, if there was no such thing as contagion. My father, when Professor of the Practice of Medicine in the Royal College of Surgeons, directed his attention very much to the subject of contagion. He was a strong advocate of the doctrine of contagion. Perhaps he went too far in his belief in the exclusiveness of the doctrine of contagion. He thought that in looking at the general circumstances which attended the spread of an epidemic in this country, the probabilities for or against the doctrine of contagion

might be submitted to calculation. One of his most intimate friends was the late celebrated Dr. Brinkley, Bishop of Cloyne, who was at one time the Astronomer Royal of Ireland. He was admittedly one of the very first mathematicians of his day, and was especially skilled in that difficult part of mathematical investigation, the doctrine of chances. Now, in the progress of an epidemic in Ireland, in a family of twelve persons, the disease has been known to attack eleven out of the twelve. In some cases the passing of the fever through so large a proportion as eleven individuals out of twelve has taken a very considerable period of time, as you may readily understand. It has taken about three months to go through them all. Now, my father proposed these two problems to the Bishop of Cloyne for solution:—“An epidemic prevails so severely that one person out of seven sinks. A family of twelve is selected in a particular district before the epidemic has visited it. What is the chance that eleven out of the family shall take the disease, supposing the sickness of one of the family does not promote the sickening of another—that is, supposing the disease not to be contagious, and supposing the family to be not unusually liable to the disease?” The answer furnished by Dr. Brinkley is, that the probability against such an event is 189,600,000 to 1. That is a very singular and extraordinary result. The whole subject is yet to be worked out. It is interesting to observe that Humboldt, in his *Cosmos*, speaking of epidemic diseases, says that their origin and nature is among the most difficult of problems, and he suggests that some light may be thrown on the matter, when the laws of terrestrial magnetism are fully determined. What we do know of these mysterious phenomena may be thus stated:—That although having certain characteristics which are common to all, they exhibit marked and special differences. Thus the plague differs from cholera, cholera from typhus, and so on. That they are in a greater or less degree propagated by contagion. That epidemics of the same disease have not always the same characters. That their mortality is greater on their first outbreak in any locality. That they travel over vast distances, and although they may arise in warm latitudes they preserve their characters in cold ones; the cholera of Central India and of St. Petersburg was the same disease. That their advent and disappearance are often sudden. That they are not symptomatic of any known anatomical change, but they often induce local diseases which are secondary to the general malady. That their symptoms are, to a great degree, under the laws of periodicity. That, as far as we know, the disease is not to be met by any specific cure. That, as yet, all explanations of their origin are insufficient or obviously erroneous. Lastly, that anatomy only throws a negative light upon their nature, telling us rather what they are not than what they are. The plague of the Levant, which has preserved its character since the time of Thucydides; the black death; the sweating sickness; the typhus and yellow fevers, and the Asiatic cholera—in a word, the great causes of the wholesale destruction of man, act by some influence not yet discovered even by microscopic anatomy; so that we come to the strange conclusion that the diseases most fatal to man are those least connected with organic change which, when it is met with, is secondary, inconstant, and insufficient to explain their symptoms. Such is the present state of our knowledge.”

**IMPERIAL COURT DOCTORS.** The following is the position assigned by high etiquette to the French court doctors on great state *levée* occasions:—In the Salon of Apollo, a crowd of inferior officers of the various households, not on duty, with the physicians and surgeons, ordinary and extraordinary, consulting and non-consulting of the Imperial family.

## Association Intelligence.

### NOTICE REGARDING NEW MEMBERS.

By desire of the Committee of Council, the General Secretary requests that the Local Secretaries will be good enough to forward to him the names of all New Members who join the Association through the Branches; as otherwise the JOURNAL cannot be sent to them.

PHILIP H. WILLIAMS, M.D., *General Secretary.*

Worcester, November 10th, 1862.

### LANCASHIRE AND CHESHIRE BRANCH.

#### REGISTRATION OF DISEASE.

SIR,—In the letter sent to you last week, I omitted to enclose a form for the return of new cases of disease, coming, each week, under the care of those gentlemen who should consent to help forward our scheme for the Registration of Disease. I beg now to supply a form, which may serve as a specimen of what would be required. The disease-list is made as short as possible, so that the trouble of filling it up may be very light; but it has been judged sufficient for our purpose. We should, however, be glad to receive suggestions from any of your readers.

I am, etc.,

ARTHUR RANSOME.

1, St. Peter's Square, Manchester, Dec. 31st, 1862.

..... District.

Return of new cases of disease, coming under treatment in your public practice, during the week ending Saturday, the      day of      , 186      , at      .

	Diseases.	Deaths.	Remarks.

Signature, .....

**THE LYONS HOTEL DIEU.** The great civil hospital, *Hôtel Dieu*, is the oldest hospital in France, having been founded in the sixth century, by Childebert, son of king Clovis. It contains twelve hundred beds, mostly free; there are 150 patients who pay 25 cents per day, (1 f. 25c.) There are nine surgeons and physicians, besides a large number of internes connected with it. The nursing is done by a society numbering one hundred and fifty *hospital sisters*, so-called, aided by a band of *hospital brothers*. The building fronts on the Quai du Rhone, and extends 1,055 feet. It is crowned with a magnificent dome, built in 1737, but not completed till 1842. In one part of the building are rooms for a secondary school of medicine and pharmacy, which is here carried on. There is a similar dome situated in the middle of four spacious wards, constructed of a Grecian cruciform shape, and under the centre of it is an octagonal altar, visible to all the patients in the wards. The front is ornamented with statues of Childebert and his wife Ultrogothe, also of the Rhone and Saone, the arms of the village, etc. This hospital appears to be admirably conducted, is clean and well ventilated. (*Dr. Lee of Philadelphia.*)

# Special Correspondence.

## LIVERPOOL.

[FROM OUR OWN CORRESPONDENT.]

IN the course of last month, the first of the proposed quarterly meetings of the Lancashire and Cheshire Branch of the Association was held in the board-room of the Chester Infirmary, when, considering the present busy season and the short days, the attendance was good, especially of members from a distance. In the unavoidable absence of the President, the chair was taken by Dr. Callon, one of the Vice-Presidents of the Branch. The proceedings at these meetings are to be limited to the reading of papers, and on this occasion were initiated by Dr. Waters of Chester, who gave a succinct and graphic sketch of two cases of Volvulus successfully treated by the Tobacco-clyster. The first case was that of a gentleman, aged 36, in perfect health and of temperate habits, who, in lifting a heavy stone, suddenly felt a peculiar sensation, as if something had given way internally, which was followed by constipation and vomiting, and the ordinary symptoms of obstruction of the bowels. When first seen by Dr. Waters, the symptoms had continued for four days, unrelieved by the judicious and cautious use of leeches, fomentations, castor-oil, the warm bath, enemata, and other remedies. The patient had a very anxious look; the tongue was clean; pulse 80. He complained of a twisting pain in the bowels, and a constant desire to go to stool. There was slight soreness a little below the umbilicus on the right side, but no general abdominal tenderness nor intolerance of pressure. An infusion, made with half an ounce of tobacco, was given by the rectum, which produced decided syncope, vomiting, cold perspirations, and feeble pulse, and was followed by a speedy action of the bowels and the complete recovery of the patient.

The other case was that of a dairymaid, who, in the act of churning, overreached herself, and suffered in a similar way; the constipation continued for three days, and was at once relieved by the tobacco-clyster.

Dr. Waters observed, that he was induced to bring forward these instances of the successful use of tobacco, chiefly because, although much had been lately written in the JOURNAL on the subject of obstruction of the bowels, no allusion whatever had been made to this remedy. He strongly urged the importance of resorting to the tobacco sufficiently early, instead of postponing it, as was sometimes done, until the patient was moribund, or, if it happened to be a case of *intussusceptio*, until the invaginated intestine had become adherent. He thought it desirable, as a guide to the treatment, in cases of this kind, to endeavour to arrive at a definite conclusion as to the cause of the obstruction; and although it was often confessedly difficult, if not impossible, to determine this point during life, still he considered in many instances, of which these two cases were examples, a tolerably certain conclusion might be formed. When the constipation was not preceded by diarrhoea, but came on suddenly after violent exertion, and was unaccompanied by symptoms of peritonitis or enteritis, it

might be assumed that it was caused by a simple twist of the bowel, and treated accordingly.

In the brief discussion which followed, Dr. Waters of Liverpool, referring to the extreme interest connected with the subject of obstruction of the bowels, indicated the following as important points to be kept in view in the treatment of these cases; viz., to avoid purgatives, to give opium in the early stages, and a fair trial of simple copious enemata. These failing, he would certainly resort to the tobacco, as recommended by his namesake, the author of the paper; or perhaps to belladonna, as an allied remedy, and one which would probably cause less severe depression, and of the success of which he had heard a most favourable report given from an eminent London physician; but he had no experience of its use in his own practice. Dr. Williams of Wrexham said he had seen the tobacco clyster successfully used, some years ago, in several cases in the wards of the institution in which they were now assembled; and he could particularly call to mind two instances in which a strangulated hernia was reduced under its influence.

The revival of the use of the tobacco enema, if it should really follow this favourable and encouraging report of its employment, would be a curious illustration of the tendency in medical, as in other matters, to move in cycles; for those of us who can look back some quarter of a century will remember that this mode of treatment was then regarded as one of the expedients to be adopted as a matter of course in cases of intestinal obstruction, and especially in strangulated hernia; but which fell into disuse from the supposed uncertainty of its action, and from the alarming and even fatal results which occasionally followed its administration.

The next paper, entitled Facts and Observations in Obstetrics, was read by Dr. Watson of Chester, and in it he dwelt strongly upon the extreme value of "fresh air and pure water as aids in the management of the parturient process"; and expressed his belief that the importance of these natural remedies had not hitherto been adequately appreciated; and to this he attributed a large amount of the mortality which occurs in childbed. This was followed by the exhibition of a specimen of Thoracic Aneurism by Dr. Wilkinson of Manchester, which was taken from the body of a patient under his care in the Manchester Infirmary. There was some uncertainty as to the precise origin of the aneurism. Dr. Wilkinson described it as arising from the upper part of the arch of the aorta, between the origins of the left carotid and the *arteria innominata*; both of those vessels becoming implicated in the gradual enlargement of the sac. Dr. Roberts, however, was inclined to view this as an instance of abnormal distribution, described by Quain as of frequent occurrence, in which the carotid and *arteria innominata* arose from the aorta by a short common trunk, from which he believed the tumour had taken its origin. In the specimen now shown, the tumour had pressed upon the left carotid, obliterating that vessel; and also upon the pneumogastric nerve of the corresponding side, so as almost entirely to destroy its continuity: this had given rise to gangrene of the left lung, which was the immediate cause of death. The history and symptoms corresponded with those usually

observed in thoracic aneurism. Some interesting and important observations were made by Dr. Roberts on the use of iodide of potassium in aneurism. In several cases, some under his own observation, and others which had been reported to him, the administration of the iodide in full doses, commencing with five grains up to twenty grains three times a day, had been followed by very striking and beneficial effects upon the aneurismal tumour itself, as well as upon the general symptoms. The bulging and impulse were sensibly diminished, and the sac in some cases became more or less solidified; while the pain, dyspnoea, and general distress and suffering of the patients, were materially relieved. Without venturing to generalise from a limited number of cases, he thought, after all he had heard and observed, that this mode of treatment was deserving of a further trial.

A short paper, of much practical interest, was then read by Dr. Nevins of Liverpool, on the Treatment of Ascites and Anasarca, in which he illustrated, by the relation of three or four cases of ascites followed by recovery, the advantage of resorting to tapping or acupuncture respectively, in the treatment of these two forms of dropsy, in a much earlier stage of these affections than is ordinarily practised. As I believe the paper will shortly be published *in extenso* in the JOURNAL, it is not necessary to enter into further particulars here. This concluded the business of the meeting; and the members present, about twenty-five in number, dined together at the Albion Hotel.

Since the foregoing report was written, a case has occurred which deserves notice, especially in connection with the subject of volvulus, with which it may be said to have some affinity. A gentleman aged 36, a member of our own profession, tall and stout, inclining to corpulency, and of previous good health, having gone to bed quite well, after a hard day's work and eating a hearty meal, was seized with severe epigastric pain and violent vomiting, accompanied with constipation and considerable distension of the abdomen. These symptoms were relieved by opium, rest, and purgatives; and in a few days he was considered convalescent. But, on the subsidence of the abdominal distension, there was detected a large, firm, well-defined tumour, below the epigastrium, the nature of which could not be ascertained with certainty; but the impression on the minds of his medical attendants was that it was a case of impaction of feces in the colon, and the treatment was directed in accordance with that view. Purgatives and injections never failed to bring away copious solid evacuations, free from scybala or hardened feces; and for some time the patient seemed to be progressing favourably, the tumour apparently becoming diminished in size. In about a fortnight from the first seizure, vomiting returned with increased violence, and continued more or less constantly for the subsequent two weeks, during which, in spite of stimulants in large quantities and all other suitable means, he became delirious, and sank. A *post mortem* examination revealed the following somewhat unusual pathological condition. A large tumour as big as two fists, composed of cheesy, scrofulous deposit, was found resting upon and arising from

the anterior surface of the mesentery. It appeared to have been originally hard, and to have undergone softening from recent inflammation. There were only slight traces of recent peritonitis; but the intestines were in many places glued together by old adhesions, and in some parts their calibre was greatly diminished by the unnatural twists and turns given to the bowels by their agglutination. The case appears to have been one of chronic tubercular peritonitis, differing, however, from the usual course of that disease so graphically described by Dr. Barron, chiefly from the circumstance that the tubercular deposit, instead of being generally diffused throughout the peritoneum, was accumulated in one large solid mass. The cause of death appeared to be exhaustion consequent upon excessive vomiting and constitutional irritation.

Before leaving this subject, I cannot refrain from mentioning a case which happened many years ago in the practice of the celebrated Dr. Carson of this town, and which, so far as I know has not been published; but it is so instructive and interesting as to deserve to be rescued from oblivion. A man who was under treatment with a fracture of the lower extremity, and consequently confined in the supine position, suffered from obstinate constipation, a condition which, he told his attendant, had always occurred when he was kept on his back for any length of time. "Oh," said the surgeon, "we will soon put that to rights"; and to work they went with castor-oil injections, and the usual routine, but still the obstruction continued, and gradually passed through the usual phases of ileus, and the patient died. On opening the abdomen, a large, hard, moveable tumour was discovered, which, in the supine position, had pressed upon some portion of the intestinal canal, producing complete obstruction, which, it was evident, would have been easily removed by a change of position, if the condition could have been ascertained or guessed at during life.

Your readers, especially those unacquainted with the locality, will probably be surprised to learn that, notwithstanding the close proximity of Liverpool to the seat of the cotton famine, neither the social nor the sanitary condition of the town has, at present, to any appreciable extent, participated in the injurious consequences of that calamity. There is not more distress here than is usual at this season of the year; and although the death-rate of Liverpool, especially from zymotic diseases, has risen considerably above the average, chiefly from the prevalence of scarlatina, and from a remarkable increase of continued fever, neither of these epidemics can be referred to a state of unusual destitution; nor can they be traced to any special defect in the sanitary condition of the town; which is in the same state of efficiency which for several years past has kept down the zymotic death-rate below that of most other large towns in this country. From this it may, I think, be inferred that, although sanitary measures undoubtedly exert a powerful and vitally important influence over the progress and extension of zymotic diseases, still, in spite of every practicable precaution, these epidemics from time to time originate, and are propagated, under conditions, and in obedience to hidden laws, which our present state of knowledge does not enable us to explain.

The present epidemic of scarlatina here has prevailed amongst all classes, rich as well as poor. It has been to a considerable extent of a very grave type, putting on in the severer cases, especially in children, that formidable and rapidly fatal complication graphically described as "the bull neck"; but more scientifically known as diffuse indurated cellulitis of the throat. The milder cases have been more than usually prone to be followed by albuminuria and anasarca. Some interesting practical remarks on this epidemic have already appeared in your report of the proceedings of our Medical Institution; to which I must refer those who wish to pursue the subject.

As to the epidemic of continued fever, the prevailing type is typhus. I am informed by Dr. Gee, physician to the Fever Hospital, that of the cases admitted into that institution, typhus predominates over typhoid in the proportion of about ninety-six in one hundred cases, and that with regard to the general mortality, the age of the patient proves the principal modifying condition; those of a moderate age, neither very young nor very old, are the most likely to recover; the greatest number of deaths occurring in the extreme ages on either side.

The highly contagious nature of fever has been abundantly demonstrated during the present epidemic. Those who have had the opportunity of observing its progress, cannot fail to have noticed that close communication with infected persons is the cause to which the extension of the disease can be most frequently and most clearly traced. We have, I regret to say, witnessed a melancholy instance of this in the lamented death of Richard Yates Ackerley, Esq., a much and deservedly esteemed member of our profession, and I believe one of our oldest associates, who, in the full vigour of mature manhood, and in the active pursuit of his profession, was struck down by fever, and died in eight days, leaving a widow and young family to mourn his loss.

One of the Roman Catholic priests in attendance on the inmates of the Fever Hospital, has also fallen a victim to typhoid fever, contracted, no doubt, during the close personal intercourse with the sick, and especially with the dying, which characterises the religious ministrations of that church.

As a further proof of this view, we had the outbreak of fever brought into Liverpool by the crew of an Egyptian frigate, which your readers can scarcely have forgotten, and which might be further corroborated by recent facts which have come under my notice in the course of this visitation; but time and space are no longer available, and I must at once bring my communication to a close.

**SMALL-POX IN SUNDERLAND.** The report of the medical commissioner of the Privy Council to Sunderland, on the small-pox epidemic in that quarter, was read at a meeting of the board of guardians on Wednesday. It embodied statistics showing that while the disease had reached its greatest intensity in Sunderland during last quarter, it has been worse in Bishopwearmouth and Monkwearmouth during the quarter just elapsed. Everywhere, however, it seems to be now declining, though what the commissioner calls "epidemic influence" is still manifest. Vaccination of children, revaccination of adults, and general sanitary expedients are recommended in the report of Dr. Seaton.

## Reports of Societies.

### OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, DECEMBER 3RD, 1862.

W. TYLER SMITH, M.D., President, in the Chair.

TEN gentlemen were duly elected Fellows of the Society.

*A Case of Multiple Medullary Cancer, Complicated with Pregnancy.* By THOMAS TANNER, M.D. The patient was a woman, aged 39, five months advanced in her third pregnancy. In the abdominal parietes, just to the right of the umbilicus, there was a well defined tumour, of about the size of a large walnut. Adjoining the lower part of the ensiform cartilage of the sternum there was a more extensive mass, also seated in the abdominal wall. In the left groin there was likewise a flattened growth, about two inches and a half in diameter. On examining *per vaginam*, a very firm growth was discovered projecting into the canal, feeling as if it had its origin from the lower part of the sacrum, though in reality it was entirely seated in the recto-vaginal septum. The uterine souffle and the fetal heart could be plainly distinguished. The liver was much enlarged, and this enlargement, combined with the size of the uterus, occasioned a wearying feeling of distension, as well as some dyspnoea. The propriety of waiting and ultimately effecting delivery by the Cæsarean section was discussed; but such a plan of treatment was regarded as not applicable to the present instance. Consequently, on the 30th of July the membranes were punctured, and about half a pint of liquor amnii withdrawn. On August 1st, labour pains of fair severity set in; but the os uteri was so very rigid on the following afternoon, and as the patient was getting tired and exhausted, and moreover, as the mass of cancer in the recto-vaginal septum reached to within almost an inch of the pubes, it was evident that nothing could be gained by further delay. Dr. Tanner, therefore, slowly tried to dilate the os uteri; and this being partially effected, the fœtus was broken up with a pair of forceps, and removed piecemeal. No difficulty was experienced with the placenta; the discharge of blood was very slight; no injury was done to the uterus or vaginal walls; and the woman was left tolerably comfortable. For some few days she continued to progress favourably; but on August 10th a severe attack of diarrhœa set in, aphthæ formed on the tongue and gums, and for the first time in her life she became jaundiced; and, on the morning of August 26th, death took place from exhaustion.

At the autopsy, fourteen hours afterwards, the body was found greatly emaciated. In the abdominal parietes, to the right of the umbilicus, there was a deposit of firm medullary cancer of the size of a walnut, together with a larger growth just below the ensiform cartilage. The liver was enlarged to about three times its natural size, and studded with medullary masses, varying in size from a pea to a small orange. There was likewise several deposits of cancer in the great omentum, in the spleen, in the walls of the colon, and one large mass binding the sigmoid flexure of the colon to the tissues of the pelvis. In the pelvic cavity there was a separate deposit, extending chiefly down the recto-vaginal septum, and completely blocking up the vagina. The inguinal glands on both sides were enlarged and infiltrated with medullary cancer. The uterus, considering the time which had elapsed since delivery, was of its normal size, and healthy. At the apex of the left lung there was a small deposit of tubercle, which had undergone calcareous degeneration, while at the same part of the right lung there were several small tubercles. The heart was healthy, but its walls were flabby. The kidneys were healthy.

The paper concluded with observations as to the different modes of treatment which might be resorted to in such a case as that detailed, together with the reasons which led to the adoption of that practised.

*Retention of the Catamenia, for more than two years, in a Married Woman.* By WALTER CHAPMAN, Esq. The history of this case, prior to its coming under the care of the author, was reported as the *fifth* case of cure of vesico-vaginal fistula, in the *Lancet* of November 24th, 1860, by Mr. I. B. Brown. This lady, in her third confinement, was delivered with instruments of a still-born child, and soon afterwards was found to be the subject of a vesico-vaginal fistula. She was operated on twice, and was cured; the last operation being in the middle of June, 1860. This patient was first seen by Mr. Chapman on September 26th, 1862. She was sitting up, able to superintend her domestic affairs and walk about, and presented the aspect of health. She was robust, rather short, with a superabundance of fat, and 40 years old. She complained of great irritability of the bladder and stomach, and of severe pain in the lumbar and sacral regions. When she was in bed, on external examination of her abdomen, no difficulty was experienced in determining the existence of a large tumour, resembling the gravid uterus at about the sixth month. She had no reason for supposing herself to be pregnant, but said she had not menstruated since the operation. On a vaginal examination it was found that the cervix was lost in a general enlargement of the uterus, the mouth of which could not be detected. The speculum revealed the spot where the os uteri had existed, but it was now hermetically sealed. Mr. Chapman stated his opinion that the symptoms resulted from a retention of catamenia. Dr. Tyler Smith examined the patient, and confirmed the diagnosis. It was agreed that an opening should be made into the uterus for the evacuation of the fluid. This was done by the author, on October 5th (assisted by his friend Mr. T. Trent), by passing the index finger of the right hand through the spot which could be detected by the touch as having been the site of the os uteri. Its withdrawal was instantly followed by the escape of ten or twelve ounces of a treacly fluid, of a dark claret colour, perfectly free from any unpleasant odour; and much more gradually flowed away. She was kept in bed, but became very ill on the third day, the symptoms resembling those of peritonitis. From this attack she appeared to recover, and went on tolerably well for some days; but on the morning of October 16th, after a night of sickness, she became prostrated, and died at two p.m. No *post mortem* inspection could be obtained.

Mr. OWEN thought that the cause of death might be attributed to the admission of air into the uterus, in its relaxed and enlarged condition. After the gravid uterus is emptied of the fetus and secundines it immediately contracts to nearly its natural size; but here that reaction was not likely to follow, whilst the daily injection of water which had been employed exposed the organ afresh to contact with the air through the artificial opening, which latter presented no obstruction like that of the os and cervix uteri.

Dr. GRALY HEWITT remarked that the chief question to be determined was the cause of the fatal result in this interesting case. He considered that it was probably due, as suggested by Mr. Owen, to *præmia*. At the last meeting of the Society, he had alluded to the occasional circumstance of a fatal result following the evacuation of the uterine contents in cases of menstrual retention by subsequent passage of some of the blood into the peritoneal cavity. The explanation of this curious circumstance he had then attempted he still thought the most probable one, and that it was due to the contractions of the uterus becoming more forcible as its bulk diminished. However that might be, it did not seem that in the case now before the Society any such occur-

rence had taken place. He considered that the best course to adopt in treating such cases would be to make a minute opening, and to allow the fluid to escape as it had collected—gradually; further, that it was decidedly expedient to avoid anything, such as the use of injections of water into the uterus, likely to be the means of conveying air into the cavity of that organ.

*Case of Monstrosity.* By A. MEADOWS, M.D. The two lower extremities were absent, and a caudal appendage about four inches long was substituted; the body, gradually tapering off, ended in this pointed process; there were no external genital organs, and no anus. Dissection showed that the bowel ended abruptly at the sigmoid flexure of the colon. There were no kidneys or bladder, nor any trace whatever of any urinary apparatus. The suprarenal capsules were present, and were of large size, but there was very little proper structure in them, being chiefly two membranous sacs. An ovary and a somewhat convoluted Fallopian tube lay on either side of the pelvis, but there was no trace of a uterus or vagina. The liver, spleen, and other abdominal organs were normal, as were all the thoracic viscera.

Mr. SQUIRE noticed the absence of the kidneys as of more interest than the external deformity. That intra-uterine life and growth should go on to the degree here seen without those organs was very remarkable, especially as they are not inactive during the fetal state, as was shown by the occurrence of concretions of uric acid in the kidneys before birth; and he related the case of a still-born male child that he had had the opportunity of examining, where the calyces and pelvis of the kidneys were filled with numerous uric-acid calculi, some of the size of small peas. The parents of the child were known to him; the father had been operated on for stone, and was then passing uric-acid calculi by the urethra. He was a continual sufferer from marked symptoms of the uric-acid diathesis.

Mr. OWEN, many years ago, delivered the wife of a respectable farmer in Essex of a well-formed female child, in which the os coccygis was prolonged into a caudal appendix about three or four inches in length, tapering off, and in every respect resembling the tail of an animal, being curled up on the back when at rest, and frequently moved in other directions. The mother attributed this growth to a strong impression made on her mind during pregnancy, for three or four months of which period she had fed a young pig, the beauty of whose tail she constantly admired. Mr. Owen, by the express desire of the mother, removed it by a ligature gradually tightened for a week. The child lived (but never walked without the aid of crutches) for nine years, when she died of hæmoptysis. The parents would not allow an examination. The tail, along with a minute description, was placed in the museum of Guy's Hospital by the late Mr. Bransby Cooper.

#### ON THE INFLUENCE OF THE MOTHER'S HEALTH IN THE PRODUCTION OF RICKETS.

By W. TILBURY FOX, M.D.

THE paper commenced with an analysis of the pathological changes in the rickety subject, from which it appears that the leading feature of the disease is simply a deficiency of lime-salt in the early nutrition of the child; and the object of the paper was to point out what appeared to be a tangible cause for such a deficiency—viz., the occurrence of menstruation during the greater period of lactation. A table of examples was given, as exhibiting the matter in its several details and aspects; and in most of the cases which came under the author's observation, it was noticed that whenever mothers had freely and repeatedly menstruated during lactation, the child was rickety, unless the latter had been artificially fed with food, (such as milk), and thus furnished with bone-forming material; and the degree of rachitis appeared to be in direct ratio to the amount and degree

(both as regards frequency and duration) of this condition, exceptional cases being accounted for in the fact of the mother not wholly suckling her infant. The *modus operandi* of the influence of menstruation upon the composition of the milk was discussed briefly, and though little is known upon the matter, yet it appeared, on comparing together the analyses of Simon on the one hand, and Becquerel and Vernois on the other, that the percentage of salts is much lessened in nurses who menstruate during lactation, and hence the child wholly fed upon the milk of the latter would probably become rachitic. The author thought it likely that rickets is produced in the majority of cases in this way. The paper then contained some remarks upon the use of certain kinds of food in very general use which conduced to the production or evolution of the disease—for example, Brown and Polson's, the Oswego, and the Maizena so-called corn flours, these being oftentimes merely starch, contrasting them with such as the semola of Bullock and Reynolds, which was rich in gluten or flesh-forming substance; and attention was drawn to a new preparation—the saccharated wheat-phosphates, which might take the place of sugar in the food of children, especially those who are rickety. In conclusion, the author stated that he had introduced the subject as a provocative, rather than as a certainty of opinion.

Dr. GRAILY HEWITT believed that there was a very general impression amongst the profession, and he thought also amongst the public at large, as to the inadvisability of allowing lactation and menstruation to go on in the same individual. The theory now propounded by Dr. Tilbury Fox would give an explanation as to the reasonableness of this impression. The subject was so novel that it would hardly be expected that the Fellows of the Society could properly discuss the paper so as to do it justice. Each must observe and collect facts on which to decide *pro* or *con*. in reference to the matter. He would ask Dr. Fox one question: How are those cases to be explained where children, the subjects of rickets, do often, after being apparently successfully treated, relapse long after any evil connected with lactation has ceased to be in operation? Such relapses were, he had observed, by no means uncommon.

Dr. GERVIS wished to ask the author of the paper how, on his theory, the occurrence of rickets in children wholly brought up by hand, or in children whose mothers did *not* menstruate during lactation, was to be explained? The fact also of the children of mothers who menstruate during lactation in many cases certainly not proving rickety, would appear to militate against Dr. Fox's views. Dr. Gervis was inclined to consider that the occurrence of menstruation during lactation was not *par excellence* the cause of rickets, though possibly influential in its production just so far as it proved injurious to the mother's health.

Dr. Fox, in reply, begged the Society to remember that the matter had been brought before them, not because the observations were conclusive, but for the purpose of courting inquiry. The mode of causation pointed out was not the *sole* one; for, as Dr. Graily Hewitt had observed, rickets might ensue after the weaning of the child. In this case the disease was due to, or the tendency to it worked out by, the use of foods deficient in certain constituents. So far, however, as his (Dr. Fox's) observation went, it appeared that most rickety children belonged to mothers who had menstruated during lactation; and if the paper should appear in print, the Fellows would find in the list of cases instances of rickets affecting one member only of a family, all the concomitants of the rearing of the children being the same, with the exception that the mother menstruated regularly and freely when nursing the rickety child, and then only. In reference to Dr. Druitt's remarks, it might be observed that the leading pathologists held that all that is necessary to the production of rickets is a deficiency of lime;

and this conclusion seems inevitable if we glance at the intimate structure of the rickety bone, in which all the cellular components are fully developed, and in which the only unusual condition is an absence of calcareous matter. Dr. Gervis may possibly find in the exceptional cases mentioned by him, where children are not rickety, though nursed by mothers menstruating, that some such cause as artificial feeding explains the apparent contradiction. In reply to a question from the President, as to how rickets occurring during intra-uterine life could be accounted for, Dr. Fox remarked that the worst case he had met with was that of a child whose mother menstruated during pregnancy.

## WESTERN MEDICAL AND SURGICAL SOCIETY.

DECEMBER 19TH, 1862.

A. W. BARCLAY, M.D., in the Chair.

ON CONTINUED FEVER, AS IT HAS APPEARED IN ST. GEORGE'S HOSPITAL DURING THE LAST SEVEN MONTHS. BY EDWARD R. HARVEY, M.D.

THE author began by remarking that, since the time of Jenner, no better opportunity than the present outbreak of fever had occurred for studying its symptoms and treatment. What is fever? That no *rash* need accompany it was quite admitted, other organs manifesting its characteristics; and, as a disordered organ of the body might produce symptoms quite those of fever, great should be the care to examine those organs, otherwise a false report of the case is registered. The statistics of the Fever Hospital and of St. George's differed materially for the years 1855 and 1859. Could this be because an epidemic differs widely in different parts of the town? The *post mortem* book at St. George's showed that, from 1852 to 1861, the deaths from fever averaged 9 a year; 15 being the highest, 3 the lowest. In 1862, 16 had already died. The state of the intestines in these 16 cases had been thus: 4 cases were not examined; 3 of those that were examined had ulcerated bowels; 3 had patches of congestion, the glands being natural; 6 were healthy. One-fourth of those examined had ulcerated bowels: in the previous year it was 70 per cent. (not 25, as this year).

The symptoms of the patients of this year were the following. One of the three bodies with ulcerated intestines had no *skin-eruption*; 2 had rose-spots, going away on pressure; the 6 with healthy intestines had mulberry or measles eruption; of the 3 with patches of congestion, 2 had mulberry spots, and 1 only petechiæ. The distinction was clearly seen—mulberry eruption and healthy intestines, rose-spots and ulceration. As to the *bowels*: during life, ulceration and diarrhœa co-existed. Of those who died with ulcerated bowels, 2 had severe diarrhœa, 2 mild; in 7 the bowels were well open, in 1 costive. In the 8 cases of typhus fever, diarrhœa occurred this year both at St. George's and at the Fever Hospital, contrary to former experience. The *brain-symptoms* marked the distinction between typhus and typhoid; the mulberry eruptions always coexisted with delirium or stupor; the rose-spots and ulcerated bowels with restlessness, but no delirium.

Including the fatal ones, 58 cases of fever had been at St. George's Hospital during the last seven months; 9, or 15.5 per cent., had died, being less than 1 in 6. At the Fever Hospital, the average is about 1 in 5; whilst at St. George's during the last nine years, to the end of 1859, it has been 11.4 per cent. Of the 58 cases lately in St. George's, 41 had an eruption, 10 rose, and 31 mulberry or measles. Of those without eruption, 2 were cases of typhoid, 3 typhus, and the rest febricula. Thus there were of typhus 34 cases, of typhoid 12, and febricula 12. All the *typhoid* patients had confusion of thought, but no active delirium; 10 out of 12 had diarrhœa; and one-fourth of those who died had typhoid

fever. Of the typhus, in 5 the brain was clear; 11 were slightly delirious, and 18 severely so. The bowels were costive in 11, quiet in 10, relaxed in 8, and subject to diarrhoea in 5. Of the 58, 26 patients came from the neighbourhood of the hospital; 6 were affected in the hospital. In no case did a case of each type come from the same house. From May to December 1st, most cases were admitted in July, fewest in August.

The treatment, for the most part, had been simple; namely, to support the patient by beef-tea, wine, brandy, etc., as indicated, with opiate or astringent injection for the bowels, ice to the head, and opiates for the delirium, and for stupor a blister; in typhus, purgatives if needful, but with care.

Dr. Fuller's treatment differed from that of the other physicians. He gave an emetic at once, and a scruple of quinine every hour for three doses, wine and brandy if necessary; afterwards quinine, in two-grain doses every four hours. This treatment caused 6 out of 8 cases to be painfully affected by the quinine, as to deafness and more prostration; and in one case increased delirium. On an average, Dr. Fuller's patients mended on the ninth day; whilst those who had other treatment mended upon the seventh. Three of Dr. Fuller's cases were of a low, destitute class; two were assistant-nurses in the hospital; and the rest ordinary cases.

#### LIVERPOOL MEDICAL INSTITUTION.

DECEMBER 11, 1862.

JAMES HAKES, Esq., Vice-President, in the Chair.

*Imperforate Rectum Operated on with Success.* Mr. STEELE related the following case. A female child, three days old, was brought to him on November 21st; and on exploring the rectum by the little finger, it was found to terminate in a *cul-de-sac* about an inch above the anal orifice. Nothing could be felt to give any indication of the presence of the gut above. The parents were very anxious that something should be done; and Mr. Steele obtained the assistance of Mr. Bickersteth, who succeeded in passing a grooved probe, without force, a considerable distance upwards towards the abdomen, and made a cautious incision with a bistoury in the direction in which the rectum would, in its natural condition, extend. This was followed by pretty free arterial hæmorrhage, but no meconium appeared. No further incision was made, and the rectum was plugged, and a compress applied. The following morning, on removing the compress and plug, Mr. Steele was delighted and surprised to observe a slight oozing of meconium; this gradually increased; and from that time, the child continued to pass its motions freely, and appeared to have completely recovered. On the fourteenth day after the operation, the child was brought again, with the information that no evacuation had appeared for five days. By means of a director carefully introduced, the bowels were relieved of a copious fluid motion, and the child has gone on quite well since.

Mr. STEELE remarked that this case encouraged us to operate; and it also showed that the child ought to be watched for some time after the operation. These operations are not often successful; not one in ten recover. Another case he had had proved fatal.

Mr. HIGGINSON said it seemed desirable, when possible, to drag down the mucous membrane to the anal orifice, and fix it there.

Mr. STEELE explained that in this case it was not very near the orifice, but higher up the canal, that the malformation existed.

The CHAIRMAN said he had known a child live twelve or thirteen weeks with an imperforate anus.

*Placentæ of Triplets.* Dr. GRIMSDALE shewed a specimen of placentæ of triplets. All the three children are now alive. Two of them measured each eighteen inches in length, and the other seventeen, and they were strong

children. The placenta were by no means small; two of them were connected together, the third was quite separate.

*Ovarian Tumour.* Dr. GRIMSDALE showed a specimen, removed from a woman aged 28, who died on the sixth day from peritonitis. The tumour consisted of one large cyst, with one or two small ones near its base. The peduncle was very short, and there was a portion of bowel closely adherent to that part of it that was left within the abdomen. The patient went on well for the first forty-eight hours; then the pulse began to rise, and there seemed to be great tension about the peduncle. One of the pins transfixing this was removed; and on the third day, the other, giving vent to pus from the lower part of the wound, which gave great relief; but the patient gradually sank. At the *post mortem* examination, general peritonitis was found to have taken place, and there was great purulent effusion.

Dr. GRIMSDALE observed that to bring forward an unsuccessful case was an unpleasant duty; but one from which he believed no honourable man can desist, in spite of taunts made at other societies. He believed that the instances in which unsuccessful cases are held back from the knowledge of the profession are very rare. In this case, he attributed the fatal result to the tension on the peduncle. This had not been short enough to determine him to leave it in the abdomen, and not long enough to fasten in the wound without risk of tension.

The CHAIRMAN was also of opinion that cases that had a fatal result were not often held back.

Dr. NOTTINGHAM read a case in which he had performed ovariotomy with success at the Liverpool Southern Hospital.

Mr. FLETCHER said that the two cases just brought forward were very similar in many respects; and the question arose how it was that one should fail, and the other be successful. The state of the peduncle seemed to afford the only explanation. How far is it safe, and under what conditions, to leave the peduncle in the abdomen. A former case, which he himself had reported, of removal of an uterine tumour, showed that metallic ligatures may safely be left even in the substance of the uterus. In Dr. Grimsdale's case, the tension on the peduncle made it necessary to take out the pins; and perhaps some pus had then escaped into the peritoneum, and caused the fatal result.

Mr. STEELE said that in the present state of this question, any suggestion that could at all lessen the danger of the operation was worthy of great attention. He wished to draw the notice of this society to a modification of the operation that had been tried with success some years ago at the Southern Hospital in this town by Mr. Minshall. An incision of the usual kind was made, and the sac exposed; then nothing more was done for some days, during which time adhesions took place; the tumour was then tapped, and allowed to drain out slowly, and then, after an interval, extracted. The case did well. Perhaps the delay might allow the parts in the abdomen to accommodate themselves to the gradual shrinking of the cyst; perhaps the condition of the peduncle might become modified. He thought this was worth the attention of ovariotomists.

Mr. HIGGINSON thought it possible to relieve the tension on the peduncle by introducing an India-rubber distensible pessary, to raise the uterus towards the wound in the abdomen. With regard to Mr. Steele's case, much could not be built on one successful case involving such an operation.

Dr. NOTTINGHAM showed that the modification alluded to by Mr. Steele would add very much to the danger and the difficulties of the operation. Supposing for a moment that the tumour was partly fluid and partly solid, and that the first incision had been made, and the proper amount of peritonitis had taken place, then we are to tap the cyst, then to wait again, and then, through the

original opening, which is now girt round with adhesion, to remove the tumour. He could imagine nothing more dangerous or more difficult.

Dr. GEE thought that the mortality in operations of ovariectomy must depend more on the condition of the patient than on the skill of the operator. We often see serious consequences follow slight injuries, and *vice versa*.

The CHAIRMAN said the mode of procedure spoken of by Mr. Steele could not facilitate the operation. As to its safety, could we hope for another successful case?

Dr. GRIMSDALE thought the chief danger would be from pyæmia during the time when the cyst is left draining away. He thought the whole proceeding most objectionable. With regard to leaving the ligatured peduncle in the abdomen in Mr. Fletcher's case, he only tied the vessels; whereas we should have to tie a large portion of tissue which must either slough or suppurate. If we could tie the separate vessels, and then return the peduncle into the abdomen, it might be well; but he did not think it practicable.

Mr. STEELE read the case he had mentioned at length from the BRITISH MEDICAL JOURNAL.

Mr. HIGGINSON asked if we could always tell on which side the peduncle was to be found? He had met with a case where a pelvic tumour existed for some time, and always obstructed labour; it used to become flattened, and so let labour proceed. After death it was found to be a tumour of the right ovary that had lain on the left side of the uterus, and was full of hair and bones.

Mr. FLETCHER thought the small vessels of the peduncle might be tied separately, and the peritoneal edges of the divided peritoneal edges of the divided peduncle stitched together. Secondary hæmorrhage is a rare thing, and not much to be apprehended.

Dr. NOTTINGHAM suggested that if the peduncle be long enough, we might cut out a triangular portion of it, and bring the cut edges together and place them in the wound. This operation of Mr. Minshull's was said to have been performed in 1853, and was only recently published. Was it from notes taken at the time, or from memory? He thought there must be some mistake about the case.

Mr. STEELE had seen Mr. Minshull's notes of the case.

Dr. GRIMSDALE said, with regard to diagnosing which ovary is affected, that if the right ovary, for example, is involved, we can push the tumour to the right side much more easily than from it. Out of eight cases operated on since the revival of the operation in Liverpool, five patients have recovered and three have died.

GENERAL BUTLER AND DR. WARREN STONE. A "returned prisoner" is contributing sketches to the *Mississippi* of life in New Orleans under "Butler's rule." In his last he writes:—"All the world knows old Dr. Warren Stone. He is celebrated for his great surgical skill, as well as for his greatness of heart, independence of character, and devotion to the South. This truly great man was selected by Brute Butler as 'a shining mark' upon which to cast his venom. He was accordingly arrested and brought into the presence of the tyrant. The doctor walked up to Butler without waiting to be asked, and said in an abrupt curt manner, 'Here I am, General, and I want to know what I was arrested for.' Butler looked at the doctor from head to foot, and said contemptuously, 'I had you arrested because you are a great rebel, and the influence of such a man as you are is dangerous to the community. I shall send you to Fort Jackson to get you out of my way.' The old doctor looked steadily into the repulsive, crooked eyes of his wicked enemy as he indignantly replied, 'Great rebel, eh! You'll send me to Fort Jackson, eh! I glory in being a rebel. You can send me to Fort Jackson, and be damned.'

## Correspondence.

### DR. SEMPLE'S CASE.

Drs. J. and W. BULLAR present their compliments to the editor of the BRITISH MEDICAL JOURNAL; and, in the entire belief that Dr. Semple acted "purely from conscientious motives," and as an expression "of sympathy on the part of the profession towards a most upright and conscientious member of it," they beg to second the suggestion of an anonymous correspondent of last week, and to enclose a cheque for £5 to the subscription he has suggested and commenced.

Southampton, December 25, 1862.

[The cheque received from Drs. J. and W. Bullar has been passed into the hands of the gentlemen who are making a collection for the purposes indicated in the note. EDITOR.]

### ANÆSTHESIA IN LABOUR.

#### LETTER FROM F. T. PONCIA, ESQ.

SIR,—Allow me to acknowledge the courtesy with which "C. de Cinq Maisons" replied, in your JOURNAL of December 20th, to some remarks that I offered on the above subject.

He states that his own experience gives a result not in accordance with Dr. Simpson's statistics, which I quoted, since in his own obstetric practice more fatal results have followed "what might be fairly termed easy labours", than protracted, difficult, and instrumental labours. It would be futile to cite statistics showing that other practitioners have not obtained these same results, for that would not alter the facts deduced from his individual experience; but, seeing that protracted and instrumental labours are the exception, I submit that the only fair way of determining the question at issue is to take the same number of ordinary cases (say a hundred) and of protracted and instrumental labours, and so ascertain whether the number of deaths to mother and child preponderate in the former or in the latter class of cases. Then it would be seen which of the two doctrines be the true one; viz., "the easier the labour, the greater the danger;" or, "the longer and more difficult the labour, the greater the danger." For my part, I conceive that the statistics of Dr. Simpson, collected from various sources, prove the latter proposition; and to these I would refer, in order to save space. I am aware that high obstetric authority of the past and present generation has sanctioned a different sentiment; that it has been asserted that "neither the violence nor the continuance of parturient pains is productive of injury to the constitution;" and again by another, that "labour pains are endured without any detriment;" but statistics yield a different result; and on these, rather than on mere dicta, I would fain base a conclusion—especially, too, when I find that writers, whose works are text-books, speak complacently of the harmlessness of labour pains in one place, and in another demonstrate that exhaustion will result from their long continuance; and that the uterus, like any other muscular structure, cannot sustain an unlimited amount of exertion. I am of opinion, therefore, that my idea of the pain and process of labour is neither exaggerated nor erroneous; that the "pangs" and "agony" of parturition have as legitimate a right to be annulled as the pain arising from a surgical operation; and, since the exhibition of chloroform does not impede the parturient process, nor prove fatal to mother or child, when judiciously administered, I esteem it as a boon, and its originator—Dr. Simpson—as a benefactor to humanity. The objections at present urged against its employment

are the same in substance as have ever been directed against great and important discoveries, not only in medicine, but in science generally. Prejudice, however, is doomed to die; and *mere objections* cannot withstand the evidence of facts, the test of experiment, and the force of truth.

Hoping that your correspondent will view all that I have said in a friendly spirit, and with all deference to his superior experience,

I am, etc., F. T. PONCIA.

Hockley, Birmingham, December 1862.

### COTTAGE HOSPITALS.

LETTER FROM ALBERT NAPPER, ESQ.

SIR,—Pray accept our acknowledgments and thanks for the favourable notice of our village hospital in the JOURNAL of the 3rd inst. Your concluding remark, however, demands for me a reply, for the insertion of which I shall feel obliged.

As may be well supposed, in soliciting funds for the establishment of a normal institution, many little difficulties have to be encountered; and in carrying the project into execution, it is most essential to avoid the risk of failure through undue expenditure. It was with this view that I followed in the wake of the rector, to whose liberality and active assistance the hospital is mainly due for its existence, as well as to deprive it of the least pretence of having been started for my own private gain.

I have pleasure in stating that the trustees, both this and the preceding year, liberally offered to reimburse my expenses for drugs, etc. I fully appreciate the justice of your remarks; and recommend those establishing similar institutions to follow your advice, so far as regards the cost of medicines, etc.; but I more than doubt the propriety of medical officers to public charities receiving salaries for their services; which would not only endanger their tenure of office by making it one of competition, but would destroy the independence and freedom of action so essential to a due performance of their duties.

There is, however, a class of men, for the most part retired practitioners, who, in the prostituted name of charity, give advice gratis to the families of substantial tradesmen, farmers, &c., and even gentlemen, who are well able to pay the usual compensation to the practitioner of the neighbourhood. To these your strictures cannot be too strongly applied; and I am sure I may venture, in the name of the general practitioners, to thank you for your endeavour to mitigate the evil.

I am, etc., ALBERT NAPPER.

Cranley, near Guildford, January 6, 1863.

A TEETOTAL CONFEDERATE, GENERAL STUART. There have been many English officers, particularly in the East Indian service, whose endurance in the saddle has been regarded as unequalled, but I doubt whether any Englishman ever exhibited such superiority to bodily fatigue as is almost nightly evinced by the gay cavalier who knows every hospitable roof within a dozen miles of his headquarters (and what roof is not hospitable?), and, accompanied by his banjoplayer, visits them by turns night after night, returning usually to his hard-earned rest long after the midnight hour has flown. With the earliest dawn of morning, the first voice, calling gaily for breakfast, is that of the midnight merry-maker, who rises the picture of health, good-humour, and strength. It may be noticed *en passant* that to the circumstance that he has never touched tobacco in any form, or any wine or other liquor, General Stuart attributes much of his health and vigour.

## Medical News.

APOTHECARIES' HALL. On January 1st, the following Licentiates were admitted:—

Churton, Thomas, Poole, near Odley  
Hope, Edmund, Eastern Dispensary, Leman St., Whitechapel  
Sargent, George Pearce, Albauy Road, Walworth

At the same Court, the following passed the first examination:—

Stubbs, Henry, General Hospital, Birmingham

### APPOINTMENTS.

BORTHWICK, Alexander, M.D., appointed Consulting Physician to the Crichton Institution, Dumfries, in the room of the late James Grieve, M.D.

CLARKE, Alfred, Esq., appointed Medical Attendant to the Gloucester Municipal Charities, in the room of the late W. M. Meyler, Esq.  
DICKSON, John, M.D., appointed Physician to the Dumfries and Galloway Royal Infirmary, in the room of the late J. Grieve, M.D.

### POOR-LAW MEDICAL SERVICE.

BOTHWELL, George G., Esq., Medical Officer for the Rathmellen District of the Milford Union, county Donegal.

HUNTER, Charles, Esq., Medical Officer to the Aberlemne District and Forfar Workhouse.

JEYNES, William, Esq., Medical Officer to the East Croydon District of the Croydon Union.

LANDDOWN, Joseph R., L.R.C.P.Ed., Medical Officer to Workhouse and District No. 1 of the Newcastle-under-Lyne Union.

### ROYAL NAVY.

BOLSTER, George, Esq., Assistant-Surgeon, to the *Egmont*.

BORROWS, Robert, M.D., Surgeon, to the *Ariel*.

ROLSTON, George, Esq., Assistant-Surgeon, to the *Egmont*.

WILLES, George J., Esq., Surgeon, to the *Egmont*.

WILSON, Daniel, Esq., Surgeon, to the *Osprey*.

VOLUNTEERS. (A.V.—Artillery Volunteers; R.V.—Rifle Volunteers):—

STEPHENSON, J., M.D., to be Surgeon 1st Norfolk A.V.

To be Honorary Assistant-Surgeon:—

WALKER, H., Esq., 15th Staffordshire R.V.

### MARRIAGE.

BARBER, Henry, M.D., of Ulverstone, Lancashire, to Frances, daughter of George STUNT, Esq., of Tottenham, London, on January 5th, at Holy Trinity Church, Tottenham.

### DEATHS.

BRAUN, Carl, M.D., at Wiesbaden, on December 9, 1862.

CADENHEAD, John, M.D., at Aberdeen, aged 64, on Dec. 31st, 1862.

CHASE, On December 29th, 1862, at Tottenham, Sarah, widow of Edward Chase, Esq., Surgeon, of Luton.

COOPER, James, Esq., Surgeon, at Liverpool, aged 60, on Jan. 6.

HARRIS, On December 20th, 1862, at Wandsworth, aged 2 years and 10 months, Ida F. E., daughter of William Harris, Esq., Surgeon.

RYMER, On December 30th, 1862, at Ramsgate, aged 68, Elizabeth, wife of James Rymer, Esq., Surgeon.

ANOTHER 'MEDICAL CORONER. Mr. J. S. Davies has been elected by the Town Council of Shrewsbury, coroner for the borough.

WESTMINSTER HOSPITAL. Mrs. Chadwick (whose late husband made a munificent donation to the Westminster Hospital), has invested £700 in consols, to produce an annual sum of £21, which is to be given in prizes to students. The following resolution has been passed by the lecturers, in whose names the sum is vested:—"The lecturers of the Westminster Hospital School of Medicine, desire to convey to Mrs. Chadwick the expression of their deep obligation to her for the munificent endowment she has made for the purpose of promoting the education of the students of the medical school. They entertain a firm belief that the rewards offered by this endowment to industry and intelligence, will afford the most efficient means for stimulating the best energies of those who are being educated at the hospital for the medical profession."

**WOUNDS IN BATTLE.** The medical report of the wounded in Reynold's corps, Gibbons's division, at Frederickburg, gives an account of 859 cases. No less than 498 were hit in the leg or foot, 45 in the hips, 10 in the abdomen, 42 in the chest, 48 in the head and neck, 145 in the arm or shoulder, 61 in the hand and forearm, and 10 contrived somehow to get shot in the back. Chloroform was administered to 186 with complete success.

**STRYCHNINE POISONING.** A man named Heimsath, in the employment of Messrs. Hopkins and Williams, wholesale druggists, of New Cavendish Street, has died from poisoning by strychnine. On Christmas-eve he and three of his fellow-servants had some beer at their place of employment, and a quantity of it being left, it was put by one of the men into a glass bottle. On the Friday following Heimsath drank some of the beer, immediately fell on the floor in convulsions, and shortly afterwards died. A *post mortem* examination showed that death had been caused by strychnine; and on the beer in the bottle being analysed, it was found to contain a large quantity of that poison. There was some suspicion of foul treatment. The jury at the inquest on the body returned an open verdict.

**PATHOLOGICAL SOCIETY OF LONDON.** The seventeenth annual meeting of this society was held on January 6th. The Council reported that the career of the society continued to be marked by unabated prosperity. Notwithstanding circumstances, the influence of which had tended in some degree to limit the rapid rate of progress which the Society had maintained since its origin in 1846, its numerical strength had never been greater than at the present time. The interest of the meetings had rather increased than otherwise; and the supply of valuable preparations, not only from our own country, but from abroad, had never been at any previous period surpassed. The financial statement exhibited a balance in the hands of the treasurer of £187:18:5½. A portion of this will be added, according to the usual custom, to the Society's funded property, which now amounts to £129:6:7. The following officers and council were elected for the ensuing year:—*President*, Prescott G. Hewett, Esq.; *Vice-Presidents*—W. Jenner, M.D.; Sir John Liddlel, M.D., C.B., F.R.S.; A. B. Garrod, M.D., F.R.S.; G. Johnson, M.D.; Wm. Coulson, Esq.; J. E. Erichsen, Esq.; John Hilton, Esq.; G. D. Pollock, Esq. *Treasurer*—R. Quain, M.D. *Council*—T. A. Barker, M.D.; G. Budd, M.D., F.R.S.; A. Clark, M.D.; W. D. Chowne, M.D.; G. Harley, M.D.; S. J. Goodfellow, M.D.; J. W. Ogle, M.D.; J. E. Pollock, M.D.; G. D. Gibb, M.D.; R. Barwell, Esq.; B. E. Brodhurst, Esq.; W. White Cooper, Esq.; W. H. Flower, Esq.; J. G. Forbes, Esq.; T. Holmes, Esq.; J. Pyle, Esq.; S. J. A. Salter, Esq.; T. Bryant, Esq.; J. W. Hulke, Esq.; E. Ray, Esq. *Honorary Secretaries*, J. S. Bristowe, M.D.; Henry Thompson, Esq.

**IRISH MEDICAL ASSOCIATION.** The Irish Medical Association held a meeting last week, at the Limerick Junction Hotel, to consider matters which Dr. Jacob, of Maryborough, their chairman, said, "were of vast importance to the public generally, as well as to their own profession in particular." The subject which he wished to bring under their notice was the registration of births and deaths in Ireland. At present no legal provision was made for such registration, and consequently the vital statistics of the country are very imperfect. Besides the chairman, the president of the College of Surgeons, Dr. Mackesy, Dr. Harvey, Dr. Ryan, Dr. Elliott, and many others addressed the meeting, in order to prove that only highly qualified medical practitioners were fit to preside over the collection and arrangement of those vital statistics, and that only in such hands could there be a safe and trustworthy registration. The meeting was quite

unanimous on these matters. They also complained of the paltry remuneration granted to medical officers for their important and laborious services, and resolved to get a more suitable recognition of the value of their services. They agreed that the *minimum* salary of a dispensary medical officer should be £100 a year.

**A MILD DECEMBER.** Mr. T. L. Plant of Birmingham writes to the *Times*: "The month just closing has been so remarkably mild that a few particulars, compared with former seasons, may be interesting to some of your readers. On the morning of the 22nd the *minimum* register stood at 29°, which was the only occasion when the temperature declined below freezing point. This is extraordinary for December. The following are the mean values of temperature for this month for the last four years, compared with the average for ten years:—December mean temperature.—1859, 34°; 1860, 34°; 1861, 38°; 1862, 43°; average of ten years, 36°. It will thus be seen that the present month commanded a mean of seven degrees over the average for December from ten years observations. December 1837, was mild. Frost set in on the 1st of January following, and lasted eight weeks. The Thames was partially frozen over. December 1854, was also mild, and frost commenced on the 16th of January and continued five weeks. The Severn was frozen over at Worcester, and the Thames was again partially frozen over. Both the above seasons were remarkable for weather of a similar character to the present month before the frost commenced—namely, open, mild, and with frequent high winds."

**POLLUTION OF THE THAMES.** The medical officers of health of the metropolis met lately to consider a proposal of the engineer of the Metropolitan Board of Works to discharge the sewage of the western district of the metropolis into the Thames near Cremorne Gardens; Dr. Thompson of Marylebone in the chair. Dr. Burge of Fulham read an elaborate report on the subject, whereby it appeared that the Metropolitan Board intends to deodorise the sewage of the metropolis west of the Ranelagh sewer, and afterwards to discharge the same into the river near Cremorne. The area extends seven miles west of Chelsea Hospital, as far as Brentford, embracing one-third of the metropolitan area, and one of the most increasing in population. In the opinion of Dr. Burge and various eminent scientific men, quoted by him, the discharge of such a large amount of poisonous matter into the river would have a most deleterious effect upon the metropolitan population. Dr. Thomson read a report of a preparatory committee convened to consider the question, showing that the area included twenty-one square miles and a half, or one-eleventh part of the metropolitan sewage, amounting to about 10,000,000 gallons daily, which would be collected into a reservoir two acres in extent, near Cremorne, for deodorisation, previous to discharge into the river, by perchloride of iron. The committee considered the perchloride of iron was useful only in the reservoir itself, and not as tending in any way to disinfect the river. The meeting, on the motion of Dr. Liddle and Dr. Aldis, adopted the report, which was entered on the minutes. Dr. Burge moved, "That, in the opinion of the Association of Medical Officers, the proposed deodorisation of the sewage of the western district of the metropolis, and its subsequent discharge into the River Thames, will be ineffectual in its operation, pernicious in its effect upon the river, and subversive of the principle upon which the interceptive scheme was originally based." The motion was carried, and a copy directed to be forwarded to all the vestries and local boards. It was also agreed that a deputation of the Association wait upon the Metropolitan Board to oppose the proposed scheme.

## OPERATION DAYS AT THE HOSPITALS.

MONDAY.....Royal Free, 2 P.M.—Metropolitan Free, 2 P.M.—St. Mark's for Fistula and other Diseases of the Rectum, 1.15 P.M.—Samaritan, 2.30 P.M.—Lock, Clinical Demonstration and Operations, 1 P.M.

TUESDAY....Guy's, 1½ P.M.—Westminster, 2 P.M.

WEDNESDAY...St. Mary's, 1 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.

THURSDAY....St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—London, 1.30 P.M.—Great Northern, 2 P.M.—London Surgical Home, 2 P.M.—Royal Orthopaedic, 2 P.M.

FRIDAY.....Westminster Ophthalmic, 1.30 P.M.

SATURDAY....St. Thomas's, 1 P.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY. Medical Society of London, 8.30 P.M. Clinical Discussion. Mr. Bishop, "On the Artificial Hand of Selgr. Gallegos"; and other Cases.—Royal Geographical.

TUESDAY. Royal Medical and Chirurgical Society, 8.30 P.M. Mr. John Dix (of Hull), "On the Wire Compress, a substitute for the Ligature"; Dr. A. B. Buchanan (of Glasgow), "Case of White Fibro-Serous Discharge from the Thigh."—Zoological.

WEDNESDAY. Microscopical.—Society of Arts.—North London Medical.

THURSDAY. Royal.—Antiquarian.—Linnæan.—Chemical.—Harveian.

FRIDAY. Western Medical and Surgical Society of London, 8 P.M. Mr. Jones, "Some Points in connection with Cerebral Hæmorrhage."

SATURDAY. Medical Officers of Health.

## POPULATION STATISTICS AND METEOROLOGY OF LONDON—JANUARY 3, 1863.

[From the Registrar-General's Report.]

## TO CORRESPONDENTS.

\* \* All letters and communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen St., Lincoln's Inn Fields, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

DR. MAYNE AND DR. FOWLER.—SIR: On a suggestion, that notification should have been made in the journals of the reference, to professional gentlemen, of the dispute between Dr. Robert Fowler and me having been entered into, I beg leave to state that Dr. T. B. Peacock, 20, Finsbury Circus, has been named by Dr. Fowler as his referee; and Dr. A. Meadows, 9, Cavendish Place, Cavendish Square, has kindly consented to act as such for

Leeds, Jan. 6th, 1863. Yours, etc., R. G. MAYNE.

MR. LOCKE.—The late celebrated engineer was a strong opponent of the Netley Hospital. In a review of his life, we read as follows:—"His opposition to the Netley Hospital job was tenacious, though not very effectual."

AN APPEAL.—SIR: I would venture through your columns to make an appeal to the medical profession on behalf of the widow of the late Mr. Henry Baker Armstrong, of Pembridge, Herefordshire, and Fryers Town, Australia. Mrs. Armstrong has just returned from Australia, where her husband died, leaving her destitute, with three small children. Her passage home was paid by several of the residents and medical men on the Bendigo district. She is anxious to obtain a situation as mistress of a school, or to engage in some way of business. Having known her late husband and Mrs. Armstrong, both in Australia and in England, I can recommend the case to the profession and to the public. There may be some of Mr. Armstrong's friends who knew him at Bartholomew's Hospital. May I ask them to send some donations for the benefit of his widow and children? J. Paget, Esq., of Bartholomew's, and Joseph Toynbee, Esq., both knew the case, and will, I am sure, recommend it. I shall be very happy to give further, and, if necessary, more minute and painful particulars, by letter, to any inquirer; and will also gladly receive and acknowledge subscriptions, large or small, for Mrs. Armstrong.

I am, etc., J. C. DENNY,

Dec. 31st, 1862. Senior Curate of Wellington, Salop.

ANÆSTHESIA IN FEMALE DISEASES.—SIR: Several correspondents of late have addressed the JOURNAL as to the necessity of an inquiry into the usefulness of chloroform in female diseases and midwifery; but there is scarcely one department of practice in which the report of the use of anæsthetics is so favourable, or the advantage so generally acknowledged. The late outburst of cases of ovariectomy has been indirectly due to the soothing and beneficial assistance of anæsthetic agents; for we cannot believe that, if we had no chloroform, poor women would submit to this truly terrible cutting and mutilating operation. I am anxious at present to say that, having administered chloroform or ether in something like thirty of these cases, and having studied its action in another large number, I have been remarkably struck with the "law of tolerance" of chloroform in ovariectomy. One is sometimes asked if in such cases chloroform is to be recommended. I believe this very remarkable tolerance is partly due to the fact that there is very little hæmorrhage in ovariectomy; and, I know now from experience, that there is not much, if any, tendency to syncope in the tapping the ovarian cyst (the early part of the operation), as was at one time so strongly laid down in books, and still believed to follow the tapping of ascites. I find that some persons shake their heads at chloroform, from fear of this tapping or syncope of books; but the dread is purely ideal; and if asked if I recommend chloroform in ovariectomy, I usually say, I do so with more probability of safety than in a minor or trivial operation, such as tooth-drawing. At any rate, one can seldom go wrong as to syncope, if he has some ether also near him when using the chloroform, and administers them alternately. The ether, I find, acts very well in preventing faintness or syncope. With regard to the formula of tartarised antimony of Mr. de Cinq Maisons, as he admits his experience is limited as to chloroform, I would offer him a hint; viz., never to go from tartarised antimony to chloroform too quickly, or he may have syncope—in midwifery, a rather alarming thing, if one is administering chloroform with one hand to a poor woman, usually the left, and supporting the perineum, as the child is entering the world, with the right. I would only say further, that there is probably not a single well attested fatal accident from chloroform in midwifery.

I am, etc., CHARLES KIDD, M.D.

25, Sackville Street, December 23rd, 1862.

P.S.—The cost of the last volume of the Pathological Society's *Transactions* was increased in consequence of the American war! The binding of each volume was this year dearer in consequence of the rise in the price of cotton.

COMMUNICATIONS have been received from:—MR. ERASMUS WILSON; DR. P. M. LATHAM; MR. A. B. STEELE; THE HONORARY SECRETARY OF THE WESTERN MEDICAL AND SURGICAL SOCIETY OF LONDON; MR. A. NAPPER; DR. TOOGOOD; MR. W. WEBER; DR. T. K. CHAMBERS; DR. LIONEL BEALE; MR. F. T. PONCIA; THE HON. SEC. OF THE ROYAL MED. AND CHIR. SOCIETY; MR. J. VOSSE SOLOMON; MR. W. M. BAKER; MR. PAGET; MR. E. # General Remarks

ON THE

## PRACTICE OF MEDICINE.

BY

P. M. LATHAM, M.D.

### THE HEART AND ITS AFFECTIONS, NOT ORGANIC. (*Continued.*)

#### III.—*The Frequent Pulse at its Highest Degree of Significance. Cases.*

THERE are things which, as they ordinarily present themselves in nature, are so beset with collaterals that, but for their sometimes appearing in simple forms, they could never be fairly understood. Such, among the symptoms of disease, is often the frequent pulse. It is one of a crowd, and is lost in a crowd. It is not duly attended to among many as urgent and as pressing for notice as itself. But then it sometimes stands almost or altogether alone. There is the disease; and all that can be reckoned as belonging to it in the nature of a symptom, all that can serve to direct its treatment and prognosticate its event, is a very rapid pulse.

Such cases are rare; but still they occur often enough to afford us opportunities of seeing and noting this symptom of the frequent pulse in its simplest, its most elementary, and yet most prominent form, and the fittest and best to develop its true pathological meaning.

I was called one Friday, at midnight, to visit a young married lady, aged 21, whose state had given just alarm to her medical attendants. Her pulse was too rapid to be counted, and so feeble that it could only just be felt. She made no complaint of pain; and no questioning, no examination by pressure of the abdomen especially, could elicit the least expression of it. The abdomen was soft, and very slightly distended. The tongue was quite clear and moist; the extremities quite warm. Moreover, there was perfect consciousness; and she expressed surprise at the apparent anxiety of those around her.

Here the only present symptom was the pulse countless from rapidity, and scarcely perceptible from feebleness. But there had been another symptom. On the previous Wednesday, at 3 P.M., suddenly and without warning, there had been a long and severe rigor. No reaction followed, when it passed away; the pulse became extraordinarily rapid and feeble, and it had so continued ever since.

At 10 A.M. the next day (Saturday), the state of things was still the same, except that the abdomen had become flattened in consequence of evacuations which had taken place in the course of the night. There was still no positive symptom, but the pulse most rapid and feeble. At 10 P.M. this symptom no longer remained. The pulse was imperceptible at the wrist. The hands were cold. Consciousness remained, and even intelligence; and there was evidently no feeling on the part of the patient that she

was going to die. She died in the night; I did not learn at what time.

Observe: of this rapidly fatal disease (if disease it was) there were only two symptoms—the long and severe rigor, and the rapid, feeble pulse. But they were not, either one or the other, symptoms in the strict pathognomonic sense, being common to twenty diseases different in kind, and diagnostic of none. But symptoms they were, and both alike, of things incident to all diseases, and terrible when they occur. The inceptive rigor denoted the shock suddenly given to the powers of life; and the countless feeble flutterings of the heart, which followed it, denoted their surrender.

Now, as to the nature of the disease in this case, we must seek it in things prior to the inceptive rigor, since it certainly did not appear in what occurred afterwards. This lady had been confined eight days. The labour was favourable. But the placenta was retained, and had to be torn away. Still she had gone on favourably in every respect until the rigor. There was nothing more to be told of previous history; and this, and experience of the like, were enough to show the nature of the disease, and that it was puerperal fever. But shall I say “that it was”, or rather “that it would have been?” The morbid element was taken up, and became a quick-working poison to the powers of life. The disease had either only just emerged and was cut short, or it never emerged at all. The disease, so to speak, killed itself; it killed itself in the birth. Its first impression was a fatal shock; and there followed, not the symptoms proper to its own nature, but the one symptom of coming death—this countless fluttering of the heart.

I was suddenly summoned to a lady, about 40 years of age, who was to all appearance brought at once within the grasp of death. She was pale and cold, and her lips were livid; and her pulse was of a countless frequency, and just perceptible, and no more. Her mind was clear; and she could just be heard to whisper a few articulate words, telling me that she saw all things in a mist, and did not well distinguish one object from another; and that she seemed as if she were going to be suffocated. This looked awfully like dying. And into this condition she had passed in the course of two hours.

I had no other expectation than that she would die immediately. But hour after hour passed away, and she still lived. Days and nights, even five days and five nights, between Tuesday and Sunday, passed away, and she still lived. She lived, but without the slightest appearance of rallying, and without the least token of any positive disease. The countless, scarcely perceptible pulse, comprised all the symptoms. Brandy, ammonia, ether, anything and all things that could stimulate, were given (for the power of swallowing remained), every ten, or every five, or every three or two minutes, night and day. But they produced no reaction. They kept the heart just moving, and that was all. The pulse was sometimes perceptible, and sometimes not; and several times, when it was actually gone, and all was over, as it seemed, life and a pulse were brought back again by a larger supply of brandy.

After five days and five nights thus spent, a change took place; and it was all at once. It was within a certain half-hour. As I sat by her bedside, I found her pulse had for the first time become dis-

tinct enough to allow me to count it. Instead of a confused flutter, it gave 120 distinguishable beats in a minute. It continued perceptibly constant to this number for one half-hour, without the help of brandy. Presently what was dusky became red, what was cold became warm; and so much of reaction brought so much of hope.

But how did this frightful mystery end? How did it clear itself up? The tongue became red, then intensely red, then papillated; and then a rash diffused itself over the neck and chest, then over the whole body. And all was consummated in a regular attack of scarlatina, which went through its course without any unusual or unfavourable incident, and the patient got well.

In the first of these two cases, there was the highest presumption *à priori* (perhaps the proof), that the puerperal poison had gained access to the blood, and had entered into deadly conflict with the powers of life. Had the conflict been less than deadly, it would have had its natural issue in some authentic form of puerperal fever, which would have had its own perils. In the second case, there was the positive proof, *à posteriori*, that the scarlatina poison, gaining access to the blood, did for five days and five nights keep up an all but deadly conflict with the powers of life. But life holding out, the disease appeared as the natural consummation at last.

Now these two cases have the force of crucial instances. They are experiments of Nature's own contriving, and exclude all fallacy in the result. They prove the true significance of the frequent pulse; viz., that it is not a thing of disease as belonging to its essence, but a thing of disease and of all that concerns disease only as being a sign and a measure of the degree in which life and the powers of life are then brought to feel and to suffer, and to languish and fail. And this is the interpretation which the frequent pulse will be found to bear in the whole range of diseases in which it occurs, and in all the conditions, few or many, simple or complex, with which it is combined.

#### *Further Commentary on the Foregoing Cases.*

But, in these two remarkable cases, everything was uncommon and extreme. They furnished full-drawn representations of the rapid pulse, and, as such, well suited for studying its meaning; not, however, *exaggerated* representations, but strictly those which Nature offered. Yet it is startling to be told that the meaning found to belong to the rapid pulse in these two cases is the same *in kind* which it has in all diseases whatever. The difference between great and small, or of mere magnitude, in things of the same kind, is often so considerable, that practically it is difficult to look upon them and believe them to be of the same kind in fact. But, in the things pertaining to diseases, identity of kind, when it is real, ought to be carefully preserved, for the sake of doctrine and of truth. Mere magnitude, however, forces itself into notice. And so it ought; for life and death continually depend upon it, and it cannot be ignored with safety to practice.

In the two cases which have been cited, we have spoken of *life* and the *powers* of life, and of the rapid fluttering pulse bearing sole and infallible witness to their utter prostration and failure. But these expressions denote the truth popularly, rather than

pathologically. Nevertheless, they *do* denote it. Still they are expressions which, being employed about diseases, are suited only to things of the greatest magnitude in their kind. Accordingly, it would be too much to speak of *life* and the *powers* of *life* being reached and implicated in every case of disease wherein the pulse was frequent beyond the standard of health. But it would be neither too much nor beyond the truth to speak of something being reached and implicated which holds peculiar relations with life—something, belonging to our organisation, which communes with life more nearly and at once than through the circle of our grosser and more intelligible functions. And this is the nervous system.

Now the nervous system has the heart for its gnomon or finger of the clock. This notes, by the rate of its movement, the various degrees in which the nervous system is affected, from the least to the greatest. It is the greatest which must still engage our attention, and the rapid pulse the index of them. And the cases which have been just cited will help to explain them. To press the language of our analogy a little further, for the sake of illustration, we have already seen in these two cases the index hurrying rapidly round the dial-plate, and telling that, from some cause or other, the mechanism within was running down, and, if it were not arrested, that it would quickly stop. Even prior to any outward presentments to give assurance of disease, even earlier than its known beginning, we have seen the countless fluttering of the heart and arteries give token of the nervous system already under trial of mortal suffering, and ready to let life go for ever. But there is no reason in the nature of things (as far as I know) why a morbid poison, or any other element of disease, should not affect the nervous system soonest of all, and sooner than the blood and blood-vessels, to which it properly belongs to work out disease into its cognisable products and realities. Only experience says that it is rare, very rare.

#### *Frequent Pulse still at a very high Degree of Significance. To what Conditions of Disease it belongs.*

Not until disease is shaped and realised into something which can be seen or heard or touched, and can be called by a name, is it wont to engage the nervous system perilously; and should the particular disease, according to its nature, have to go through a stated course to a certain end, and so admit a probable measure of its duration, it will not commonly be until towards its decline that extreme peril to life is indexed by extreme frequency of the pulse. But the time is often anticipated. This sign of fearful significance—this countless fluttering of the pulse—may break in upon the disease at any stage of its progress, either early, even very early, or in its midcourse. And when it does, some notable thing has often preceded it, well capable of giving a shock to the nervous system. Sometimes a sudden profuse diarrhœa has been enough to account for it; sometimes a hæmorrhage; sometimes an unhappy error of treatment by larger depletion than the patient could bear; sometimes pain—severe, long, uninterrupted pain; sometimes loss of sleep; sometimes the solution of some organic texture within, as the rupture and perforation of a bowel. Sometimes, however, and oftenest, nothing incidental or casual

can be found to bear the blame, but only the malignant nature of the disease itself.

Still there is a hope for these cases ; but it is small. Yet small hope is made much of by the hopeful, and often serves them for a great encouragement. And so it must and had need do now, or there will be no saving of life.

And there is a treatment of these cases. Death is inevitable, if they are left to themselves. None ever recovered but by known, palpable, and adequate means. The treatment is simple enough. A single symptom has absorbed all other indications of treatment into itself, and remains our sole infallible guide what to do. The countless fluttering pulse now stands for everything. Watch must be kept upon it and its meaning. And its meaning is, that the nervous system is ready to sink into death. Accordingly, stimulus is to be given so *often* and so *much* as will keep it going and prevent it from coming to a stop. All this is simple enough in the telling. I wish it were so in the doing. As much, perhaps, has been told as can be told. But the "how often" and the "how much" are the things upon which life now hangs, and a judgment has to be exercised upon them every hour or many times every hour. Therefore the sick man has a poor chance, unless he can now have the services of one intelligent nurse at least entirely to himself. To have also one intelligent physician constantly within reach would not be at all beyond his needs. But it is useless to insist upon what is generally impracticable. Nevertheless, many cases within my experience, in which life has been rescued contrary to all probable calculation, have had this unspeakable advantage ; and some of them have occurred in the family of physicians.

But be it borne in mind that we have now to do with a part only of a very great subject. The nervous system, and its actings and sufferings under disease, this is the great subject ; and our small part of it is the frequent pulse. Nevertheless, small though it be, it is the part which especially offers itself as a handle to the whole. The part, by which we can best lay hold of it, and apprehend it, and study it, and turn our little knowledge of it to practical uses and benefit.

I wish still to keep hold of this handle that I may show the share the nervous system has in the graver diseases, and how it often determines their form, their course, and their event.

It is only in the most chronic diseases that the nervous system does not sensibly participate. All which show an appreciable progress from day to day ; all to which fever in any measure belongs, either essentially or as an accident ; these cannot exist without the nervous system feeling them and showing that it feels them. Now, almost all such diseases have, in respect of their essence, a due course to run and an end to reach. Phlebitis has its mixture of pus with the blood, and its deposit in abscesses within and without ; erysipelas has its diffused redness and swelling ; scarlatina one form of rash, and measles another ; small-pox has its pustules ; typhus has its petechial maculæ of the skin, and the typhoid malady has its tumescence and ulcers and sloughs of the intestinal glands. And these several conditions represent the essence of the several diseases, and show it to be different in each. But there are other things belonging to them all in common, which have great force in guiding their treatment and

ruling all concerning them. It is, indeed, by the essential element of these diseases, and by its mode of working, whether diffused through the veins, or collected in abscesses, or sprinkled over the skin, or scattered through the bowels, that each fulfils its course and accomplishes its end. But it is the great vascular system and the great nervous system that are most conspicuously engaged, and acting, and suffering all the time and in all of them, and the sum of their acting and suffering is called fever. The number of the pulse is our chief handle for apprehending the part specially borne by the nervous system.

If the fever be small, with moderate sympathy of the nervous system, there will be moderate frequency of the pulse, with moderate increase of its power, and thus much is natural and perhaps needful. If the fever be greater, with more sympathy of the nervous system, the pulse will rise both in frequency and force. And still all is natural and all is in harmony.

But, as the sympathy of the nervous system continues to increase, and the frequency of the pulse to increase along with it, anxiety begins to arise ; yet the strength of the pulse will still be the vital safeguard. Let, however, the sympathy of the nervous system increase more and more, and the number of the pulse run on to greater and greater frequency, then assuredly its strength will languish ; and if the balance be not soon redressed, it will become a countless fluttering. And to such extremity is the man now reduced, that this countless fluttering of the pulse will represent all that is vital in him, and all that can be treated in the disease. Gradually or abruptly, in any of the diseases mentioned, this may become the condition of the patient. It is often witnessed in the typhus and typhoid fevers of late years.

This deadly sinking of the nervous system, represented by the countless fluttering of the pulse, this most terrible incident of febrile diseases ; coming on at their beginning, or middle, or end, sometimes abruptly, sometimes gradually, not absolutely hopeless, and not absolutely beyond reach of a remedy, deserves to have all told of it that observation has learnt. Well, then, having once begun, it may continue many days or nights (three or four) uninterruptedly. And during all that time, the pulse will continue countless and almost imperceptible ; abating nothing of its frequency and gaining nothing of power for all the wine and spirits administered, but only just kept going and prevented from coming to a standstill. And thus the quantity even of spirits given in twenty-four hours has amounted to pints. And after these three or four fearful days and nights, the pulse may become of a calculable number again and of an appreciable power, and maintain itself at the less number and the greater power with a less amount of stimulus, and henceforth the disease will pursue its course exempt from the alarm of this particular symptom, which is the sure expression of the nervous system collapsing into death. But that the pulse should go on fluttering, and the nervous system go on collapsing into actual death, is the more common event.

Or this terrible incident of febrile diseases may occur after a different manner. The pulse will be countless and fluttering for a few hours, and then, under the use of stimulus, it will recover power and a

calculable number for a few hours; and then become countless and fluttering again. And after the nervous system has thus gone on to sink and to rally alternately for a few days, it will rally permanently, and the pulse become slower and steadier, and the disease will proceed free from this peculiar peril. But more often the nervous system will sink irrecoverably, and the pulse flutter and flutter on, and the patient die.

There is a very curious and interesting circumstance well worth our notice, to which my observation, if it do not deceive me, has often borne witness as a matter of fact. It is that the nervous system having reached the degree of collapse, indexed by the countless fluttering pulse, carries with it the pathological consequence of suspending for the time the course of the disease. Whatever be the disease which it attends, whether scarlatina, or measles, or erysipelas, or small-pox, and whatever be the stage it has reached, at that stage it will stop, and all specific morbid actions come to a suspense and standstill; perhaps to be resumed, perhaps not. To be resumed, when (if ever) the pulse comes within some clearly calculable number, and remains steadily within it, notifying the steady recovery of the nervous system. Not to be resumed, if the pulse goes on fluttering, although many days have yet to pass before the nervous system has collapsed into death. It is curious how disease thus under the all-subduing constraint of the nervous system, and halting for one, two, three, or four days, will, when that constraint is taken off, take up its course again from the stage at which it was arrested, and duly proceed to its end.

What took place in the remarkable case before cited is a specimen of the same thing in kind as that which now engages our attention; only there the disease was latent in its state of incubation; here the disease is manifest and already formed. There the disease had not yet begun, and the failing nervous system still withheld it from beginning during several days; here the disease being already formed, the failing nervous system withholds it from proceeding during several days.

**MILK.** Milk has been so often analysed, that it would seem no further facts could be elicited regarding this important liquid. Professor Boedecker, however, has just completed a series of experiments conducted on quite a new principle. The question he proposed to himself was whether milk obtained at any hour of the day always presented the same chemical composition or not; and he has arrived at the result that the milk of the evening is richer by 3 per cent. than that of the morning, the latter containing only 10 per cent. of solid matter, and the former 13 per cent. On the other hand, the water contained in milk diminishes by 3 per cent. in the course of the day; in the morning it contains 89 per cent. of water, and only 86 per cent. in the evening. The fatty particles increase gradually as the day wears on. In the morning they amount to 2.17 per cent.; at noon, to 2.63, and in the evening to 3.42 per cent. This circumstance, if true, would be very important in a practical point of view. Let us suppose a kilogramme of milk to yield only the sixth part of its weight of butter; then the milk of the evening may yield double that quantity. The caseous particles are also more abundant in the evening than in the morning—from 2.24 they increase to 2.70 per cent., but the quantity of albumen diminishes from 0.44 to 0.31. The serum is less abundant at mid-night than at noon, being 4.19 per cent. in the former case and 4.72 in the last.

## HOSPITAL PRACTICE:

METROPOLITAN AND PROVINCIAL.

### BIRMINGHAM AND MIDLAND EYE HOSPITAL.

#### DISEASE OF THE EYELID IN CHILDREN.

Under the care of J. Vose Solomon, Esq., F.R.C.S.

**CASE I.** *Phlegmonous Inflammation of the Eyelids, excited by Alveolar Irritation.* An Irish girl, 2½ years of age, came under the care of Mr. Solomon, on the 18th of November, 1852, with phlegmonous inflammation of the left eyelids; they were red, tense, and very tumid. The conjunctiva, of a bright red colour, afforded a discharge of purulent colour. The cheek on the same side was swelled. On examination of the mouth, the right canine tooth was found just above, and the left nearly through, the gum, which was much inflamed. The two upper incisors were carious; and, on taking hold of the left one with a pair of forceps, it proved to be loose, and from its side (fang?) a quantity of pus was discharged. This examination indicated the nature of the case, and the treatment of the alveolar abscess by removal of the dead and loose bone.

Several points of practical and physiological interest are presented by the above narrative. It shows the importance of examining the mouth where the cause of an ophthalmic disease is not apparent. The cases are by no means very exceptional where irritation of the dental branches of the fifth pair has, by reflex action, caused retinal blindness, or paralysis of the motor oculi nerve, with its attendant vertigo, diplopia, inability to judge of the distance of objects, and consequent uncertainty in the walk of the patient while both eyes are maintained open. When investigating such cases, we must not allow the absence of pain in a carious tooth to deceive us; as, although it may never have ached, yet, according to Mr. Solomon's experience, it may be the sole cause of reflex mischief.

As to whether the phlegmonous inflammation of the lids and the purulent conjunctivitis were referable to reflex action, or to the extension of inflammation by the continuity of a mucous surface, is a fair question for debate. The reporter is disposed to refer the symptoms to the former.

Another point deserving of notice is the late period to which the projection through the gum of the canine teeth was delayed; namely, the *thirtieth* month of the patient's age. Bell fixes their eruption as occurring between the sixteenth and twentieth month; Hunter, so late as from the twentieth to the twenty-fourth; and Tames, at from the sixteenth to the twentieth month.

The late development of the canine and the premature decay of the superior incisors are suggestive of the presence of an hereditary syphilitic taint. As regards the periostitis, which led to the formation of an abscess at the fang of the left incisor, it was an eliminative act on the part of Nature to get rid of the dead bone, which had become a foreign body in the mouth.

**CASE II.** A delicate child, 7 years of age, was attacked with catarrhal ophthalmia on December 14th, 1852. On the 15th, the upper eyelids were swollen; and on the 16th they were red. The swelling gradually increased until the 21st of December, the right suffering the most, when the patient was brought to the Eye Hospital, and the preceding description obtained from the mother. At this time, infantile purulent ophthalmia was prevalent.

On admission, there was enormous swelling of the

upper eyelids, which were of a livid red colour. They overlapped the lower lids, and projected considerably beyond them. The tumescence arched up the lid from one canthus to the other, and extended from the brow to the tarsal margin. There was considerable mucopurulent discharge. The eyelids, when everted (which was effected with difficulty), presented a concaved semicircle. The conjunctiva was of a dirty light red colour, eroded, and covered at points by false membrane (?). The sclerotic conjunctiva was slightly congested. The inferior eyelids were healthy.

The patient's constitutional power was below par. Dyspepsia and constipation were present.

The appropriate treatment of this class of cases consists in the application of collodion to the skin of the lid, injections of nitrate of silver to the conjunctiva, and the administration of tonics, etc.

CASE III. A fat infant, 2 months old, was brought to the Eye Hospital on November 18th, 1852. The upper lids were much swollen and *indurated* from infiltration. On eversion, which was performed with difficulty, the conjunctiva presented a jaundiced hue and patchy redness; it was covered by a film of lymph, which was removed with some difficulty. The surface was excoriated in places, and exuded a straw-coloured serum. The cornea of the worst eye, which had been affected seven days, was slightly turbid—opalescent. The other eye was only attacked the day before the patient's admission.

In answer to questions, the mother said she was now, as previously to her confinement, suffering from a vaginal discharge, and scalding during micturition. She had no reason for believing that any of the discharge had come into contact with her infant's eyes.

The palpebral conjunctiva was brushed over with a ten-grain solution of nitrate of silver, and small doses of calomel with quinine were ordered to be taken twice a day. Under this treatment the case did well.

### A QUESTION AS TO PATHOLOGICAL DISTINCTIONS IN CASES OF DIABETES.

By DANIEL NOBLE, M.A., M.D., Manchester.

The ordinary pathological distinctions recognised in cases of what is called diabetes, rest upon the presence or absence of sugar in the urine, when this excretion happens to be unusually abundant; and whilst the so-called *diabetes mellitus* has always been regarded as a formidable malady, *diabetes insipidus* has been considered a comparatively unimportant ailment. And, thus, the detection of sugar to any extent in the urine commonly gives rise to the most serious apprehensions. Up to within the last few years, this was unavoidably the case; because, generally, it was but when the graver constitutional symptoms of a severe form of diabetes revealed themselves, that the urine was at all tested for sugar, the presence of which was looked for as giving a definite certainty to a previous diagnosis. And as, sooner or later, excessive discharges of urine, accompanied by thirst, voracity, dry skin, emaciation and debility, were ordinarily followed by dissolution; and as these conditions of imminent danger were so often associated with the renal excretion of sugar; saccharine urine became, not unreasonably, regarded as a most formidable feature of the disease, and as one threatening death at no very distant period.

But in these days, when an examination of the urine is so universally practised in the diagnosis of disease, the presence of sugar is discovered at much earlier

stages of diabetes than was formerly the case; and this circumstance, I apprehend, should lead to a more accurate appreciation of its true pathology than when the earlier phenomena so often eluded observation. I have, myself, been induced to think that saccharine urine does not necessarily constitute that very formidable symptom in disease which it was formerly considered to be; and that, in fact, it need not be regarded as the sure precursor of that particular diabetic condition which almost invariably has a fatal termination. I will illustrate my meaning, however, by narratives of certain facts somewhat incomplete, but nevertheless showing a contrast which supplies the grounds upon which I submit a question as to a probable pathological distinction, and which at the same time furnishes an occasion for suggesting a direction to the inquiries of those whose aptitude and opportunities more especially qualify them for investigations of this kind. In this view of things, I subjoin a brief account of two cases of diabetes, representing a well-known class; and then some account of two others, the pathological significance of which, I suspect, is essentially different.

A young Greek, about 17 years of age, was brought to me some years ago, by the proprietor of a boarding school in the neighbourhood of Alderly. The complaint was that the patient had become gradually listless and weak, incompetent alike for physical exertion and mental application; and that this state of things had, for a few weeks, been almost imperceptibly making its way. On inquiry, I ascertained the existence of thirst, voracious appetite, dry skin, and large discharges of urine—symptoms which, of course, suggested the diagnosis of diabetes. I directed that the young man should not return to school, but should remain with relatives who resided in the immediate neighbourhood, intimating at the same time to the gentleman who accompanied him, that I regarded his case as very serious, and that he ought to go to bed and have constant and systematic attendance; that, if my own services were further demanded, I must be informed, and, in that case, should visit him on the following day, and would wish to see the quantity of urine voided after a given hour. It was soon afterwards intimated that I was to render him such attendance and aid as the circumstances might require, and I called upon him accordingly on the following day. I found the poor youth much weaker than on the previous day even, and ascertained that he had parted with immense quantities of urine possessing an odour and other characteristics rendering the presence of sugar very probable. I took some of it away with me, and submitted it to simple tests; it may suffice to say that the urinometer manifested a very high specific gravity, and Trommer's copper test exhibited a very large proportion of sugar. On the succeeding morning, the debility and exhaustion had very alarmingly progressed, and I gave the worst prognosis, stating that it would be agreeable to myself if they should wish to call in some other assistance—a suggestion which, it was said, should be considered. I paid an evening visit on the same day, and was told, without seeing the patient, that, in consequence of my opinion expressed in the morning, I had been superseded; that my successor, moreover, should be replaced in like manner, if he did not speedily effect an improvement; and that, in fact, doctor after doctor should be tried upon this principle. Early the following morning, however, the patient died.

Now, in this instance, there was obviously a collapse of so speedy and decided a character, that little can be said of its specific nature; the peculiar perversion of function indicative of diabetes mellitus so rapidly carried with it a destruction of all vital energy as to preclude the attempt at any special ascription of its origin and cause.

In the course of last year, a lady consulted me on account of her daughter, who for some weeks had been

losing flesh and strength; she was not more than about thirteen years of age, and had been under the care of a well-known homœopathic practitioner in this city, who did not appear to have made any definite diagnosis. On directing my attention to the young lady, my first impression was that she was labouring under some obscure form of phthisis, but a physical examination of the chest and a quiet pulse, excluded the idea; I next thought, on learning that her appetite was unusually good, of possible mesenteric disease, but I could obtain no corroboration of this notion on extending the inquiry; it was when excessive thirst was mentioned, that I thought of diabetes. The skin was dry, the appetite voracious, and the urine extraordinarily abundant; I had brought to me the same day a specimen of the urine, and found it of high specific gravity, and containing large proportions of sugar; the nature of the case was thus put beyond doubt. For about a week I saw this patient on alternate days at my own house, and she was seen once also by Sir James Bardsley. After some seeming improvement, which did not continue for more than a day or two, she began rapidly to decline, and was unable to leave her room; therefore I attended her at home, and in three days she expired—ten days from the period when she was first brought to me.

In this case, the invasion of the malady could be traced to no particular cause; it appeared that the decline in strength had shown itself slowly and insidiously; and it was only the persistence and augmentation of the debility with notable emaciation, that led the parents to regard the illness in any serious light; for, indeed, they had been encouraged by the homœopath, they said, to feel every confidence that time and his own treatment would bring about recovery. This instance, like the preceding one, constitutes a fair illustration of a class of cases familiar to practitioners and dependent upon conditions of the system but little understood,—cases which alone, probably, at no very remote date, would have had their diabetic character made out, and the general symptoms of which would alone have suggested the importance of testing the urine for sugar in order to settle the diagnosis.

But there is another class, which I proceed very briefly to exemplify. A gentleman between fifty and sixty years of age, of great mental endowment, one who had through life pursued a thoughtful and laborious career, had, for upwards of twenty years been accustomed to consult me when requiring medical aid; his ailments having generally been some feverish cold, or a slight degree of gastro-enteric irritation that rendered his digestion habitually weak. For four or five years prior to the summer of 1860, he had been deeply engaged in labours demanding much brain-work, of a kind, moreover, that involved considerable worry and anxiety. About the period just specified, he became troubled with neuralgic pains about the head, with broken sleep and gastric irritation to an unwonted extent. I was constantly urging detachment from business-cares and labours, but this recommendation was but imperfectly carried out; yet, to the extent to which it was so, the symptoms were always relieved. Late in the autumn the ailment assumed severer features; for great debility and some emaciation ensued. At this stage of affairs the patient, having a demand for his presence in London, asked if I would advise him whilst there to consult any one and whom, and I named to him a physician of well-earned distinction for his successful labours in pathological chemistry; my recommendation was acted upon, and the physician in question was seen; and, immediately on the patient's return home, my attendance was again requested. On inquiring if he had seen the London physician, and if he had, what had been said, I was told that he had done so and was glad of it, for the ailment had been found to be diabetes. I must confess, that upon hearing this statement I was somewhat startled, for there neither was nor

had been any excessive discharge of urine, nor any dryness of skin, nor any voracity; neither had the urine exhibited that greenish straw colour so often suggestive of diabetes, but, on the contrary, had displayed the same superficial characters which I had noticed for years in connexion with disordered digestion—a somewhat higher colour than usual, and lithic deposits on cooling. However, I could not doubt, after what had been said, that the urine at this time contained sugar, and, having procured a specimen, I took it to an analytical chemist, that it might be quantitatively as well as qualitatively examined. It was found to contain about eight per cent of sugar, and the specific gravity was 1.031. I had already said to the patient that, although the urine should contain sugar, I did not think it quite correct that the case should be designated diabetes, if by the term was understood that grave form of it, which, undermining by degrees the forces of life, terminated in death by a sort of gradual decline; and that, indeed, I wished him to rid his mind of such a notion, as being, at least in my judgment, not only not true, but calculated in itself to do him serious physical mischief. I had explained to him, moreover, that it had of late years been discovered that mental irritation, by its action on the brain, might give rise to saccharine urine, and that this phenomenon was not always of that momentous and fatal significance which the popular estimation of diabetes might lead him to think. However, he had received from his metropolitan adviser both medicinal and dietetic prescriptions—all *secundum artem*, and these, I said, he must in fairness carry out *au pied de la lettre*; I let him understand, nevertheless, that I gave preference to my own practical views, which involved detachment from harassing occupation and thoughts, change of air and recreative amusement, with such medicines and diet as his own particular experience might suggest to be the best calculated to restore the integrity of his digestive functions. After a trial of what I will call the systematic treatment for about a fortnight, he was obliged to give it up alike in its medicinal and dietetic items, for both appetite and digestion became still weaker; and, altogether, he was put more and more out of order; but, all this time, neither the skin nor the quantity of urine gave any of the usual indications of advance in the direction of diabetes as ordinarily understood. Early in 1861, all *system* of treatment was laid aside, my own more general views were carried out, and he began to improve; the quantity of sugar in the urine and the specific gravity also were diminished, varying however from time to time. In a few weeks the percentage of sugar was reduced to five, when, for what I deemed to be good and sufficient reasons, the urine ceased to be examined; the patient had possessed himself of an urinometer and was in the habit of using it himself; and in this way, I thought, he was exercising a prejudicial influence upon his physical condition by unduly fixing his attention upon it; therefore, subordinating my scientific interest in the case to anxiety for the patient's recovery, I urged that he no longer notice the urine, that he forget it, and, so long as he continued to improve, neither make nor have made any more examinations of this excretion. Through the spring the improvement went gradually on, appetite and digestion better, and the strength increased; by the summer, he might almost be regarded as well. In the month of July, however, he had a most serious attack of summer-cholera which, after some days very severe suffering, abated; I only saw him once during this illness as it occurred upwards of forty miles from Manchester; but from what I did see, and from the account furnished by the local surgeon, I am enabled to describe it as most enervating in its effects, and he was for some time much shattered by it; still, neither at the time, nor during the ensuing convalescence, was there any manifestation of the constitutional symptoms of diabetes. This gentleman when sufficiently well during the autumn went to Mal-

vern, sanguine from what he had been told that the water-treatment would invigorate him and perfect his cure; and, for my own part, recognising the benefit to arise from this very mental prepossession, I raised no objection; and, certainly, on his return home, towards the end of the year, he appeared quite well. For reasons, however, already stated, I neither made nor procured any chemical examination of the urine. During the spring of the present year, the patient had another very severe break-down, in the old way and from the old causes,—head-ache and functional disturbance of the stomach from excessive brain-work and irregular diet; still no suppression of perspiration, no excess in the quantity of urine, no voracity. Perfect recovery followed. At this time the gentleman is in excellent condition, looking perfectly well and cheerful, and is said by his friends to have a more healthful appearance than he has presented for some years.

A gentleman of my acquaintance, of high intellectual endowment, and, moreover, of great sensitiveness of disposition, has for the last seven or eight years had saccharine urine—a symptom which ensued upon much anxious mental effort. As he is a resident at a considerable distance, I cannot exactly speak of this gentleman as my patient, although on several occasions I have had conversations with him on the subject of this particular derangement of his health. I think it was about the year 1854 or 1855 that sugar was first discovered in the urine, but he had for many years had an imperfect digestion, evidenced very often by lithic deposits, and he had been a bad sleeper. In this case, there has been none of that steady progress in a downward direction so commonly happening when there is saccharine urine. From the time of its detection to the present there have been several attacks of illness, and on two occasions the patient had been all but given over. I saw him about three years ago labouring under irritable heart as the chief malady; he was in bed and much exhausted, so much so, indeed, that his friends, having regard to the diabetes, scarcely expected that he would rally; yet, at this time the specific gravity of the urine was not high, below 1,030 I think. The gloomy forebodings were not realised, and recovery took place, enabling him to fulfil important and responsible duties. In this instance, there was, for the most part, a somewhat inordinate appetite, but not any particular dryness of skin nor any great excess of urine. I select for illustration a case, with which I am but imperfectly acquainted however, mainly because the connexion in degree between mental wear and tear and saccharine urine was on several occasions quite notable; for example, about four months ago, the patient was abroad accompanied by an intimate friend, from whom I had shortly afterwards the information that, during this absence from home, circumstances occurred to produce great stress of mind, breaking down the health for a brief period; that, apparently in consequence, the diabetic symptoms became very much aggravated, the specific gravity of the urine running up to 1,051 from 1,025. On the enjoyment of quiet and the restoration of mental calm, the *status quo* was very speedily recovered; and, since this occurrence, the patient has been better than for a long time before. Indeed, a gentleman well acquainted with him, writing about a month ago to me on another subject, refers to our common friend as follows: "He keeps well; I suppose there never was known such a case."

I think there can be no doubt that the class of facts, very imperfectly exemplified by the preceding accounts, demand the inference that some causal relation subsists between certain pathological states of the brain and the excretion of sugar by the kidneys; showing, as it would appear, that mental perturbation is one of the first links in the chain of diabetic phenomena, and showing, moreover, that the degree of mischief exhibits some correspondence with the intensity of the presumed cause. Indeed, so

obvious is the relation in question, that it has been suggested by some, that diabetes mellitus is essentially of encephalic origin; and, certainly, if pathological distinctions cannot be established, there is much evidence that may be cited in maintenance of some such thesis. The well-known experiments of Claude Bernard, repeated and confirmed by Dr. Pavy in this country, furnish no little plausibility to the doctrine; they shew that saccharine urine can be artificially produced by mechanical irritation of the floor of the fourth cerebral ventricle. And other experimental lesions of the nervous system, moreover, have been found to produce diabetic symptoms since the one first practised by M. Bernard. Ordinary brain-disease will sometimes develop for a time a saccharine condition of the urine. The case of the late Mr. Hopwood, which attained so much notoriety in the year 1855, on a trial affecting the validity of a will, supplies an excellent illustration of this position. In 1840, five years before this gentleman's death, it appeared from the evidence given on the trial by his very intelligent medical attendant, Mr. Abraham Wood, of Rochdale, that at the period mentioned he began to suffer in his head, complaining of pain, somnolence, and intolerance of light—symptoms attributed by Mr. Wood to congestion of the brain, and which later on were followed by paralysis and dementia; "he had also another ailment", said Mr. Wood, "an affection of the kidneys". On cross-examination, he was told to say what this affection was, and he stated that it was "diabetes mellitus", and then that this was recovered from in ten days or a fortnight. Hereupon, Sir Fred. Thesiger, the cross-examining counsel, seemed to think that he had got hold of a good point for weakening the force of Mr. Wood's evidence, for, echoing the general popular impression concerning the necessary fatality of diabetes, he observed: "That (diabetes mellitus) is the incurable kind, is it not?" To this interrogatory Mr. Wood very sensibly replied, "It depends upon the cause." Sir Frederick, however, pursued the topic, resting upon the position that the ailment in question could never be recovered from, and that Mr. Wood did not know what he was about; but that gentleman was quite a match for the clever counsel, stating that he had not merely been led to the diagnosis by the general symptoms, but that he had tested the urine and detected the presence of sugar.

Now, the question which I would propose for this evening's discussion, and the question to which all that has preceded is introductory, is this: Is it possible to establish pathological distinctions in cases of diabetes, according to their *origin*, the *course of the symptoms*, and their *curability*—characteristics which, under many circumstances, supply the basis of such distinctions? In all these particulars, there would seem to be a wide difference between such instances as those last cited and those which I sketched in an earlier portion of this paper, the presence of sugar in the urine being almost the only phenomenon common to the two sets. May we not expect that, in further prosecution of our investigations in this direction, we may be enabled to determine distinctions in cases exhibiting sugar in the urine, just as now we can and do, but could not formerly, in the analogous instances of albumen in the urine? When Dr. Bright demonstrated the pathological connection between granular kidney and albuminuria, it was for some time afterwards regarded as constant; and albuminous urine was consequently regarded as possessing a much graver significance in all cases than it is now known to have in many; for, at the present day, this symptom is known to be expressive of pathological states various in their kind, and involving great differences alike in their origin, course, and curability; hence, we estimate the general character of albuminuria, not by the amount of albumen in the urine, but by the morbid causes which have brought this irregular excretion about. Is it not practicable, then, to establish, or to discover, in like manner, scientific as

well as practical distinctions in cases of diabetes? I would venture, myself, to express the conviction that modern researches are tending in this direction; and it is to stimulate attention to this view of the subject, that I have brought forward the question upon the present occasion, not, I need hardly say, in the form of a clinical contribution scientifically complete, but rather in that of an exposition of a course of thought initiated by the incidents of a casual experience.

#### CHRONIC INFLAMMATION OF THE OS AND CERVIX UTERI.

By GEORGE P. GOLDSMITH, Esq., Bedford.

[Read October 23rd, 1862.]

CHRONIC inflammation of the os and cervix uteri is one of a group of disorders, very common, indeed, in their occurrence, but to which comparatively few, I think, pay much attention during the time in which they are attending the medical practice of the hospitals. One reason for this neglect is, perhaps, to be found in the fact that, although it entails severe and long continued suffering, this is not a fatal disease, and we do not therefore frequently have an opportunity of examining the morbid changes produced by it; and, as it does not generally wholly incapacitate the patient from following her usual avocations, we do not often see her as "in-patient."

I must here, at the outset, state that the few observations I have to offer will be far from forming anything like a complete thesis upon this subject, but will merely embody the most prominent impressions made upon my own mind, while daily witnessing the complaint in a considerable number of cases. When I first undertook the duties of my position in the hospital, I had heard and read of the disease, but imagined it to be a rare affection, with which I should probably hardly ever meet; and I confess I was both astonished at, and unprepared for, the frequency with which it presented itself.

When we consider the important part played by the uterine functions, their periodic recurrence after intervals of comparative inactivity, and the complicated character of the structures by which they are maintained, namely, an organ comprising a serous, parenchymatous or muscular, mucous and glandular or follicular apparatus, we shall neither be surprised at the frequency with which some of these functions are liable to disturbance, nor at the gravity of the results attending it. The greater frequency of congestive diseases of the cervix uteri over those of the fundus, may be partly explained by the anatomical difference of the vascular return of the venous blood in these parts; the blood from the body and fundus uteri being conveyed back chiefly through the ovarian veins, passing directly to the vena cava, or a primary branch of it; while the blood from the cervix is returned by the uterine and hypogastric plexuses, branches contributing to form the internal iliac, and more liable to congestion from their proximity to the rectum and bladder, organs continually becoming distended, and thus, to some extent at least, exercising pressure on the cervix.

A patient, during the period of life when the sexual functions are active, comes complaining of general ill health and exhaustion; the complexion being pale, and, as is frequently the case, of a peculiar dusky hue, quite distinct from the cachectic sallowness of carcinoma, looking more smoky, if the expression may be allowed, and often presenting well marked dark areolæ round the eyes, so expressive of an exhausted and tried condition

of the system. The pulse is generally of low power and increased in frequency; while the patient's whole manner is often nervous, excited, or irritable, the depression of spirits being sometimes extreme, and the ordinary symptoms of chronic hysteria more or less present. The patient seems bereft of the feminine fortitude we so much admire in her sex when suffering from disease in general, and readily enters into a long and emphatic description of her sufferings, foisting it by a shower of tears, and evincing much fretfulness and impatience at one's close questions. There is not, as a general rule, much disturbance of stomach; we do not meet with that distressing nausea and vomiting so commonly accompanying the earlier stages of schirrus; but there is frequently dyspepsia and flatulence; the bowels being for the most part costive, and often refusing altogether to act without the continual use of purgatives.

*Leucorrhœa* is generally of early occurrence; and this discharge, so commonly present in most uterine ailments, presents in this disorder somewhat peculiar characters, arising from the anatomical structure of the part in which it is situated. In the cervical canal, the mucous membrane is thrown into longitudinal rugæ, an appearance forming the "arbor vitæ uterina"; in these folds the membrane is studded with large mucous crypts, called the *glandulæ nabothi*; these being stimulated to undue action, secrete a thick gelatinous mucus, as after the stimulus of impregnation; but, instead of remaining in the cervix and closing the canal, these pledgets are ever and anon discharged with the other matters thrown off by the uterus. I have had these masses shown me by patients, who have regarded this symptom with alarm. Of course the thin white vaginal discharge often accompanies; but, as far as I am aware, the above mentioned secretion is characteristic of this affection.

An almost constant and important symptom, also, is *menorrhagia*. The patient complains that the menstrual periods are accompanied by a more profuse discharge than natural, and that the interval between each period becomes gradually shorter, so that, in the worst cases, they say that there is an almost constant draining.

But the symptom most prominent, and that which, with the last mentioned, especially leads the patient to apply for relief, is *pain* of a peculiar heavy, dull, aching character, referred to the upper part of the sacrum, sometimes extending round the pelvis and into the groins. This I have found, in the cases I have treated, to be almost continually present; not always in the same degree, but generally amounting to a settled uneasiness, subject to occasional exacerbations, especially upon exertion.

The *internal examination* reveals an enlarged, tumified, and hypertrophied state of the os; the lips of which are frequently everted, leaving the aperture large and gaping, so as easily to admit of the introduction of the tip of the finger, while the body of the uterus is slightly increased in size and weight, as may be estimated by poising it on the finger. The engorgement of the os varies much in extent and character. Sometimes there is so much hardness and irregularity, that the diagnosis between this condition and the first change produced by carcinoma is attended at first with some doubt. To this point, as being one of great practical importance, I shall again presently revert.

The frequency of ulceration as an attendant upon this disease has been attested by so many observers of undoubted character and authority, that, although it is still disputed by some, for whom we entertain all respect, yet we cannot entertain any doubt as to the fact. These ulcerations are often mere excoriations of the epithelial layer, and can hardly be detected without the aid of the speculum, even by those most skilled in digital examinations: that these do exist, however, and that they are the proximate causes of many of the symptoms, such as *leucorrhœa* and *menorrhagia*, which attract

the patient's notice, and compel her to apply for advice, we cannot but be satisfied.

Another kind of ulcer, perhaps not so common, but more easily detected by the simple touch, is that which presents a granular surface, more or less rough, and attended by much the same symptoms as the former variety; the great difference being, that these are really erosions or ulcerations in the substance of the lips, which are granulating, and they therefore readily bleed upon being touched.

I have no doubt that this condition has existed in many more cases than those wherein I have been able to satisfy myself as to its presence; having frequently suspected it, from the pain produced at a certain circumscribed spot by the pressure of the finger.

As to the *causes* of this affection, they are very obscure, and I cannot say much about them. Sometimes, I have no doubt, it is primarily induced by the abuse of the sexual functions, the uterus being kept in a constantly irritated and congested state, which the constant repetition of the exciting cause maintains, and prevents the organ from righting itself. This is a condition very commonly observable among prostitutes, and occasionally also among married women.

It is a question that I have often revolved in my own mind, whether abortion is more frequently a cause or a consequence of this disease. Certain it is that, in not a few of the cases that have come under my notice, the patients have referred their first appreciable loss of health to a miscarriage, from which they have never entirely recovered. It is also equally beyond a doubt that, while this condition of cervix does not absolutely prevent conception from taking place, it nevertheless renders it highly improbable; and should it notwithstanding transpire, almost certainly ensures the premature expulsion of the fetus.

One important point, to which I would draw special attention, is, with what other morbid states we are likely to confound that which we have been considering. It is a matter of every day observation that, when the processes are normal, the uterus after parturition should contract, so as to render the organ about the size of an infant's head, after which it gradually undergoes a process of interstitial degeneration and absorption, coincidently with a discharge from the lining membrane, whereby, after a few weeks, it assumes nearly the same bulk and dimensions as before impregnation.

Now it sometimes happens that, from some cause or other, this process of disintegration and removal is arrested or retarded; so that, if an examination be made, the lips and cervix are found in a condition very similar in many respects to that which I have been attempting to describe.

The distinction, however, lies in the fact, that in defective involution of the recently gravid uterus, the *body* of the organ is also enlarged considerably beyond the natural size, while in chronic inflammation of the cervix, the body is generally the subject of only trifling enlargement.

There is a condition sometimes to be met with, in which the cervix uteri is the seat of constant uneasiness, but which at periodic intervals, gives place to paroxysms of excruciating pain; this is the "irritable uterus," described in a monograph by Dr. Gooch, which occurs chiefly in young women, and consists of nothing more or less than neuralgia of the organ; a rare affection, which from the constant wearing uneasiness, might possibly at first be confounded with this chronic inflammation. It is, however, distinguished by several marks; for instance, in the "irritable uterus," there is no appreciable change of structure, while the suddenness, violence, and, above all, the periodic recurrence of the exacerbations without inflammatory symptoms, render the disease easy of diagnosis.

But the most frequent source of error arises from the

extreme similarity which often exists between the condition of uterus presented by the disease we are considering, and that which we so frequently meet with in the early stage of scirrhus, before the occurrence of ulceration or much disorganisation, when the cervix is infiltrated by the dense, hard, unyielding tissue, but too familiar to us; and perhaps the best means of illustrating the difficulty which sometimes exists in arriving at once at a satisfactory decision, will be to read a brief abstract from the histories of two cases which were under observation about the same time.

M. D., aged 28, was admitted into the Burton Ward, July 10th, 1861. She was a strong and tolerably healthy looking person, but with depressed manner and dusky complexion. She was a servant, and unmarried, and had a child nine years since. The catamenia always recurred at the regular periods, and she always enjoyed good health until six months ago, when she suffered from pain in the right inguinal region; this was relieved by treatment, and she continued pretty well until two months ago, at which time she began to suffer from a hot burning pain, referred to the sacral region, and passing round the pelvis. She had had a yellow inodorous discharge, not so profuse at present as it had been. She had been under treatment at the Brixton Dispensary, the diagnosis of the case being written on the dispensary paper, "scirrhus uteri." She had been examined with the speculum by a leading surgeon-accoucheur, who said that she had ulcerated womb.

Dr. Robert Lee examined, and found the anterior lip of the os uteri hard, enlarged, and irregular; he said that he could not at present decide whether this was due to carcinoma or not. A few days afterwards, on repeating the examination, he found that much of the hardness previously noticed, had disappeared. She soon left the hospital, continuing for some time under my care as out-patient, and improved so much that she soon asked permission to marry; the symptoms being all relieved.

The second case is that of A. M., aged 42, married fifteen years, and having had three children. The patient though stout and in good condition, bore a pale and unhealthy appearance, with intensely dark areolæ round the eyes. She enjoyed good health until two years ago, when the catamenia, which had hitherto been regular, gave place to profuse menorrhagia, accompanied with severe pain all round the pelvis. She recovered partially for a time, but the symptoms continued in a mitigated degree until three weeks before her admission, when they returned with all their former severity. She was seen by a physician-accoucheur of much experience, and he pronounced her to be labouring under carcinoma uteri. When, however, Dr. Robert Lee examined, he found the os hard and irregular, but decided at once that the disease was not malignant. She improved much while in the hospital, and soon left it convalescent.

In these cases (and many similar ones might be quoted), the only symptom wanting to complete the history of scirrhus, was the offensive discharge which almost invariably marks the progress of that terrible scourge; but there were in each case, circumstances that might have excited doubts of the correctness of the diagnosis which had been formed. The age of the first patient, only 23 years, made it unlikely that she should be the subject of scirrhus uteri, although while she was under treatment another patient of mine died of it at the age of 32. And, in the second case, the long period during which the symptoms had existed, induced the suspicion that had the disease been malignant it would have run its course more speedily.

Whatever doubt we may entertain as to the nature of the case when we first see it, is however soon dispelled when the patient has been a little while under observation. Rest and treatment generally make so much improvement in the case of chronic inflammation as to enable us quickly to determine its nature. The unnatural

hardness of the os gradually disappears; the pain in the back is relieved; the engorged and infiltrated tissue of the cervix is relieved by the absorption and removal of the morbid matter to which its enlargement was due, and it shows evident signs of responding to treatment, though to get rid of it altogether is a task tedious enough.

The carcinomatous cervix, on the other hand, gets perhaps slowly, but surely worse; hæmorrhage and ulceration, destruction of tissue, pain, and the cancerous cachexia, pursue their too well known and fatal course.

It is with considerable diffidence that, so young as I am in my subject, I venture to say a few words on that which is the object of all our observation and research, namely the *treatment* of this troublesome malady.

In the first place, *absolute repose* of the inflamed tissue is one of the first principles of our ordinary rules of treatment in diseases of other parts; and therefore, everything tending to promote or provoke irritation and congestion is to be carefully avoided, when possible; it is expedient to enjoin "change of air," in other words, separation from the husband's society. Sometimes, however, intercourse is so painful that it has been already discontinued, and in one well marked case, it was this symptom which led the patient to apply for advice.

As the bowels are generally costive, I have found it serviceable to commence the treatment by a dose of blue pill or calomel, with an active vegetable cathartic, as colocynth; and subsequently give, two or three times a week, a gentle stimulant to the sluggish intestine in the shape of ten grains of the aloes and myrrh pill, or the compound rhubarb pill. If there be no febrile disturbance of the system, and the induration be considerable, I generally prescribe a drachm of solution of bichloride (*Pharmacopœia*) of mercury, in an ounce and a half of decoction of cinchona twice a day; or four grains of iodide of potassium, in an ounce and a half of decoction of cinchona or infusion of gentian three times a day.

If there be any hardness about the pulse, I generally set the kidneys acting by salines and mild alkaline remedies, before commencing with the more active constitutional sorbefacients. Sooner or later, however, tonics, in some form or other, will be found necessary.

But as the chief anxiety on the patient's part is to get relief for the symptom which distresses her most, viz., the pain in the back, we must do something for this; and I have for this purpose, extensively and successfully used a liniment, at once simple and efficacious, and really valuable. I got it from Dr. West's book on the *Diseases of Women*. It is formed of a drachm of croton oil and eleven drachms of camphor liniment. The relief afforded by this application is in many cases truly surprising. I have been told that as soon as the skin became sore, the deep-seated wearing pain disappeared; and when the cuticle is renewed, another slight dabbling of the surface continues the effect. With regard to local applications to the ulcers of the cervix I can say nothing, having had no experience of them; but astringent and soothing injections, such as the lead lotion, the liquor aluminis compositus, and the decoction of oak-bark, are of the greatest use in toning and bracing up the diseased parts; checking the leucorrhœa; correcting and removing irritating discharges, and promoting the healing of the ulcers where they exist.

The most severe, however, of these means are mild indeed by the side of the heroic and dashing treatment introduced by some of our energetic brethren across the Atlantic.

I some time ago came across a pamphlet by Dr. Marion Sims, surgeon to the Women's Hospital, at New York. He cuts the Gordian knot literally enough, and removes the disease root and branch by "amputation of the cervix uteri," which is the title of his little brochure. According to his account, the operation appears to be

productive of but little constitutional disturbance, and his process is, to cut straight through the cervix with a pair of scissors, as producing less hæmorrhage than the knife, in a kind of *écraseur* fashion; and then covering the cut surface of the stump, if I may call it such, with vaginal tissue, which is retained in position by sutures, until union by first intention has taken place; this is Dr. Sims' improvement; as previously the wound used to be left to heal by granulation, a process occupying several months, and attended by a good deal of suffering and inconvenience. Dr. Sims speaks very favourably of the good results which he has been able to obtain by this operation, which, however, will hardly gain ground in British practice, as it would be reprobated by the heads of the profession, and could hardly be submitted to by English ladies.

## BATH AND BRISTOL BRANCH.

ON DISEASE OF THE ASTRAGALO-CALCANEAL JOINT PRODUCED BY INJURY.

By R. W. COE, F.R.C.S.E., Senior Surgeon to the Bristol General Hospital.

[Read April 29th, 1862.]

THE diseases of the larger joints have been successfully studied by some of our best surgeons; whilst those of the smaller ones, as of the foot and hand, have met with less attention; and but little care has been bestowed, in the discrimination of the particular joint or bone affected.

Indeed, up to the present time, it has appeared sufficiently accurate for practical purposes, to characterise all the affections of the tarsal and carpal bones and joints, however various their origin, course, and termination, by the generic term, disease of the tarsus or carpus; occasionally, however, qualifying the vague appellation by the use of the words strumous, syphilitic, gouty, etc.

From my observation, during the last ten years, of the diseases of the tarsus, more especially of those following upon slight blows or strains, I may safely assert that the astragalo-calcaneal joint is more frequently affected than either of the other tarsal joints; that, from the functions and anatomical character of the astragalo-calcaneal articulation, the bones entering into its composition very frequently and early participate in its diseases; that from its proximity to the ankle-joint, the latter articulation is generally looked upon as the seat of the mischief, which is really situated in the astragalo-calcaneal joint; that the signs of the beginning of mischief in the astragalo-calcaneal joint are very early to be appreciated; that a careful attention to the history of the cases I shall relate, and the results of the treatment had recourse to, point out what course should be adopted in their management; and finally, that a consideration of the anatomy and function of the astragalo-calcaneal joint, more especially when compared with those of the ankle-joint, renders it very probable that the view I shall bring before you of the affections of the former is a correct one.

The following cases are related not in their chronological order, but in the one best fitted to illustrate the history of the disease.

CASE I. (From the notes of my dresser, Mr. James.) Elizabeth Brown, aged 23, married, was admitted into Ladies' Ward of the Bristol General Hospital, on November 2nd, 1861.

*History.* Up to July 1861, she was servant at a public house, where she had to walk a great deal, and was in the habit, in the performance of her duties, of frequently jumping from a height of three steps; she had had weakness of the right foot for about eight months, also swelling, and a very slight aching pain sometimes.

*Present Appearance and Condition.* There was a good deal of swelling and puffiness on both sides of the foot,

just over the line of junction of the astragalus and calcaneum, accompanied with increase of temperature; much pain on pressure of the swelling; great pain on seizing the astragalus firmly in one hand, and moving the calcaneum with the other; or on striking the heel sharply with the hand, so as to press the calcaneum against the astragalus. She had no pain on moving the ankle-joint; nor was there any swelling except over the line mentioned.

The treatment consisted in perfect rest from November 2nd, 1861, to February 10th, 1862.

December 14th, 1861. The increase of temperature and swelling still continuing, two leeches were applied below each malleolus, and iodide of potassium was given internally.

December 16th. The leeches were repeated.

December 24th. The swelling was very much diminished. The leeches were again applied.

February 10th, 1862. No discomfort remained; the swelling and increased temperature were entirely gone. The foot and leg were strapped with soap plaster from the toes to the knee, and bandaged. She was made an out-patient; and requested, when desirous of walking, to do so either with the knee resting on a wooden leg, or with the help of crutches, and not on any account to rest the weight of the body on the affected foot.

I have seen her recently, and am enabled to report her well.

This case was specially interesting to me, because it gave an illustration of a condition, which I felt pretty certain, must have preceded those states of the joint with which I was more familiar. I would beg to point out the line of swelling immediately beneath the malleoli, yet nearer the outer than inner one; the extension of the outer swelling forwards to the hollow beneath the neck of the astragalus; the extension of the inner swelling backwards, so as to bulge out the spine in front of the tendo Achillis; the pain produced by attempting to move the calcaneum on the astragalus; or by pressing on the heel, and the entire freedom from swelling and pain in the ankle-joint.

CASE II. John Bilby, aged 32, collier, was admitted into Eaton Ward of Bristol General Hospital, February 24th, 1859.

*History.* He sprained his left foot about three years since, by slipping off a metal rail underground. He worked up to seventeen weeks since. He had not any treatment for his foot until November 5th, 1858, when he went into the infirmary, which he left in seven weeks (on account of his wife's illness), his foot being then worse.

*Present Appearance.* He was thin and pale. The left ankle was swollen. The swelling was not in the ankle-joint, but in a line corresponding to the astragalocalcaneal articulation; it projected on each side below the corresponding malleoli, also posteriorly above the projecting part of the calcaneum, thrusting out the tendo Achillis. On grasping the calcaneum and attempting to move it on the astragalus, a grating was felt, as if the bones were rough; there was sufficient motion to give the idea of weakening, if not entire destruction of the interosseous astragalocalcaneal ligament. He could move his ankle-joint without pain; but he felt pain when he put his foot to the ground. The pain complained of was exactly in the situation of the astragalocalcaneal joint.

March 2nd, 1859. I made an incision, beginning a little below and in front of the external malleolus, carried it under the external malleolus at the distance of an inch, and brought it up to the inside of the tendo Achillis, an inch above the insertion of the latter. A dépôt of pus in the neighbourhood of the tendon was opened; a probe could be passed deep into the astragalocalcaneal joint and rough bone felt. I dissected on, and exposed the joint, and found it clearly diseased; and determined, if

possible, to remove the articular surface of the os calcis. I made a second incision, one inch and a half in length, across the dorsum of the foot, which fell on the anterior extremity of the first, so as to enable me to divide any fibres of the interosseous ligament that might be remaining.

I dissected up the side flap for a short distance, and opened into the articulation without injuring the peroneal tendons. I found the articular surface, especially of the calcis roughened, and a number of white soft granulations between the bones; these were seen especially in front. I succeeded, partly with Hey's saw and partly with the chisel and gouge, in removing the articular surface of the calcis, and eventually obtained a moderately smooth surface. The bones were drawn into position by the tendons; the flap was fastened down by sutures; and the limb laid upon its outer side.

For some time the case promised fairly; indeed, I think might eventually have recovered; but the man became impatient, as his wife and child depended solely on himself, and he begged to have his foot removed; to which, much to my annoyance, I was obliged to accede.

I removed his foot at the ankle-joint; he quickly made a good recovery.

When this man came under treatment, I had determined that ankylosis of the joint was the termination to be sought for in this disease, when the mischief had advanced to suppuration; and that in the majority of cases this result was hindered or prevented by the difficulties in the way of the escape of the products of inflammation, and of the *débris* of the broken down tissues.

I thought that if I gave free exit to those products, and in addition a new surface to the bones, I might possibly succeed in bringing about this desirable result. In the present instance, I now believe, that too much was attempted; it would have been better merely to have made free openings into the articulation for the escape of morbid products, leaving to nature the preparation of the bony surfaces, especially as they were smoothed with so much difficulty.

CASE III. The succeeding case, which was admitted into the Bristol General Hospital, under the care of my colleague Mr. Marshall, is important as shewing what should be sought for in the treatment of the disease.

I am indebted to Mr. Marshall for notes of this patient. "John Daniel, aged 22, was admitted into the Bristol General Hospital, November 25, 1861, with disease of the ankle-joint of the left leg. He stated that he had been more or less troubled with his ankle since he was 8 years old, when he was a patient at the Infirmary; the ankle being then swollen and painful; that he remained there several weeks; leaving unrelieved for Clevedon, when he continued to get worse; that an abscess ultimately formed in the neighbourhood of the joint, which broke, and after discharging freely for some weeks, healed up; and that then he felt much better. The improvement did not, however, continue long; and some months subsequently, he was again admitted into the Infirmary, when he remained several weeks, and then left relieved and able to return to work. Ever since this period, he had been compelled to lay up at frequent intervals, on account of abscesses forming and breaking about the ankle. For five months previously to his admission into the hospital, he had suffered an unusual amount of pain, and the discharge had been very profuse. When he was admitted there was considerable swelling on both sides of the joint, but little or none over its anterior aspect. There were two sinuses on the inner side of the joint, one a little below, and the other below and posterior to the internal malleolus. A probe passed into either of the two sinuses, and readily reached diseased bone."

Thus far Mr. Marshall's report. I saw the case with him in the hospital; and stated that I believed it origin-

ally to have been disease of the astragalo-calcaneal joint, for the following reasons: from the form of the swelling; from the sinuses leading to bone in the situation of the joint itself; and finally, from the fact of the true ankle-joint having been free from disease up to a very late period.

It was thought advisable to remove the limb at the ankle, which was done by Mr. Marshall, on November 28th, 1861. He kindly allowed me to examine the amputated foot. I found the astragalus and calcis nearly everywhere firmly ankylosed, and the strong interosseous membrane absorbed; and thus an almost perfect cure of the original disease accomplished; but, unfortunately, a small portion of the joint in front of the inner malleolus had not been able to free itself easily of its purulent secretion. This diseased part was in close relation with the synovial membrane of the ankle-joint, which at last became affected, though nature had been struggling manfully on for fourteen years for a successful result, which, in truth, was just within its reach.

The history of this case extending over so long a period of time; the ankle-joint, though so near the disease, remaining so long unaffected, taken in connection with the appearance of the amputated part, must shew clearly where the seat of the disease had been.

Had the case been my own, I confess I should have been inclined to have tried some measure short of amputation of the foot, bearing in mind the reason of the failure in the last case read.

CASE IV. I am obliged to give this case from memory, being unable to find the written notes. Mary Ann Browning, a middle-aged woman, was admitted under my care at the Old Guinea Street Hospital, for disease of the right astragalo-calcaneal articulation and of the bones forming the joint, the ankle-joint not being affected. There was the same character of swelling as in the former cases; the same pain on moving the calcis on the astragalus; the same uneasiness on pressing up the heel, with sinuses leading into the joint and on to the exposed and diseased surfaces of the adjoining bones, which were involved, apparently, to a considerable extent.

I removed from this patient both the astragalus and the os calcis; and though she was a long time recovering, from her health having become seriously affected in consequence of a large chronic abscess which formed in the opposite thigh some time after the operation, she ultimately did get well with an useful and shapely foot.

I received a letter of thanks from her last November, telling me how well able she was to perform her household duties. Before preparing this communication, a friend kindly saw her for me and reported very favourably of her condition. This is only the second recorded case in which both these bones have been removed. The appearance of the removed part confirmed the above diagnosis.

REMARKS. I have chosen the four foregoing cases to bring under your notice, because they appeared to me to well illustrate the symptoms and natural progress of the disease, and to afford hints for a more successful treatment than that hitherto adopted; a treatment not new in the management of diseased joints, but to a certain extent new in its application to the particular articulation I have been speaking of. It admits of division into five degrees of severity, according to the advances made by the disease.

1. Whilst the joint (and by the term joint is meant, not only the two synovial sacs between the bones, but also the interosseous ligament) is simply irritated or inflamed, compel perfect rest through a long period of time—say months—and the occasional application of leeches or warm soothing applications; and when the recovery is sufficiently advanced to allow the patient to leave the bed, insist upon the foot being relieved from the weight of the body for many weeks or months, as by

the use of a wooden leg or of crutches. This plan is to be used in every case.

2. When there is evidence of the presence of pus in the articulation without any external opening, or when an external opening exists leading down to the joint or bare bone, but not affording a free exit to the discharge, then open the joint by as free incisions as possible, in hope that, by relieving the parts from all irritation, they may recover. The great probability of this occurring being demonstrated by Case III.

3. When the disease has made still further progress, and the bones become so involved as to render it unlikely that the last plan would answer; or after the failure of that treatment; then I would very strongly advocate the propriety of removing the os calcis; thus giving the under surface of the astragalus the best chance of recovery, and preserving to the patient a most useful and shapely foot.

4. When both bones are apparently immediately affected, I would advise their removal, as also that of the projecting malleoli of the ankle-joint. So far as regards the disease, this proceeding is as completely eliminative as amputation at the ankle-joint itself, but has the great advantage of preserving a very useful and assuredly a more slightly extremity than the stump of an amputation.

5. When, from the long continuance of the disease, many of the neighbouring joints and bones are affected, as the ankle-joint and bones and joints of the tarsus; or when, superadded to the original disease, there is a well marked constitutional or scrofulous diathesis, of such a nature or to such an extent as to render it probable that the restorative powers of the patient would not be able to bring to a favourable result the designs of the surgeons in some of the foregoing plans; then, and not till then, do I think amputation of the ankle is justified.

As regards the frequency of the disease, it is accounted for by the accidents to which the joint is liable, taken in connection with its structure and functions. Flexion and extension of the foot are performed at the ankle-joint, which admits of no other motion; the strong ligaments which connect the tibia and fibula with the bones of the foot, pass on the inside from the tibia almost entirely to the astragalus and scaphoid bones, and on the outside from the fibula to the astragalus, though it is true that some fibres pass down from each malleolus to the os calcis; but they are few in number, though sufficiently strong to assist to hold the os calcis in position. The movements of abduction and adduction of the foot are performed entirely at the astragalo-calcaneal articulation.

The structure of the joint may be briefly stated as consisting of two synovial sacs covering opposed surfaces of bone so shaped as to admit of the movements of adduction and abduction; and also of two strong interosseous ligaments placed diagonally between the bones and separating the two synovial sacs from one another; the articulation being further strengthened by those portions of the internal and external lateral ligaments of the ankle-joint which pass between the malleoli and os calcis.

Now, what happens in forcible adduction of the foot? The interosseous ligament is put on the stretch, the astragalus is thrust against the outer malleolus; the ligaments of the ankle-joint are not then affected, but the shaft of the fibula is; and if the adduction be continued, or if it have taken place forcibly and suddenly, the fibula breaks; the tension, up to the time of the snapping of the fibula, is entirely borne by the interosseous ligament.

The same order of events occurs in forcible and quick abduction; when, however, the inner malleolus, as well as the fibula, is liable to be broken.

But if, in this class of accident, the fibula should not

give way, then the whole or greater part of the strain falls upon the interosseous ligament between the os calcis and astragalus, causing stretching or partial rupture of the ligament.

Thus are sown the seeds of the future irritation and inflammation of the joint, which bring about the grave consequences that so frequently necessitate operative interference; consequences all the more likely to occur from the sufferer thinking he has only had a strain which need not require any great care.

I have purposely left out of consideration in this communication all reference to constitutional predisposition, thinking to simplify the matter, by treating only of those cases in which the local ailment has throughout required the greatest attention.

Since the foregoing paper was read, I have seen two similar cases.

I subjoin brief histories of them, as one well illustrates the earlier stages of the disease, the other its slow progress.

CASE V. On October 14th, 1862, I was consulted by Miss —, a very stout lady, but with small bones, for an injury of the left foot, occasioned on the previous night by stepping on the outside of the foot from a railway carriage to a station platform, the floor of the platform being much lower than she imagined.

The whole foot was swollen and painful; but the principal pain was caused by pressure upon the heel, or by firmly grasping the astragalus and slightly moving the calcis, or by thrusting the finger against the front of the interosseous ligament. She remaining only three days in bed; the treatment, she being of a very gouty habit and requiring a good deal of fresh air, was a compromise; I obtaining for the foot as much rest as I could. In exact proportion to the rest was the improvement in the joint.

The case went slowly but favourably on till after extra exertion, when the peculiar swelling I have attempted to describe made its appearance, but was subdued by rest for a day or two and leeches, leaving behind it only the general swelling of the outer tissues caused by the strain.

On December 24th, she left this for London, unable to bear the weight of the body on the foot; that is suffering from pain when the joint was used. Her treatment now, under advice, is to be "hot douches and shampooing."

This case was under my care from Oct. 14 to Dec. 24, with but slight improvement; in fact, it is a condition which must have time for its recovery, as witness the next case.

CASE VI. Joseph Needorm, aged 55, was kindly brought under my notice by my friend, Mr. Henry Grace of Kingswood. Twenty-nine weeks since, the patient stumbled over a man laying on the floor, and struck the ground sharply with the outer edge of his right foot; he strained his foot, was in bed a month, felt so much better after this time that he attempted to walk; but on his return home found his foot as bad as it had been at all. For these last twenty-five weeks he has not been fully resting the foot, getting up every day, and using external application, but without any benefit.

Dec. 27th. I saw him for the first time. He had pain on pressing the heel bone upwards, pain on grasping the astragalus and moving the calcis on it, pain on pressing the anterior part of the interosseous ligament, and the peculiar swelling underneath each malleolus; he was unable to bear the weight of his body on the foot, and was obliged to walk with crutches. I recommended rest and patience.

These cases are of importance as confirming the conclusions arrived at in the paper; and, further, as showing how frequently the astragalo-calcaneal joint is affected in apparently slight injuries of the foot.

## British Medical Journal.

SATURDAY, JANUARY 17TH, 1863.

### THE THROES OF HOMŒOPATHY.

WE have received, with our other literary new year's gifts, a pamphlet from a practiser of the art of homœopathy. There are things in it worthy of notice, because they exemplify in a very striking manner the benefits which have been bestowed upon the medical profession by the British Medical Association and its JOURNAL in the matter of consultations of medical men with homœopaths.

In this pamphlet is let loose upon the Association and its JOURNAL the excessive wrath of homœopathic fulmination, because, as is asserted, through its influence has the determined stand against these homœopathic consultations been made and effected. The pamphlet is entitled *Remarks upon Archbishop Whately's Letter on Medical Trades' Unions*, and is from the pen of a gentleman who writes himself "M.D. (Hon.)". On referring to the *Directory* for the explanation of this ambiguous title, "M.D. (Hon.)", we find that our author was dubbed "M.D." by his Grace the Archbishop of Canterbury in 1850. No wonder, therefore, that having passed an examination necessarily so homœopathic in its scientific and medical qualities, he should feel himself bound to defend the vagaries of homœopathic practisers and of all eccentric archbishops.

We need not again refer to the archiepiscopal epistle of logical Whately, which this gentleman defends, having only a week or two back said our few words about it. What we wish is, that the Association should have the satisfaction of knowing what grave charges the homœopath lays to its door.

"The persecuting policy of the *British Medical Association* goes further than this. It not only deters the heads of the profession from the investigation of homœopathy, by threatening to deprive them of their well-earned honours, if their investigation should end in the acknowledgment that *homœopathy is medical truth*; but it forbids the heads of the profession to consult with members of the homœopathic school, or to extend to them their professional aid. The British Medical Association is not content, like the *Irish College*, with ordaining that its members shall not consult with homœopaths; but by recent enactments it forbids its members to consult with those heads of the profession who give homœopathic physicians and surgeons their aid."

The homœopathic pamphleteer then goes on to show how the Association "has intimidated the boldest surgeons"; and laments over the fatal conclusion that surgeons of the highest grade one after the other have found themselves forced to "succumb" to this professional, or, as he calls it, "unprofessional" opinion. He relates how they were "compelled either to give way or to suffer continued

annoyance, vexation, and pecuniary loss"; and he relates how they have given way, rather than subject themselves to such loss and annoyance. Could any greater praise be given to our Association? Could any greater homage be paid to the power and integrity of this Association? The homœopath knows well enough, and by his silence recognises the fact, that, so far as the *Lancet* was concerned, he might to this day have enjoyed his consultations with the "boldest" surgeons in the profession. He has, therefore, not one word to say against that journal for the part it played in the memorable struggle. The disgrace or the credit of arresting the commercial union of surgeon and homœopath lies solely to the account of the will of the British Medical Association, as expressed through its JOURNAL.

We think we may venture to rest for a moment with complacency upon this immense service done to the profession by the Association—this strangling, at a most critical period of its growth, of the produce of the hybrid conjunction which was then coming into vigorous life.

One word to the homœopaths. We would gladly, if it were possible, make them understand how little there really is of any "medical terrorism" or of "trades-unionism" in our method of dealing with the golden image which they have set up for their own especial worship. We never interfere with homœopaths or homœopathy. We never interfere between the victim and the victimiser, as we regard his patient and him. We never attempt to persuade an admirer of homœopathy not to consult a homœopath. We leave homœopaths, adviser and advised, to their own unlimited inclinations. The reason is obvious. Every man of experience knows well enough that to argue with any one on a point of credulity is simply to confirm him in his credulity. When a man believes in homœopathy, he believes in that which is beyond the reach of reason. He believes first, and finds his reasons afterwards. And the natural consequence is, that in all matters of credulity, the more absurd—*i. e.*, contrary to reason—the thing believed in is, the more firmly does it take hold on the credulous mind. To argue, therefore, with the credulous is, as we have said, first of all utter waste of time, and secondly only makes the credulous more deeply dyed in his incredulity. But what we do is simply this: we affirm that no medical man can honestly consort with homœopaths, because, homœopathy being acknowledged by all medical men to be a delusion and a gross evil, he who does so consort with homœopaths indirectly and *knowingly*, by his presence and countenance assists in the propagation of the delusion and the evil. We, therefore (and, as it seems to us, according to the plainest rules of medical morality), are forced to affirm that such consultations are acts of high professional immorality, and demand the

stringent censure of professional opinion. We affirm that no professional man has a right to play fast and loose with the art of medicine. Let him choose to stand by his calling, by his Hippocratic art; or let him choose to fall away with those who practise a mockery of it. But far off may the day be when the profession will sanction the indirect patronage of homœopathy, or of any other quackery, by any of its members; when the profession will stand unmoved while men, of high position it may be, for the love of gain, meet in consultation those whom they know and admit are victims of and practisers of a dangerous delusion. To call upon the profession at large to withdraw their confidence from such men is plainly the inevitable duty of the Association; and to call upon the men themselves to abstain from such practice is plainly to recall to their minds the duty which they owe to themselves and to their profession.

#### THE REGISTRATION OF BIRTHS, DEATHS, AND MARRIAGES IN IRELAND.

THE following remarks on this subject have appeared in the *Dublin Medical Press*. The subject, as many of our readers are aware, is one which is at present exciting particular attention, and which, for many obvious reasons, demands an early and definite settlement:—

"It must be evident to all, from the fact that within the last three years three measures for the registration of births and deaths in Ireland have been presented to the House of Commons for their acceptance, and also from the strong expressions of opinion which have been recorded through the *Press*, and more recently at the meeting of the Irish Medical Association at the Limerick Junction, that a general system of registration is peremptorily demanded by the public. It is plainly the opinion of most persons that none of the three measures which have been already before Parliament would be likely to afford a satisfactory mechanism for the carrying out of such registration, and we have therefore endeavoured, profiting by the arguments adduced by speakers at the late meeting of the Association, and after a careful analysis of the Registration Bills of Lord Naas, Mr. Cardwell, and Sir Robert Peel, to frame a measure which may effectually carry out the desired objects without imposing unremunerated labours or vexatious duties on the medical profession. The first point, one in which the three Bills coincide, and to which we take the strongest exception, is the injudicious course proposed to be adopted of combining the registration of births and deaths and that of marriages in one central office and under one administration. Now one of the most important features of the measure is the registration of causes of death. Is the whole machinery of the Bill to be rendered nugatory by compelling the results to pass through the hands of a non-professional man? We propose, instead of raising the present Registrar-General of Marriages' salary to £1000 a year, to appoint a Medical Registrar-General of Births, Deaths, and Causes of Deaths, whose knowledge and experience may enable him to turn the valuable statistics which will pass through his hands to the public good. We propose, secondly, to dispense entirely with the services of the Superintendent-Registrars. Thirdly, we propose

to remunerate the medical profession at large for the disagreeable duties which this measure must entail on them, by awarding every medical man who may be called on to register a birth or death the fee of one shilling. We need not say that we consider such a fee as entirely inadequate; but bearing in mind the number of deaths, the depressed state of the country, and the fact that such fee must be paid out of the union funds, it would only defeat our object to demand a larger one. Under the provisions of the draft Bill, the fees paid to the medical practitioners of the district would correspond in amount to those paid to the registrar, and one would check the other; the profession would be remunerated for their labours, and the registry would be efficiently carried out."

### THE EXAMINATION IN SURGERY AT THE LONDON COLLEGE OF PHYSICIANS.

THE announcement that the London College of Physicians has appointed an Examiner in Surgery may fall strangely on the ears of those who were not prepared for the fact; but the fact is, in reality, only a necessary accompaniment of the part which the College has played of late years in medical affairs. The College has, and most properly, assumed its ancient position as the leading examining body of the medical practitioners of this country. It has proved itself equal to the occasion. Emerging from the condition of demi-clubbism into which it had previously lapsed, it has opened its doors to the whole profession, and invited them to enter. One of its most particular privileges, which it had allowed to become obsolete, was the power of examining in surgery. This privilege and right it now once again assumes. It examines in surgery; and we may fairly infer that all the privileges at present accorded by various governing bodies, and in the army and navy, etc., to members of Colleges of Surgeons, will be equally granted to those who have passed the examination in surgery of the College of Physicians.

We would, however, suggest that the College, in this matter of electing an Examiner, has not gone far enough. The importance of the proceeding is such, that the position requires the presence of at least two Examiners in surgery, for the more dignified and solemn carrying out of such examination. We have no doubt that the College will eventually recognise this, and supply the deficiency in their present arrangement.

It may be asked, What will be the effect produced generally, in the practice of the profession, by this novel proceeding? Will it have any influence over the future relations between what are at present called the different classes of the profession? Will it tend more to their unity, or to their further separation? We believe it will have a very important influence, much greater than might be supposed from a mere superficial view of the matter. It seems to us that it cannot fail in promoting the

tendency to one general scheme of professional examination, which is visible at the present time; and, above all, that it will have a powerful influence in removing the unnatural barriers which at present exist in high places between the practice of medicine and the practice of surgery.

It must be remembered that all professional men licensed by the College of Physicians to practise are, *de facto*, physicians; and, therefore, the College issues its licenses to those who, it admits by the fact of its examination, are capable of practising surgery. The London College of Physicians, then, distinctly admits that its Licentiates (who pass the surgical examination) are fit and proper persons to practise surgery; and hence we may fairly conclude that the College does not see anything morally or ethically out of order in the fact of a physician performing surgical manœuvres. We must say we are glad to find things regarded by so high an authority from this point of view. Surely the time has gone by when a President of the College of Physicians could rather allow a friend to depart quietly from life than attempt to save him by condescending to the indignity of performing venesection.

The position which hitherto physicians have taken up, in this matter of surgical interference with disease, has always struck us as a very great absurdity. We have never yet been able to fathom the reason of the thing; nor could we ever understand wherein lay the ethical crime of the man who, having studied surgery as a student, ventures, for example, to pass a catheter as a physician. We all know how our colleagues the surgeons respond to this extreme delicacy and niceness on the part of the physician. Surgeons refuse the treatment of nothing in the way of diseases; all is fish which falls into their hands. Half (we dare say two-thirds would be nearer the mark) the practice of what are called pure surgeons is purely medical practice. The pure surgeon, who has passed no medical examination whatever, does not hesitate to undertake the cure of any disease that falls on mortal flesh; whilst, on the other hand, the physician, who has usually passed through the very same routine of education as the surgeon, and in addition gone through a severe medical examination, is deemed by fashion incapable of performing the most trivial surgical operation! Really, it is time that this absurdity was fully exposed and practically put an end to; and especially so when we come to consider the immense importance which now attaches to the *medical* treatment of surgical diseases. Conservative surgery means nothing but this—it is the medical treatment of surgical diseases. Every day operations and mutilations are becoming less frequent in constitutional affections; and solely because it has been discovered that medical treatment can cure where surgery once mutilated. All this is the great boast of modern surgery, as Mr.

Paget so eloquently explained in his Address in Surgery delivered before the British Medical Association. We believe that there is no class of surgical diseases to which these remarks are not applicable. We would ask the oculist, for example, whether a large percentage of his patients are not of those whose defect of vision depends, not upon any local, but solely upon constitutional causes; and, therefore, solely require medical treatment. We would ask the same question of the aurist, in his department. In uterine diseases, again, the constitutional, the medical treatment—with all respect to the speculum-worshipper be it said—is of as great if not greater importance than the local. In that large class of strumous affections, again, which fall under the surgeon's hands, is not the constitutional the all-important treatment? Has not constitutional treatment saved, for example, many a joint which the surgeon had condemned to the knife?

If, then, as is a fact, medical treatment plays so large a part in the cure of surgical diseases, why is the physician to be excluded from giving his services to their cure? And why, again, what degradation is there, or impropriety, in the physician performing those operations in surgery which he knows he has the skill and the power of performing as well as his surgical neighbour? The pure surgeon, having, it may be, no proof to give of his medical knowledge, is considered capable, and by custom permitted, to cure every disease under the sun; and yet the physician, who may be an excellent anatomist, who may be deeply versed and practised in pathology, who may have had great practice in the use of the scalpel, is to be told that there is a sort of custom (as strong as law) which forbids his performing the most trivial operation on the living body. But, still further to show the absurdity of our customs, we find that a pure physician, if he be an accoucheur, may perform the most formidable operation *in parte obstetricâ*; and that he may become and practise as a first-rate surgeon, if only he keep to the uterus and its appendages!

Let us hope that this new proceeding of the London College may tend to remove the absurd anomaly which now distinguishes our professional relations; and the fact is, that physicians have, indeed, already begun to do surgery in a small way, and we know what may result from such beginnings. Physicians of the most orthodox position may, for instance, "mop out" a throat with nitrate of silver. Physicians may employ the laryngoscope; and we suppose, when they have got the knack of using it, will (without permission from the College of Surgeons) not hesitate to remove growths or "tumours" from the vocal chords, should an opportunity offer for their so doing. We believe, again, that there are *pure* physicians who do not hesitate to apply

caustic to a chancre, for example; and we have even known physicians to pass a catheter (at a pinch), and to do it as well as the rest of the world. We are certain, moreover, that there are physicians, pure ones, we mean (nominally, at least), who would not hesitate to reduce a dislocated shoulder, if suffering humanity required it at their hands.

All this shows that the College has stepped in at the right moment, and has now tacitly said that it will no longer be a party to this absurd division of the body into medical and surgical departments. It now declares (as we read the matter) that medicine comprises surgery, midwifery, etc.; and that, as the major includes the minor, so the physician may consider himself, when properly qualified, justified in treating all diseases that fall under his hands, according to his conscience and his powers. We sincerely trust that the time has now come when a pure physician, not being an accoucheur, may attend a woman in labour if he choose, or perform any other operation, medical or surgical, which he is equal to, without infringing the ethical or other rules of the profession.

#### THE VINEGAR-EEL AND QUACKS.

An interesting paper on the Vinegar-Eel, from the pen of Mr. Jabez Hogg, appears in the last number of the *Popular Science Review*. After giving the natural history of these curious animals, Mr. Hogg points out the uses to which these animals are put by the rascality of our modern quacks:—

"This minute and curious eel is not unfrequently made the means of practising upon the unwary a gross but very characteristic imposition by the advertising quacks who infest this great metropolis. A victim offering himself to be fleeced is usually received in a well made-up room, lined by book-cases and illuminated diagrams of the organic structures in the human body, healthy and unhealthy. Instead of the old-fashioned stuffed alligators suspended from the ceiling, the Paracelsus of modern times ostentatiously parades the most showy and expensive microscope obtainable, in closest consultation with which he takes care to be found by the patient, just as an ant-lion may be supposed to be studying nature as he reposes at the bottom of his conical trap, the sloping sides of which, made up of the finest sand, prove a very *facilis descensus* to his unsuspecting prey who ventures on the treacherous surface. Proceeding to business, after some preliminary anxious inquiries, the doctor (!) gravely proposes to aid his diagnosis by that crucial test, the microscope. The dismay of the poor victim may be more easily imagined than described, when, on being pressed to see for himself, the state of affairs is revealed to his agitated mind, in a mass of wriggling little worms, disporting themselves in the smallest drop of fluid derived from his natural juices. The doom of Herod—"and he was eaten of worms"—to him needs no more elucidating commentary, and if the conscience smitten patient does not, like the tetrarch, presently give up the ghost, he is in a very apt mood to part with all the cash he may have about him, in order to be kept out of a situation, the horrible nature of which, had it not thus been demonstrated to his senses, he could never have conceived. I have sketched no overdrawn picture, but rather one, I fear, of daily oc-

currence; and the manner all this is effected is exceedingly simple. The smallest particle of *sour paste*, previously placed on a slip of glass, lies imperceptible to the unpractised eye, until a single drop of any fluid secretion from the body supplies the required conditions of moisture; and, accordingly, the little paste-eels are immediately aroused to life and activity, reversing the fable of the frogs and boys, as the lively enjoyment they exhibit is apt to prove a very serious matter to the human being so shamefully victimised."

### THE CHLOROFORM COMMITTEE.

WE beg to call the special attention of the profession to the following document, which has been forwarded to us for publication. We need hardly say that the inquiry into the effects produced by chloroform is one of deep interest to humanity; and we are satisfied that the profession generally will give their best assistance to the Committee who have undertaken to carry out the investigation.

"The Committee of the Royal Medical and Chirurgical Society, appointed to investigate the effects produced by the administration of chloroform, consider that the cooperation of the profession is necessary to enable the Committee to pursue their investigations in a satisfactory manner; and they are, therefore, desirous it should be generally known that their primary object is to inquire into the use of chloroform by inhalation, and its results (a) in the treatment of internal diseases, such as tetanus, delirium tremens, asthma, epilepsy, and infantile convulsions; (b) in surgical operations; (c) in obstetric practice.

"The points on which the Committee at present especially desire and ask for information are the following:

"1. Reports of any unpublished cases of death during the administration of chloroform, or of any other anæsthetic.

"2. More complete reports of fatal cases already published.

"3. Notes of any accidents with chloroform in which death has been threatened but averted.

"4. Facts as to the effects of chloroform employed by inhalation as a remedial agent in disease; the mode of its administration; the quantity used; and the results, both immediate and subsequent.

"5. Notes as to the comparative results of operations before and since the introduction of anæsthetics.

"Gentlemen who may be disposed to oblige the Committee by furnishing information on these subjects are requested to address their communications to Mr. Callender, Reporter to the Committee, Royal Medical and Chirurgical Society, 53, Berners Street, W."

### THE WEEK.

THE January number of the *Journal of Mental Science* contains some interesting and valuable papers. Dr. C. L. Robertson (the editor) contributes one on "The Want of a Middle Class Asylum in Sussex". Dr. H. Maudsley treats of "Hereditary Influence". Dr. Kenneth McLeod, in a paper entitled "Practicable Mental Science", examines two important communications from the pens of Dr. Laycock and Dr. J. S. Bushnan, on "The Principles and Method of a Practical Science of Mind", and on "the Practical Use of Mental Science". Dr. J. Crichton Browne

concludes his remarks on "Personal Identity and its Morbid Modifications". Dr. Arlidge gives a "Quarterly Report on the Progress of Psychological Medicine", containing a vast amount of very interesting information. Under the head of "Medico-legal Cases", the trial of Hall v. Semple is referred to at length by Dr. Harrington Tuke. We are glad to find that the *Journal of Mental Science* takes very much the same view of the case as has been expressed in the *BRITISH MEDICAL JOURNAL*. The following remarks, as to the non-presence of lunacy doctors, are well put, though we cannot say we agree altogether with their purport.

"It is with no spirit of bitterness or sarcasm that we would mark this painful case as one which illustrates the danger the public must incur, if the administration of the Lunacy Law is left solely to medical men, who, however well meaning, are without sufficient experience to decide a doubtful case, and are, through ignorance of technical forms, liable to involve themselves and others in serious legal difficulties. It is but a few months ago that physicians engaged specially in the study of insanity were exclaimed against as theorists, their evidence was to be excluded from courts of justice, it was recommended that their asylums should be handed over to intelligent laymen, and it was gravely asserted that men of common sense and knowledge of the world were equally competent with them to decide as to the existence or non-existence of insanity.

"With certainly no amicable feeling towards 'mad doctors,' an amendment of the Lunacy Act passes through the legislature, and by a sort of poetical justice, the first trial that occurs after this becomes law presents us with the spectacle of an apparently sane man who, upon the informal certificates of two gentlemen who are not 'mad doctors,' is dragged off in the most barbarous manner to an asylum, whose proprietor, again, is not a 'mad doctor,' but who nevertheless keeps the patient, whose sanity he says he recognised, till his discharge by the Commissioners in Lunacy on account of the hopeless invalidity of his certificate. In all these proceedings, from first to last, no 'mad doctor' appears upon the scene, and we are surely justified in expressing an opinion that, if the advice of a physician experienced in cases of insanity and accustomed to weigh evidence, had been sought, a grievous wrong might have been avoided and a great public scandal prevented.

"But this does not seem the view of the public, who, although the lunacy law was in this case broken, and cannot, therefore, be said to have failed—although the Commissioners in Lunacy promptly redressed the wrong that had been committed, for which no 'mad doctor' was responsible—renew their clamour against our profession, and ask angrily for new laws and for vindictive punishments."

We cannot agree with the writer that *special* knowledge is requisite on the part of the examining medical man. No man is forced to give a certificate of lunacy; and we say, let every man abstain from giving such a certificate who has not personal proof of the insanity of the individual the state of whose mind is questioned. We disbelieve in the fine subtleties of psychological pathology, just as we disbelieve in the use of fine-drawn, hair-splitting signs, in stethoscopic diagnosis, as indications of internal diseases. We are inclined to believe that any properly educated medical man can (if not led away by his

feelings or his trust in others) determine whether the words or actions of an individual savour or not of lunacy. At the same time, we willingly admit as, indeed, *primâ facie* evident, that medical men who are constantly dealing with the speciality of lunacy must acquire special and peculiar powers for dealing with its treatment and management. We congratulate the Association of Medical Officers of Asylums and Hospitals on the vigour and life of their journal.

DR. ARTHUR FARRE has resigned the appointment of Professor of Midwifery in King's College, and of Physician-Accoucheur to King's College Hospital. This is another of the many good examples of resignations of public hospital appointments by senior members of the profession which have of late been recorded.

THE *American Medical Times* gives the following summary of medical events during 1862:—

"The civil war, which rages with undiminished violence, has, during the past year, made still further draughts upon the profession. The addition of another assistant surgeon to each regiment drew largely upon the young practitioners of the country, but the corps was promptly filled with, in general, well qualified surgeons. The subsequent immense increase of the army, demanding three surgeons to each regiment, has called from civil life another, and, we believe, a still more competent class of surgeons.

"During the past year our military hospitals have gradually increased in number and extent, until they form a grand and imposing system such as has never before been witnessed. The aggregate of sick is now never below 50,000, and has reached the enormous figure of 90,000.

"The re-organisation of the Medical Department of the army was happily effected in the early part of the year, and the good results have been incalculable. The important precedent is now firmly established, that its chief officer shall be selected on account of merit and qualifications, and not on the score of his age. The vigour and efficiency which General Hammond has infused into every branch of the medical service are sufficient evidence that this was a vital element of the reform sought. The Medical Staff also gained rank, which has given it a more respectable, as well as commanding position.

"It would be pleasant to extend to our 'Southern brethren' the courtesies of the season, and learn the state of the medical sciences in that tabooed region yeapt 'the Southern Confederacy.' But the land and water blockade is so effectual, that we are as ignorant of the medical affairs of C. S. A. as of Japan. Occasionally we see an old familiar name among army news, but it disappears for ever in the impenetrable gloom that overhangs that devoted country. We inquire in vain for its medical periodicals and its medical colleges. A London contemporary has, indeed, noticed the second edition of a work on military surgery, by our former correspondent, Professor Chisholm, of Charleston, S.C., issued at Richmond. This is the only contribution to medical literature in the Southern States, of which we have any knowledge.

"Since the commencement of the rebellion, with the exception of the American Medical Association, the medical societies, State and local, have exhibited commendable activity. They have all had their stated meetings, and the discussions have, in general, been unusually interesting.

"Medical publishing has suffered even greater depression than during the preceding year. Periodical literature has been but poorly sustained, and the pressure which scarcity in paper now produces threatens complete suspension. But few books have been issued, and those, almost without exception, have been small works on military surgery.

"The Medical Schools are very well sustained, and in some instances largely increased classes have been the result of the demands which the army and navy are now constantly making upon the profession."

Oppolzer's numerous students have determined to establish a marble bust of their favourite teacher.

## THE SALPETRIERE AND BICETRE.

DR. LEE of Philadelphia, who has lately visited these establishments, writes as follows on them:—

"The great Hospice *Salpêtrière* is both an almshouse and a hospital, chiefly for incurable, epileptic, or lunatic female patients, and patients advanced in age. It contains 5,204 beds, of which 2,917 only are occupied by real patients. It is an immense establishment, consisting of forty-five distinct buildings, extending 1,680 feet in length. The hospital receives, first, the *reposantes*, women who have been in its service thirty years, and who are upwards of sixty; second, indigent old women, upwards of ninety, afflicted with incurable maladies; third, insane and epileptic females. The lunatics, of whom three-fourths are considered dangerous, are kept in separate infirmaries and treated with the greatest care. I saw several hundred of them sitting at the supper-table, each with an ample allowance of wine, and a plate of ripe plums and apricots, besides bread, etc. It was a delightful sight to see the cheerfulness of the old ladies, and hear their merry chat as they partook of their evening meal.

"The *Bicêtre* is situated on lofty ground, differing in this respect from the *Salpêtrière*, and enjoys a more salubrious air than most of the Parisian hospitals. It is an asylum for indigent old men and male lunatics, and receives about two thousand patients. It presents a square of nine hundred feet on each side, and contains three courts. The indigent and infirm old men occupy the greater part of the building. They have no private rooms, but there are large rooms with workshops and dormitories, as also several gardens and court-yards for exercise. They are obliged to work three hours a day at their respective trades, or other occupations, and receive in return a share of the profits; the rest goes towards defraying the expenses of the establishment. The daily allowance to the indigent is a portion of soup, a pound and a quarter of bread, four ounces of meat for dinner, vegetables or cheese at night, and a quarter of a pint of wine. The average daily cost of each is nine sous (cents), and the total annual expense about nine hundred thousand francs. The number of lunatics, idiots, and epileptics is about nine hundred, who have the same allowance as paupers, except a larger allowance of bread. Physical restraint, by strait jackets, etc., is very common. Generally, however, the treatment is very mild, and daily employment is given on a model farm and bleaching-ground, where there are also sties for breeding swine of superior breeds. This farm not only supplies the establishment, but produces sufficient to partly supply the other Parisian hospitals. There are various kinds of schools in the establishment for lunatics of all ages. Instrumental concerts are often given by the patients. Voisin, Delasiauve, and Moreau, are the physicians having charge of the lunatics."

## Progress of Medical Science.

**CONGENITAL CERVICAL FISTULA.** F. Mayr found in a little girl, aged 6 years, a double congenital cervical fistula. On each side of the trachea, symmetrically placed at the inner border of the sterno-mastoid, at a distance of two *centimètres* from the origin of this muscle, was a small depression of the size of a hemp-seed, in the midst of a circular projection; from this point a cord could, especially on the left side, be felt under the skin, proceeding towards the hyoid bone. At the upper limit of the depression, the skin formed a falciform projection, beneath which a pig's bristle or a fine sound could be introduced through a scarcely perceptible opening into a tolerably roomy canal, and passed along in the direction of the subcutaneous cord,  $2\frac{1}{2}$  German inches on the right side, but only  $1\frac{1}{2}$  inch on the left. The introduction of the sound on the right side to the distance of about an inch produced violent coughing, which increased when the instrument was passed further on, and ceased when it was withdrawn. The communication of the canal on the right side with the trachea was proved by injecting fluid, which, without producing cough, was either swallowed or spat up. The end of the sound could neither be seen nor felt in the mouth; and it was not possible to use a laryngoscope. The matter discharged from the canals at first consisted of two or four drops daily of a serous fluid; but afterwards it became more copious, thick, and purulent. The presence of a diverticulum of the œsophagus above the bifurcation of the trachea was also rendered probable by the fact that the child, who was greatly emaciated, was often unable to swallow anything, and for days together would reject all food, during which time not even the finest bougie could be introduced into the stomach; but, at last, this condition would spontaneously disappear. Mayr believes that the œsophagus became compressed by the filling of the diverticulum with masses of food; and that the dysphagia disappeared spontaneously when the food, softened by maceration, was discharged into the œsophagus by the movements of the parts. (*Jahrb. für Kinderheilkunde*; and *Archiv für Klin. Chir.*, Band 3, Heft 3, 1862.)

**PERIPLEURITIS.** Under this name, C. A. Wunderlich describes an affection in which the subserous tissue of the costal pleura and the adjoining soft parts become the seat of inflammation and suppuration, while the serous membrane and its cavity is only secondarily affected. In such cases, a remarkable train of symptoms are manifested, which cannot be well understood without a knowledge of the anatomical origin of the disease. Wunderlich relates two cases in support of his theory. A healthy man, aged 27, had a severe attack of some affection of the chest (probably pleuropneumonia), which passed away spontaneously; three months later he had peripleuritis. The abscess communicated with the lung; there was cutaneous emphysema on the left side; the pleural cavity contained no air, but there was fluid at its lower part; there was also Bright's disease. In the other case, a man aged 55, who had bronchial dilatation, was attacked with peripleuritis on the left side; a hard swelling also formed in the walls of the chest. At first there was fever with prostration, and at a later period a pseudo-typhoid state without fever; bronchitic *râles* were heard; and there was slight albuminuria. He died at the beginning of the fourth week. There was a large peripleuritic abscess, with secondary destruction of the costal periosteum and erosion of the ribs; numerous abscesses were found under the left costal pleura, one under the right. The serous lining of the pleural cavity was much injected, and the cavity

contained an exudation which agglutinated its walls. There was bronchial dilatation on both sides. The portion of lung lying beneath the peripheric abscess was healthy. There were small purulent deposits beneath the endocardium, and scattered abscesses in the liver. The spleen was large and soft. Both kidneys contained numerous purulent deposits both on the external parts and internally. (*Archiv für Heilkunde*; and *Archiv für Klin. Chir.*, Band 3, Heft 3, 1862.)

**CONGENITAL BIFID BLADDER: CALCULUS.** M. Angelo Scarenzio relates the case of a cretin lad, aged 19, who had a largely developed penis, with hypospadias in the first stage, and division of the prepuce into two lateral lobes. The patient had been six times submitted to lithotripsy; but, as he still suffered very much from the pieces of stone remaining in the bladder, lithotomy was performed at the end of six months, and three large and two small calculi of phosphate of lime were removed. No other fragments could be discovered by the finger. Three weeks afterwards, a new calculus was discovered; but the patient would not allow it to be removed either through the opening in the perinæum, which was still fistulous, or by lithotripsy. Two months after the operation, he died of peritonitis. On *post mortem* examination, a large quantity of sero-purulent fluid was found in the peritoneal cavity. The bladder was divided into two halves by a deep furrow on the middle line from before backwards; the middle coat was hard and hypertrophied. In the interior were two well-marked cavities, each seven or eight *centimètres* in diameter, communicating by an opening of about three and a half *centimètres*. At the mouth of the right cavity was an oval fragment of calculus, about thirty *millimètres* in diameter. The mucous membrane was livid, and ulcerated in parts; and between it and the muscular coat were several small abscesses. Below the divided part of the bladder, next to the urethra, was a third cavity, oval in form, including the neck of the bladder, and having a long diameter of four or five and a transverse diameter of three *centimètres*. (*Annali Universali di Medicina*; and *Archiv für Klin. Chir.*, Band 3, Heft 3, 1862.)

**STATISTICS OF LITHOTOMY.** Dr. Zett has contributed to the statistics of lithotomy the results of his practice, extending over a period of fifty-two years. He has performed the lateral operation 108 times; viz., in 103 men and 1 woman, with a fatal result in three cases only. The operation was performed three times on one man, and twice on each of two others. Seventy-three of the patients were from one to twelve years of age, and of these twenty-two were from two to four years old. Of men between thirty and seventy years old, only ten were operated on. The number of calculi extracted was 199 in 107 operations. In one case, 73 were removed; viz., 23 by extraction through urethra; 43 by incision of the urethra; one large calculus by lithotomy, and five two days later; and in another instance ten were removed. The success of M. Zett is attributed to the following circumstances; the general good health of the people; the youth of most of the patients; the absence of excessive hæmorrhage and urinary infiltration; and his practice of drawing the skin to the right so as to form a covering to the wound. He also kept his patients without drink for some days before and after the operation. (*Wurtemb. Zeitschr. für Wundärzte*; and *Archiv für Klin. Chir.*, Band 3, Heft 3, 1862.)

**FRACTURE OF THE SPINE: RECOVERY WITHOUT PARALYSIS.** Dr. J. Stein, in an inaugural dissertation, relates the case of a plasterer who had fallen six times from scaffolds or high beams. On the third occasion, which took place nine years before his death, he fell on his rump from a beam in the third story of a house. He was unable to rise, and showed signs of paralysis of the

lower limbs and of the pelvic organs; at the middle of the back there was an angular projection backwards of the spine, indicating fracture. He, however, improved; and in nineteen weeks was able to walk on crutches, and partially resumed his work in six months. After some years, he was perfectly able to work; but he remained bent, and felt pain in the seat of fracture during changes of the weather. He subsequently had two severe falls, in one of which he dislocated his thigh. At last he fell from a beam thirty feet high, which produced fracture of the ribs and pelvis, and laceration of several internal organs. Death took place in an hour and a half. The *post mortem* examination was made by Kussmaul. At the part corresponding with the seat of fracture, the body alone of the twelfth dorsal vertebra was found to have been broken; its anterior part was narrowed, so that there was an interval of two lines only between the last dorsal and the first lumbar vertebra. The part of the vertebral canal corresponding to the twelfth dorsal vertebra was somewhat narrowed, principally at the upper part, where its diameter was four lines, while at the middle of the eleventh dorsal vertebra the diameter was seven lines. The cord and its coverings appeared quite healthy. (*Archiv für Klin. Chir.*, Band 3, Heft 3, 1862.)

**ACTION OF ELECTRICITY IN THE METAMORPHOSIS OF ORGANIC SUBSTANCES.** Herr Van Deen has for some time carried on a series of researches with the view of ascertaining whether the chemical changes which take place in the animal body can be produced artificially by subjecting the materials to be changed to the influence of an electrical current. He has therefore submitted to a continuous current various substances which form part of the body or are used as food; viz., serum of blood, milk, urine, albumen of eggs, biliary and urinary acids, glycin, starch, dextrin, sugar, glycerin, etc. He here relates especially the result of his experiments on uric acid. A little uric acid (which is ascertained to be free from urea) is mixed up in a large quantity of water, so that a part is dissolved. The apparatus employed consists of two elements of Bunsen's pile, with platinum electrodes, which are immersed (being separated by a piece of glass) in the vessel containing the substance. In ten or fifteen minutes, even though the current has been weak, urea can be detected. If warm water be added, the action becomes more rapid and intense. The quantity of urea formed is in direct relation to the time during which the current has acted on the uric acid. If the current were continued for a sufficient length of time, he found distinct crystals of urea, the nature of which he confirmed by forming nitrate of urea. He believes that carbonic and oxalic acids are formed with the urea, but is not positive on this point, although he sometimes found crystals resembling those of oxalate of urea. (*Archiv. für die Holland. Beiträge zur Natur-und Heilk.*, Band 3, Heft 2, 1862.)

In the same number is contained a summary of the results of Van Deen's experiments. He has obtained by means of the continuous current—1, from *albumen*; cells resembling cytoïd corpuscles; a substance insoluble in water (fibrine?); urea; allantoin; and uric acid (very probably); 2, from *mucus*; morphological elements; uric acid; and urea; 3, from *uric acid*; urea and allantoin; 4, from *glycin*; urea; 5, from *thein*, urea; 6, from *glycerine*; sugar and lactic acid; 7, from *inosite*; lactic acid; 8, from the *lactate, formate, acetate, and butyrate of lime*; carbonate of lime and water; 9, from *tartrate of lime*; carbonate and oxalate of lime; 10, from *gum*; carbonate and oxalate of lime, and water; 11, from *mannite*; sugar; 12, from *amygdalin*; sugar; hydrocyanic acid; and probably volatile oil of almonds; 13, from *tannic acid*; sugar and gallic acid; 14, from *sallein*; sugar and saligenin or saliretin. Electricity has no influence on starch, dextrin, glycogen, or sugar.

He has also subjected various substances to the action of ozone, with the following results: 1, from *uric acid*; urea and allantoin; 2, from *glycin*; urea; 3, from *glycerine*; sugar, and very probably lactic acid. Ozone appears to have influence on starch. Nitric acid and heat produce sugar from starch, the *corpora amylacea*, mannite, and gum. The fresh pancreas of a dog, whether the reaction was or was not acid, produced fatty acids, glycerine, and sugar from butter; and sugar from glycerine. At a temperature of 104° Fahr., calves' liver produced glycogen and sugar from glycerine, sugar from starch, and, at the ordinary temperature, sugar from dextrin.

**ACETATE OF LEAD IN PNEUMONIA.** M. E. Leudet of Rouen gives the results of his experience in the treatment of pneumonia by acetate of lead. He has given this remedy in forty cases, of which thirty-seven recovered and three died. The mean age of the patients was 36½ years. Of those who died, one was 56 and the other 57 years old; the third, whose age was 37, had been previously treated by tartar emetic in large doses, and presented symptoms of inflammation of the mouth and pharynx. The mortality has thus been 7 per cent. Five of the patients were from 16 to 20 years old; twelve from 21 to 30; six from 31 to 40; six from 41 to 50; eight from 51 to 60; and two above 60. Of the whole number, thirty-one were males and nine females—a favourable circumstance, according to the statistics of Huss and others. The pneumonia was double in one case only. Of the thirty-nine unilateral cases, the base was affected in twenty-three cases, the apex in ten, the middle of the lung in one, and the entire lung in five cases. The amount of acetate of lead given in twenty-four hours varied from a grain and a half to twelve grains. The total quantity administered in the course of the disease varied in different subjects from seven grains and a half to eighty grains; the average quantity was nearly two scruples. The duration of the use of the medicine varied from one to fifteen days, the average being six days. The medicine was always given in the form of pill. M. Leudet has not observed in his patients any signs of lead-poisoning, nor the "lead-line" on the gums, nor constipation. On the contrary, diarrhoea was observed in more than half of his cases, most of whom were taking large doses of the acetate of lead. He gives reasons for believing the diarrhoea to have been a result of the treatment, and not of epidemic influence, or other causes. When the treatment was commenced in the first four days of the disease, a cure was obtained, in thirteen cases out of thirty-seven, before the twelfth day; and when the medicine was first given between the fourth and the eighth days, the average date of cure was the fifteenth day. The effect on the pulse was to diminish the number of pulsations from 100 and upwards (to 120) down to 70, 60, and even 50 or 40, on the fourth day after commencing treatment. In most cases, M. Leudet has not found the pain in the side relieved by the acetate of lead, but has been obliged to employ local bloodletting. In twenty-seven cases, the period at which the sputa lost their rusty colour was observed. In twenty cases, the decoloration was complete from the sixth to the ninth day. In one-half of the cases, the returning crepitant rhonchus was heard after the first day of treatment. In nine cases out of thirty, the stethoscopic signs remained stationary for two or three days, when resolution manifested itself. In six cases out of thirty, the symptoms increased in intensity after the treatment was commenced; but this state continued one day only in five cases, and two days in another. Where once resolution has commenced, it is useless to continue the acetate of lead. In two cases, M. Leudet observed relapses, one of which occurred while the lead was still being given. Convalescence was very rapid; and the appetite returned as soon as the fever disappeared, even

before the resolution of the disease was well established. (*Bulletin Génér. de Thérap.*, 15 Nov. 1862.)

## Association Intelligence.

### BRANCH MEETINGS TO BE HELD.

NAME OF BRANCH.	PLACE OF MEETING.	DATE.
NORTH WALES. [Ordinary.]	Dudley Arms Hotel, Rhyl.	Tuesday, Jan. 27, 1.22 P.M.

### NOTICE REGARDING NEW MEMBERS.

By desire of the Committee of Council, the General Secretary requests that the Local Secretaries will be good enough to forward to him the names of all New Members who join the Association through the Branches; as otherwise the JOURNAL cannot be sent to them.

PHILIP H. WILLIAMS, M.D., *General Secretary.*

Worcester, November 10th, 1862.

### NORTH WALES BRANCH.

An ordinary meeting of the members of this Branch will be held on Tuesday, January 27, 1863, at 1.22 P.M., at the Dudley Arms Hotel, Rhyl.

Gentlemen having papers or cases to communicate, will please to give an early intimation of the same to the Secretary.

D. K. JONES, *Hon. Sec.*

Beaumaris, January 13th, 1863.

## Correspondence.

### PUBLIC VACCINATION.

LETTER FROM A. B. STEELE, Esq.

SIR,—The suggestions for an amended Vaccination Act, contained in Mr. Fletcher's letter in the JOURNAL for January 3, appear to me to be based upon a misconception of the real difficulties of the case; and, as the subject is of considerable importance, perhaps you will afford me space for a few remarks.

For the purposes of vaccination, the public may be divided into two classes. The first comprising those whose social position enables them to secure the services of a "family doctor," and who for the most part duly appreciate the benefits of vaccination, and may safely be left to take care of themselves. The second class consists of those who are unable to provide medical attendance at their own cost, and therefore, are necessarily the objects of gratuitous vaccination; and, it is to this class that the operation of the Vaccination Act is almost exclusively limited.

The long and extensive experience of the National Vaccine Establishment has conclusively shown, that the most certain and successful plan for keeping up efficient vaccination in a district, is a concentration of the work, so as to secure the establishment of one or more public stations, at which regular periodical vaccination from arm to arm can be continuously maintained, and from whence a constant supply of reliable vaccine lymph can at all times be procured. When these conditions are complied with, it is found that the great mass of the poor will bring their children to the station where they know they can be properly vaccinated. The medical practitioners in the locality can obtain a supply of lymph whenever they require it; and on the whole the system works well. Some, of course, from ignorance, prejudice, and other causes, do not avail themselves of gratuitous vaccination; but my experience as a public vaccinator in

a densely populated district, leads me to believe that the neglect on the part of the poor to bring their children to be vaccinated arises, in the vast majority of instances, from their habits of indolence, procrastination, and want of foresight, which so much prevail amongst them, rather than from any antipathy or prejudice against the proceeding itself. This difficulty would, in my opinion, be most successfully overcome by the appointment of an officer, whose special duty should be to visit from house to house, and to point out to the people the importance of vaccination, using chiefly persuasive means, and only resorting to the powers of the law in extreme cases, which I believe, would but very rarely be met with. The poor would soon discover that the intention of government is not so much to compel them to be "vaccinated, when, where, and by whom the law says they shall," as to place within their reach the full benefits of free efficient vaccination. At two stations with which I am officially connected, not fewer than 1,200 children in a year are brought weekly for vaccination, and this without recourse to the compulsory powers of the Act. Such a system can, of course, only be carried out efficiently in large towns, but the nearer any scheme approaches to this model, the more successfully it is found to work; in thinly populated districts, it is necessary to modify the arrangements in accordance with the suggestion of the inspector as quoted by your correspondent, and I have personally observed the satisfactory results of such a plan in a rural district.

The proposal of Mr. Fletcher, to require under a penalty or imprisonment, that parents should sign certificates of vaccination, is simply impracticable; inasmuch as a large proportion of such people are unable to read and write, and as it is, they often fail to understand, or to make a proper use of the certificate they receive from the Registrar of Births.

The great objection, however, to Mr. Fletcher's scheme is, that it entirely ignores the conditions which have been proved to be essential to the maintenance of efficient public vaccination, namely, regular periodical arm to arm vaccinations by competent operators, and a continuous supply of recent lymph.

In support and confirmation of these views, I would refer your correspondent and others who are interested in the question, to the admirable and comprehensive report of Mr. Simon, in a blue book on Vaccination issued by the General Board of Health in 1857, and also to a paper published in the JOURNAL, March 8, 1862, in which I have drawn attention to the importance of the subject, which is far too comprehensive to be disposed of in a letter.

I must take exception to some of the reasons named by Mr. Fletcher for exemption from penalties, or rather to the terms in which those reasons are stated. For example "(1). Should the child be incapable of taking the vaccine disease"; and again, "(3). Should they (?) be unable to procure satisfactory lymph." The latter contingency ought never to occur in a well arranged system of vaccination, and therefore, should not be officially recognised; and, as to the incapacity for taking the vaccine disease, although I will not venture to assert that such a condition may not exist, yet I believe it to be in the practice of competent vaccinators extremely rare, and the suggestion of such an occurrence on every certificate would be better avoided or provided for in some other way. It is very probable that, in a system of what I should designate irregular and promiscuous vaccination, this particular cause of exemption might frequently be assigned, and this is just one of the many disadvantages which would inevitably accompany such a scheme as that involved in the recommendations of your correspondent, who possibly is not aware of a fact abundantly evident from official records, and to which Mr. Simon, in his report emphatically alludes, namely, that the course of education and the medical and surgical qualifications

of the present generation of practitioners in this country do not necessarily imply a practical acquaintance with the subject of vaccination. Under these circumstances, the government having rendered vaccination compulsory, felt that they were bound to take care that it should be performed in the best possible manner, and under the surest guarantees of competence in the operators, as well as of purity and genuineness in the lymph used in the public service; and it is quite evident that neither of these conditions could be secured if vaccination were left entirely on the hands of the profession generally, without any responsible directing body to watch its progress, and to take such steps from time to time as might be necessary to sustain its efficiency.

I am, etc.,

A. B. STEELE, *Mem. Nat. Vacc. Estab.*

Liverpool, January 5th, 1863.

## AMERICAN AND ENGLISH ASYLUMS.

LETTER FROM JOHN HITCHMAN, M.D.

SIR,—In prominent type, and in a prominent part of the BRITISH MEDICAL JOURNAL, you have placed on record the opinion of Dr. Lee of Philadelphia, on the comparative merits of the English and American asylums. Upon the extravagance of language in which that opinion is couched, I have no desire to comment. It may be, that upon the question, whether the "Americans are the most practical people in the world," and free from "the unreasonable and obstinate prejudice which exists in Great Britain against adopting anything new from foreign countries," neither Dr. Lee nor myself is sufficiently unbiassed to argue fairly. But, perhaps, as the editor of the BRITISH MEDICAL JOURNAL, you may not be unwilling to give equal prominence to the following opinion of another American physician on the comparative merits of the asylums of the two countries. Dr. Butler, the Superintendent-Physician of the Hartford Asylum, Connecticut, thus reports in the Thirtieth Annual Report to the Directors:—

"During the six months vacation which was so kindly granted me by the liberality and indulgence of your Board, I had the pleasure of being able to visit many of the most prominent lunatic hospitals in England and Scotland.

"It is evident, that from a variety of causes, a spirit of improvement is pervading these hospitals. A great impetus has of late years been here given to this department of human effort, and the most beneficial and gratifying results have been attained.

"It is not expedient, in the narrow limits to which I desire to restrict this Report, to go into a consideration of these causes. It is sufficient for my present purpose to say, that notwithstanding a few years since our leading institutions were not surpassed by the best of theirs, *it is very evident to me that we have now none which will compare with some of those lately erected there.*

"In the older hospitals, there was manifest improvement in the buildings, where original defects could never be wholly remedied.

"In the new institutions, those erected within a very few years, or just now going into operation, I found a beauty of structure with a thoroughness and perfection of arrangement which I have never seen equalled elsewhere. Among these it will not, I hope, be invidious to mention the asylums at Prestwich and Cheadle, near Manchester; at Mickleover, near Derby; at Clifton, near York; and the new asylum at Stafford.

"It was evident that in these new asylums no pains or needless expense had been spared to obtain, in the first place, the most unexceptionable plans. The highest authorities were consulted, and their conclusions referred to the scrutiny of other practical men; the errors of preceding structures were avoided, and every im-

provement as readily adopted, with the single desire to obtain the best. It is evident that generally each succeeding structure contains improvements on its predecessors.

"Once adopted, the plans have been carried out without that curtailment and distortion which sometimes, in this country, has produced such unfortunate results.

"In some instances, it is evident that undue expenditure has been incurred to produce external effect; but in the internal arrangements especially, it is clear that while in county asylums everything is plain and simple and unpretending, that is deemed in all the best and wisest economy which, in the long run, shall best effect the desired object.

"The chief points of excellence were extensive, well laid out, and carefully planted airing-courts and pleasure-grounds, and sufficiency of cultivated land for out-of-door employment. Spacious, airy, and well-ventilated apartments, the extensive application of steam to every available purpose, cooking, pumping, heating, ventilating, etc., and open fire-places in every admissible room. The most important of all was the extensive arrangements made for the manual employment of the inmates both within doors and without. There were workshops for the different trades, in some of which these trades had been successfully taught, and in many the amount of work performed showed that the shops were sources of profit to the institution, as well of beneficial employment to the patients.

"Another feature which struck me most pleasantly was the construction in several hospitals of a large and handsome room expressly for the social gatherings and amusements of the patients. My attendance at some of these festival occasions is among the most pleasant reminiscences of my visit. A large amount of profitable out-of-door labour was insisted upon in many, and the amount accomplished in some instances was highly creditable.

"It is very evident that if the American institutions are to maintain the comparatively high rank to which they have justly heretofore had claim, a more liberal expenditure than has been adopted in most in regard to occupation, both of body and mind, amusement, etc., must be adopted."

From the statements of Dr. Lee in your last number, and from the Report of Dr. Butler, it is pleasant to observe that both these nations have been making great progress in a humane direction; and all good men must earnestly desire a cessation of that civil strife which is now absorbing the attention and resources of the American people.

I am, etc.,

JOHN HITCHMAN.

Mickleover, near Derby, January, 1863.

## TRIPLETS AND THE ROYAL BOUNTY.

LETTER FROM JOHN WALSHE, M.D.

SIR,—In the JOURNAL of January 3rd, a paragraph appeared headed "The Royal Triple-Birth Donation", from which it might be inferred that some institution of the kind exists; or, in other words, that any female giving birth to triplets needs only to have that circumstance brought under Her Majesty's notice in order to become the recipient of a bounty for such cases made and provided. This is, indeed, a very wide-spread belief. It is, however, a pure delusion: there is no such Royal Bounty.

On the 4th of May, 1858, I attended Mrs. T., of this city, who on that occasion was confined of triplets. The friends were very anxious that the honour of the Royal gift should be obtained, and application was made accordingly. The result was a communication from Sir Charles Phipps requesting to be informed if the woman, in whose behalf the application had been made, was a person in indigent circumstances, as otherwise the case

could not be submitted to Her Majesty. He also stated that there was no special fund set apart for cases of this kind, and that it was not at all a matter of course that every such case should receive a gift from the Queen.

This "popular error" having been thus demolished, perhaps you will afford me space for a word or two touching the medical aspects of this case of mine—the second, by the way, which has fallen within my own experience, and which may not be uninteresting to some of my brother-members.

The triple birth comprised two boys and a girl. The latter weighed, immediately after birth, 7 lbs. avoirdupois; the boys, 6 lbs. and 5 lbs. respectively. The placenta, which was single, weighed 6 lbs. Thus the entire solid contents of the uterus amounted to 24 lbs. This exceeds anything within the knowledge of my friends here. Even the immense obstetric experience of Mr. Robertson cannot follow it. I should be glad to know if any of our members could report a similar case, as I deem it an important practical point. Mrs. T. had a fair recovery in this confinement, and has since been confined of a single birth. The triplets are still living, and are remarkable in their neighbourhood no less for their great beauty than for their fine healthy development. The girl, however, maintains her congenital superiority in this latter respect.

I am, etc., JOHN WALSH.

42, Oldham Street, Manchester, January 4th, 1863.

## Medical News.

UNIVERSITY OF ST. ANDREW'S. List of gentlemen on whom the degree of Doctor of Medicine was conferred, on December 20th and 24th, 1862:—

Adams, Joseph Dixon, M.R.C.S., L.S.A., Martock, Somerset  
Allanson, Henry George, M.R.C.S., L.S.A., Sheffield  
Angier, George A., M.R.C.S., L.S.A., Ipswich  
Ashforth, George Morris, M.R.C.S., L.S.A., Westmill, Herts  
Aspray, Charles Owen, L.S.A., London  
Aubin, Thomas John, M.R.C.S., St. Clements, Jersey  
Bacon, Mackenzie, M.R.C.S., L.S.A., Norfolk  
Bangsy, Richard, M.R.C.S., Corbridge  
Barrow, Thomas Samuel, London  
Bate, Abraham, L.R.C.S.I., L.M., Donegal, Ireland  
Bennett, James Edward, M.R.C.S., L.S.A., London  
Beuson, Henry, L.R.C.S.I., Dublin  
Beviss, Charles, London  
Biddle, Charles Henry, M.R.C.S., L.S.A., Leeds  
Bloxxam, William, M.R.C.S., L.S.A., London  
Bolton, Andrew, M.R.C.S., L.S.A., Newcastle-on-Tyne  
Booth, Lionel, M.R.C.S., L.S.A., Greenwich  
Booth, Samuel, M.R.C.S., L.S.A., Huddersfield  
Brabazon, William Philip, L.R.C.S.I., L.K. & Q.C.P., Liverpool  
Brecknell, J., M.R.C.S., L.S.A., Durham  
Buckle, William Henry Fleetwood, L.S.A., Royal Mint  
Bucknill, Ebenezer, M.R.C.S., L.S.A., London  
Campbell, Robert L., F.R.C.S.Lond., L.R.C.P.Lond., Inverness

## Examination for Honours.

<i>First Class.</i>	
Bloxam, William, London	} Equal.
Ray, Edward, Dulwich	
<i>Second Class.</i>	
Bright, John M., Forest Hill	Irvine, John W., Lancaster
Prichard, John L., London	Steele, James, Witham
Phillips, Charles H., London	

## APOTHECARIES' HALL. On January 8th, the following Licentiates were admitted:—

Mann, Allen Græme Cheek, Grenada, West Indies  
 Thelwall, William, Farndon, near Chester  
 Trimmer, Henry B., Gloucester  
 Waghorn, Frederick, 34, Soho Square

## APPOINTMENTS.

ALDRIDGE, Russell, M.D., of Yeovil, appointed Certifying Surgeon under the Factory Act.  
 GRAHAM, George, Esq., appointed Senior Assistant Medical Officer to the Surrey County Asylum, Wandsworth.  
 ORANGE, William, Esq., appointed Deputy Superintendent and Surgeon to the Broadmoor Criminal Lunatic Asylum.  
 WYER, Otho F., Esq., of Nunentun, appointed Certifying Surgeon under the Factory Act.  
 POOR-LAW MEDICAL SERVICE.  
 GROVES, Charles, H., M.B., elected Medical Officer to the Ballylough District of the Mallow Union, Ireland.  
 HUGHES, William H., Esq., Resident Medical Officer to the Chorlton Union Workhouse, Manchester.  
 M'BRIDE, Andrew, L.R.C.P.Ed., Medical Officer to the Poyntzpass District of the Newry Union, Ireland.  
 NUGENT, Edmund, L.R.C.P.I., Medical Officer to the Carlingford District of the Dundalk Union, Ireland.

## ARMY.

CAY, Assistant-Surgeon C. V., Coldstream Guards, to be Battalion Surgeon, *vice* J. Wyatt.  
 HENDLEY, Staff-Surgeon J., to be Surgeon 7th Foot, *vice* T. Moorhead, M.D.  
 JAZDOWSKI, Staff-Assistent-Surgeon B. J., M.D., to be Assistant-Surgeon 93rd Foot, *vice* S. Hope.  
 KEARNS, Staff-Assistent-Surgeon W. R., to be Assistant-Surgeon 90th Foot, *vice* S. H. Macartney, M.D.  
 MOORHEAD, Surgeon T., M.D., 7th Foot, to be Staff-Surgeon, *vice* J. Hendley.  
 WYATT, Battalion Surgeon J., Coldstream Guards, to be Surgeon-Major, *vice* J. Monro, M.D.

## To be Staff-Assistant-Surgeons:—

ALSTON, Assistant-Surgeon W. E., M.D., 70th Foot.  
 HOPE, Assistant-Surgeon W. A., M.B., 57th Foot.  
 MCSHANE, Assistant-Surgeon E., 65th Foot.

## ROYAL NAVY.

BAROWING, Benjamin, Esq., Assistant-Surgeon, to the *Cumberland*.  
 BURNETT, Thomas S., Esq., Assistant-Surgeon, to the *Adelaide*, for Plymouth Hospital.  
 GRAHAM, Andrew, Esq., Surgeon, to the *Edinburgh*.  
 MITCHELL, John T., Esq., Assist.-Surg. (additional), to the *Victory*.  
 O'TOOLE, R. B., Esq., Assistant-Surgeon (additional), to the *Forte*.  
 SANDS, John L., Esq., Assistant-Surgeon, to Greenwich Hospital.

## VOLUNTEERS. (A.V.—Artillery Volunteers; R.V.—Rifle Volunteers):—

GILMOUR, A., Esq., to be Surgeon 1st Administrative Battalion Linlithgowshire R.V.  
 PYLE, T. T., Esq., to be Assistant-Surgeon 3rd Durham R.V.  
 To be Honorary Assistant-Surgeon:—  
 BLAIR, D., Esq., 7th Argyleshire R.V.

## DEATHS.

BRISCOE. On January 12th, at the Royal Arsenal, Woolwich, Edith, infant daughter of Henry Briscoe, M.D., Surgeon Royal Artillery.  
 GUNNING, John, Esq., C.B., Inspector-General of Hospitals, at Paris, aged 89, on January 11.  
 JONES, George H., M.D., at Hambleden, Hants, aged 72, on Jan. 3.  
 KINGDON, William, Esq., Surgeon, of Bank Buildings, Lothbury, at Abbey Wood, Kent, aged 74, on January 8.  
 \*MORT, Charles, Esq., at Church Shelton, Shropshire, aged 73, on January 11.  
 NEWINGTON, Charles E. H., M.D., at Ticehurst, aged 50, on Jan. 6.  
 RATCLIFFE, Richard, Esq., Senior Assistant-Surgeon H.M.S. *Melpomene*, at sea, off Bermuda, aged 34, on December 8, 1862.

PLYMOUTH MEDICAL SOCIETY. Dr. J. C. Cookworthy has been elected treasurer and secretary, and Dr. C. R. France librarian, of this society.

NORTH STAFFORDSHIRE MEDICAL SOCIETY. The following officers have been appointed:—*President*, John T. Aldridge, M.B.; *Treasurer*, James Yates, Esq.; *Secretary*, W. H. Davis, Esq.

SUNDERLAND MEDICAL SOCIETY. Dr. H. O. Bowman has been elected president, Mr. G. B. Morgan secretary and treasurer, and Mr. E. A. Maling librarian, of the society.

ROYAL COLLEGE OF SURGEONS. At the recent *preliminary* examinations of candidates, on commencing the study of the medical profession, one hundred and five gentlemen presented themselves, of which number ninety-five were successful.

DENTISTS at RIO JANEIRO. The medical college of Rio has lately made arrangements to instruct and graduate dentists, but in a very imperfect manner. The Philadelphia Dental Cosmos, states that there are about twenty dentists in Rio, most of whom are graduates in medicine, and the Americans, adds Dr. Vegas, are considered the best.

VACANCIES. The following appointments are vacant:—Professor of botany in Anderson's University, Glasgow; medical officer to the west district of the parish of Wednesbury, in the West Bromwich Union; resident medical officer to the Leith Hospital; parochial medical officer for the parish of Abovne, Aberdeenshire; medical officer and public vaccinator for District No. 1 of the Market Harborough Union, Leicestershire.

EXTRAORDINARY SILVER MINE. In the Geological Museum there is a lump of silver—about as much as would make forty shillings—which has been taken from the stomach of a mule in Mexico. It appears to be a common occurrence to find quantities of silver in the stomachs and intestines of the mules working in the Mexican silver mines, and its presence is accounted for by the mules eating mud, which contains much silver, for the purpose of obtaining the salt which is mixed up with it also. The silver is said to accumulate to a considerable extent without proving injurious, and this

furnishes us with another fact to indicate how living tissues tolerate the presence of metallic substances. A correspondent of the *Veterinary Review* facetiously suggests that the Mexican veterinary surgeons will find their fees for *post mortem* examinations in the stomachs of their patients.

**THE HUNTERIAN ORATION.** The biennial oration in honour of the immortal genius of John Hunter will be delivered in the theatre of the Royal College of Surgeons, on Saturday, the 14th proximo, by Professor George Gulliver, F.R.S., a member of the Council of the College.

**INFANTICIDE IN LONDON.** Dr. Lankester has again been calling attention to the frequency of infanticide in London. He says that of seventy-two inquests which he held when he first became coroner, sixteen were on the bodies of murdered infants. Since, then, however, the number had decreased until now he found that there were only twenty-six cases of infanticide in two hundred and fifty-two inquests. This proportion, however, he very rightly spoke of as being discreditable to the metropolis, and he expressed an opinion that much of the prevalence of the crime was owing to the inertness of the police. They had come to regard cases of child murder as things into which it was no use to inquire, and he believed the result would be that familiarity with the crime would soon breed apathy in regard to it so far as the public are concerned.

**DEATH OF JOHN GUNNING, Esq., C.B.** Mr. Gunning, Inspector-General of Army Hospitals, died on Sunday morning, at his house in the Rue du Colisée, Paris, in the ninetieth year of his age. He was, as was observed in the memoir of Sir Benjamin Brodie published in the *JOURNAL* of November 15th, 1862, "probably the only surviving pupil of John Hunter. He was in St. George's Hospital at the time of Hunter's death, and walked at the side of the sedan chair in which Hunter was conveyed to Leicester Square." In 1793, he was elected a Member of the College of Surgeons; and in 1800 was elected surgeon to St. George's Hospital, which office he resigned in 1823. He was attached to the medical staff of the Duke of York's army so far back as 1792, and resumed active service on the outbreak of the Peninsular war—Sir Benjamin (then Mr.) Brodie doing duty for him at St. George's Hospital in his absence. He was also present at the battle of Waterloo, where he amputated Lord Raglan's arm. The *Express*, in noticing his death, says:—"His house was a joyous rendezvous for his own countrymen, at which he delighted to mix with young people and promote their amusement. There was scarcely anything of the old man about him. His sight, hearing, memory—all his faculties, indeed—were perfect to the last; and his friends confidently predicted that he would live to a hundred. On New Year's-day he had a dinner-party; and cards for one of those little friendly dances which he loved to see were issued so lately as last week. An attack of bronchitis prevented him from receiving his friends on the day expected. His medical attendant, Dr. Davison, thought it serious; but it got better, and within the last two or three days was considered to be out of danger. On Sunday morning, however, he expired in his armchair without pain, and with scarcely any previous symptoms to denote an approaching end. His daughter, Mrs. Bagshawe (the wife of the Queen's counsel), and two of his granddaughters, were with him at time of his death."

**THE BLUE GUM TREE.** The *Eucalyptus globulus*, a native of Australia, where it is known under the name of the blue gum tree, was first discovered and described by Labillardière in 1792. This tree only bears blossoms at its very top, so that to get at its flowers the above botanist was obliged to have one cut down. Its dimensions were prodigious, the circumference of the base being 90 feet, and 65 feet at the height of five feet from

the ground; its total altitude was 300 feet English measure, and the section presented upwards of 800 concentric rings. In 1854 Dr. Mueller described it more minutely, and stated that he had met with specimens upwards of 100 metres in height. Although its growth is extremely rapid, being as much as three feet per month in young subjects and during the summer months, its wood is nevertheless extremely hard, so that at Hobart Town and other places it is used as timber for shipbuilding, dykes, piers, etc. Its leaves, moreover, emit a delightful perfume, which is considered extremely conducive to health, especially in marshy districts. In 1860 Dr. Mueller sent over some seeds of this tree to the French Minister of Marine, who immediately dispatched them to M. Hardy, director of the nursery at Algiers. Some of these seeds were also given to the Jardin des Plantes, where a few good subjects are now being reared from them. There is every reason to believe that this remarkable and beautiful tree will be acclimatised in France, or at least in Algeria.

**THE EXTINCTION OF SPECIES.** Mr. Owen, in regard to the extinction of animals assigns the chief weight to "gradual changes which must have accompanied the slow alternations of land and sea brought about in the *æons* of geological time." And he explains, by a reason which is as striking as it is obvious when once pointed out, the phenomenon of only small species of animals existing in countries where much larger species of the same natural families formerly existed; which the ancients, and probably many of the moderns, would be disposed to attribute to a degeneration in the powers of growth. If in consequence of any climatic change the due supply of sustenance for animals in a state of nature falls short, the stress falls upon a species very much in proportion to the bulk of the individuals composing it. Thus, if a dry season is prolonged, a large mammal will suffer from the drought sooner than a small one; and if such prolongation become, by the alteration of climate, habitual, and the quantity of vegetable food be in consequence diminished, it is the bulky herbivora that will first feel the effects of stinted nourishment. A *Bison priscus* or a *Bos primigenius* would starve where a whole herd of Kerry cows might do very well. Hence the diminutive appearance of living species by the side of the enormous fossils extracted from the very soil over which they are feeding is so far from indicating deterioration, that it is, in fact, the characteristic which constitutes their superiority, and has enabled them to accommodate themselves to changes to which their gigantic congeners have succumbed. Extinction, as the operation of a natural law, implies insufficient self-adjusting power to resist the results of climatic variation. Instances of the gradual disappearance of species occur even in the present time. A peculiar amphibious animal which inhabited the mouths of the great Siberian rivers, and fed on seaweed, is supposed to be now extinct, although it existed in the last century. The Great Auk is on the verge of extinction, if not extinct. The bones of this bird exist in numbers on the shores of Iceland, Greenland, and Denmark, but of late it has only been seen on some rocky islets in the vicinity of the first, and of these one—specially named from this bird "*Geirfugla Sker*"—sank to the level of the sea during a volcanic disturbance in the year 1830, and thus diminished the already limited extent of the Auk's breeding ground. The *Dodo* and the *Dinornis*, and the hook-billed parrot of Philip's Island, west of New Zealand, are instances of rare species finally extirpated by the hand of man; and Professor Owen seems to believe the same of the fossil elephant and rhinoceros, which formerly inhabited this part of Europe. The primitive race which effected this result are those who fashioned the flint weapons which have been found in the valley of the Somme near Abbeville, near Hoxne in Suffolk, and at Brixham in Devonshire.

## OPERATION DAYS AT THE HOSPITALS.

MONDAY.....Royal Free, 2 P.M.—Metropolitan Free, 2 P.M.—  
St. Mark's for Fistula and other Diseases of the  
Rectum, 1.15 P.M.—Samaritan, 2.30 P.M.—Lock, Clinical  
Demonstration and Operations, 1 P.M.

TUESDAY....Guy's, 1½ P.M.—Westminster, 2 P.M.

## TO CORRESPONDENTS.

\* \* All letters and communications for the JOURNAL, to be addressed  
to the EDITOR, 37, Great Queen St., Lincoln's Inn Fields, W.C.

CORRESPONDENTS, who wish notice to be taken of their communica-  
tions, should authenticate them with their names—of course not  
necessarily for publication.

ERRATUM.—In the number of the JOURNAL for January 3rd, 1863, at  
p. 11, line 45, in review of Dr. Chambers's work, *Renewal of Life*,  
etc., for "See if quinine will stop ague," read "See if quinine will  
produce ague."

T. S.—The remedy referred to in the note of the wiseacre in the  
*Times* is as old as the hills. We need hardly say that it is as  
capable of warding off and of curing typhus, as the famous curry-  
powder of a noble lord is in curing starvation. That the *Times*  
could admit such nonsense into its pages—nonsense, by the way,  
which, from its admission there, is sure to have effect—only indicates  
the ignorance of educated minds on the subject of medicine.  
The benevolent wiseacre writes:—

"I think it desirable to make generally known a very cheap and  
simple remedy for typhus or other low fever. The remedy is yeast.  
A tablespoonful of this administered in a case where life was all  
but extinct, repeated every ten minutes till the cure was effected,  
restored the patient to such perfect health that he was at his work  
in a few days' time. A small quantity, infused in the common  
drink of those who cannot obtain a sufficiency of nourishing food,  
might infuse such an amount of vitality in the constitution as  
might enable it to resist the depressing tendencies to the dis-  
ease."

THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND:  
TITLE OF M.D.—We have been requested to print the following:

[COPY.]

"King and Queen's College of Physicians in Ireland,

"Dublin, Nov. 10, 1862.

"Sir,—In reply to your letter of the 4th of April, I am directed  
to forward you a copy of the opinion of the Attorney-General for  
Ireland; from which you will see that as a Licentiate of the Col-  
lege, you are legally entitled to assume the title of 'Doctor'; and I  
am further instructed to inform you that if any authority or indi-  
vidual desire to try the question legally, the College is prepared to  
defend the privileges of its Licentiates. The College being in re-  
cess prevented an earlier reply to your letter. You are at liberty  
to make any use you please of this communication.

"I am, sir, your obedient servant,

"LOMBE ATTHILL, M.D., Fellow and Registrar.

"J. Styrap, Esq., M.D., Shrewsbury."

"King and Queen's College of Physicians in Ireland,

"Dublin, Nov. 24, 1860.

"Sir,—I am instructed by the President and Fellows of the  
King and Queen's College of Physicians in Ireland to forward to  
you, for your information, the subjoined copy of the opinion of the  
Right Hon. Her Majesty's Attorney-General for Ireland as to the  
power of the King and Queen's College of Physicians to confer  
the Degree of Doctor of Medicine.

"I have the honour to be, sir, your faithful servant,

"WILLIAM MOORE, M.D., Fellow and Registrar.

"The two Charters of the College, and the several Acts of Par-  
liament bearing thereon, having been submitted to the Attorney-  
General, his opinion was requested on the following query:—

"Whether the Licentiates, as such, of the King and Queen's  
College, are entitled to the Degree and Title of Doctors in Medi-  
cine, and to use the abbreviation or initial letters M.D. after their  
names."

"Answer.—I think the Licentiates and Fellows, as such, of the  
King and Queen's College of Physicians are entitled to the Degree  
and Title of Doctors in Medicine, and to use the letters M.D. after  
their names. (Signed) 'R. DEASY.

"November 21, 1860."

[We understand, and have always understood, that the King and  
Queen's College of Physicians in Ireland rests its claim to the  
power of bestowing the title of M.D. on its Licentiates on some  
special and peculiar clauses in the charter of the College. We  
apprehend that our esteemed correspondent Dr. Styrap will agree  
with us that the charters of the sister Colleges of London and  
Edinburgh contain no such powers. Certainly, the Colleges of  
London and Edinburgh claim no such powers. We have already  
fully explained our reasons for the conclusion which we have ar-  
rived at; viz., that a Licentiate of a College of Physicians who  
demands the courtesy title of Dr. cannot be denied it. Of course,  
we are also equally ready to admit that the King and Queen's Col-  
lege has the peculiar power of granting the degree of M.D., if so  
it be proved and admitted. EDITOR.]

ONE EXAMINATION ONLY.—A correspondent writes:—

"I cannot think the body of the profession have made much  
advance in their position or standing; and the cause, I am in-  
clined to think, is at home amongst ourselves. It is impossible  
that anything like unity can take place when the qualifications  
are so diverse and the examinations so numerous. The man who  
has gone through his legal curriculum, and obtains his double  
qualification, is in no better position than with the single; and he  
with the M.R.C.S. and M.D. Scotch, looks down on the Hall and  
College man, who is the only legal practitioner, and has gone  
through a far more searching examination; and then the multi-  
plication of titles by the Colleges only added to the confusion.  
What more simple than to make it compulsory for all entering the  
medical profession to enter at one portal, and first obtain a medi-  
cal and surgical diploma, and then, after some years experience,  
take the Physicianship or Fellowship of the College of Surgeons,  
to practise as a physician or surgeon, as he may seem to in-  
cline?"

[The idea of admission to the profession through one portal has  
long been entertained by several ardent medical reformers. Our  
correspondent is in error when he supposes that the "Hall and  
College man" "is the only legal practitioner." According to the  
Medical Act of 1858, the graduate of a Scotch University who also  
holds the diploma of a College of Surgeons is as legal a practi-  
tioner in any part of the United Kingdom as a Hall and College  
man. It may also be fairly questioned, whether our correspondent  
acts in good taste in endeavouring to disparage the Scotch Uni-  
versity degrees for the purpose of exalting the Hall license—and  
whether, indeed, his statement of the relative merits of the exa-  
minations is correct.—EDITOR.]

M. BAZIN thus defines a parasite:—"We give the name of parasite  
to an organised being, vegetable or animal, which, when fixed on  
another being, draws from it the elements of its subsistence."

# General Remarks

ON THE

## PRACTICE OF MEDICINE.

BY

P. M. LATHAM, M.D.

### THE HEART AND ITS AFFECTIONS, NOT ORGANIC. (*Continued.*)

#### IV.—*The Frequent Pulse at its Lowest Degree of Significance.*

It is a fallacy to conceive that disease, as represented by its symptoms, is difficult to know and to treat in proportion as it is a thing of more danger and severity and altogether more extreme. The contrary would be nearer the truth. In the cases which have been considered, the symptom of the frequent pulse, as the single representative of the disease and of the vast peril involved in it, and as the single indication of what is to be done to save life, if life can be saved, was comprehended in all its bearings at a glance. But, in the vast majority of cases, this same symptom will be found less salient, and therefore more to be searched after; less standing alone, and more one of a multitude, and therefore needing to be compared, contrasted, and weighed with other symptoms, before its value can be ascertained. For, indeed, it always has a value, small or great, though it be a variable value in different cases of the same disease, and variable, too, in the same case at different times. These are things not to be seen through at a glance, but contain matter for patient thought to work upon.

Now, as we have hitherto dwelt upon the class of cases in which the frequent pulse is at the greatest and highest computation of danger, so we will next touch upon the class in which it is at the least and the lowest, and reserve for our last consideration the class which is intermediate between the two. And this last we shall have a better chance of understanding aright by previously knowing the two extremes.

Take twenty cases, and let the symptoms in each be characteristically different enough to show that they represent twenty several forms of ailment or disease; but let all the twenty have one symptom in common, and let that be the frequent pulse. Such are realities which are presenting themselves day by day to the experience of physicians. Further, let the symptoms differencing the nature of the ailment or disease in each particular case be so little severe in any, and the one symptom common to all—viz., the frequent pulse—be in all so little above the natural standard, that no apprehension is felt about any single case from first to last; and all the twenty do, in fact, according to anticipation, come to a favourable result. And such, too, are happy realities familiar to our experience.

Now what is it which makes the number of the pulse worth the reckoning in such cases as these,

that we should take so formal an account of it as we probably should and ought to do in our daily intercourse with the sick? Perhaps some of us might not easily be got to trouble ourselves about the meaning of a symptom which occurred in twenty patients, all of whom got well, as we expected they would, be its meaning what it may. But the frequent pulse, as the accompaniment of disease, is never without a meaning; and, whether it be of great or small degree, whether it denote a great present danger or no danger at all, its meaning is always the same in kind. In all these twenty supposed cases, the pulse, being a little above the standard of health, denoted that the disease was making itself felt by the nervous system. In none did it represent any present peril; but in all it contained the germ capable of possible increase to the greatest magnitude and the greatest danger.

There are other things belonging to feeling and function, in our vital economy, which follow the analogy of the frequent pulse in this respect, that whether they be much or little, or great or small, they preserve the same meaning in *kind*; yet, according to their *degree*, they notify and prepare the way for very different results, even as different as life and death.

Hunger and thirst may amount to nothing more than a little sense of physical impatience, natural, wholesome, and not unpleasant to feel, about dinner-time; or they may reach the fierce craving which is ready "to demolish stone-walls". But they are the same hunger and thirst, after all. The first are the hunger and thirst by which we live; the last the hunger and thirst by which we perish. And it is the chief business of our lives to provide that the first become not the last; and every day we are acknowledging practically the possibility, though we have neither thought nor fear about its being realised. Nevertheless, we do sometimes find it realised in single instances of shocking notoriety. And the fate of large armies in war, and of some smaller "armies of martyrs", missionaries for man's enlightenment or for God's truth, shows that hunger and thirst should be the care of nations and governments, and that they who put human life to its hardest uses should study to preserve it.

The same may be said of pain. There is the pain which scarcely disturbs the equanimity of a child, and there is the pain which kills; and the first contains the germ of the last.

#### *The Frequent Pulse of Acute Inflammation in the Strong and previously Healthy.*

There are diseases, then, almost too much for medicine to combat with, and diseases almost too little for medicine to care about; and the frequent pulse is an ingredient of both. In the former, it is the one ingredient which is the very gauge of their formidable character; in the latter, it is that which should at least always prevent us from regarding them with indifference. But there are many diseases far less appalling than the one class, and less trivial than the other, which hold their place between the two, and have a greater practical interest than either. They are uncertain enough in their event to keep both hopes and fears alive during their progress, and amenable enough to remedies to encourage and reward the study of a whole life how to use those remedies aright. These many diseases

have still the pulse, and its qualities and number, to present as chief objects upon which such practical study can be profitably bestowed.

Let the patient be in the prime of life and health, and let his disease have nothing specific or malignant in it, but proceed from some common accidental cause, such as exposure to cold, or mechanical injury, or a blow; also let the inceptive rigor or chilliness be past, and the disease have now plainly declared itself, both what it is and where it is—in fact, that it is acute inflammation in some vital organ. And now, before the disease has had any treatment to interfere with it for good or for evil, or to alter it in any way, the pulse will denote the morbid action in which the blood and blood-vessels are engaged by its new quality of hardness, and the sympathy of the nervous system by the increased number of its beats.

Recollect, it is assumed that the patient was previously in perfect health and the prime of life. At this stage, when the great trial of the constitution from the disease and its treatment is yet to come, the pulse will be more or less frequent from a given amount of inflammation, according as it occupy a part more or less nearly allied with the nervous system by sympathy. To speak generally, the pulse will from the first be more frequent when the inflammation is of the organs within the abdomen, than when it is of the organs within the thorax. Moreover, the inflammation, though just emerged, will produce a greater frequency of the pulse according to its extent; and if its extent be very great, and the part it seizes upon be in close sympathy with the nervous system, the coincidence may even be fatal. Strange events occur in the course of a long experience, taking one by surprise at the time, but, when duly considered, finding their place in the order of things to which they naturally belong. I have seen, in the young and robust, inflammation (apparently common inflammation) seizing upon the peritoneum, and the pulse at once becoming countess and almost imperceptible, and rapidly sinking into death; and examination has disclosed the disease pervading the entire surface and every flexure and fold of the membrane. And still it has been in its earliest stage. The membrane has been entirely injected with red; but scarcely a trace of fluid or of lymph—the proper products of inflammation—has appeared upon any part of its surface or in its cavity.

But to what order of things does such an event as this naturally belong? Truly it belongs to the same order with those two remarkable cases already cited. *There* the disease was in its germ or first development; but already the nervous system felt it, and was overwhelmed by it. *Here* the same event is brought to pass in the same way. *There* the disease partook of a specific poisonous quality, pus-poison in the one, scarlatina-poison in the other mingling with the blood. *Here* it is of the nature of common inflammation; but its vast extent and the part it occupies are equivalent for evil with a malignant quality. It is no figure of speech, but a literal expression of the fact, to say that the disease destroys itself and destroys life at the same time.

This is a most rare event of inflammation, yet much too interesting not to fix our attention for a moment. Well, but suppose the inflammation acute,

and the reaction complete and vigorous, there will be found wrapt up together in the same pulse these two cardinal symptoms—a quality of hardness, representing the disease; and a more frequent beat, representing how the constitution bears it. Such an inflammation will require remedies of much force; and, at every stage and step of the treatment, the pulse will still denote by its quality the need of the remedy, and by its number the power of bearing it. Let *venesection* be the remedy. Upon every use of it, a very strict judgment must be held upon its immediate effects; and that judgment is still to be centred upon the pulse. What *now* of its hardness, which called for the venesection? What *now* of its number, which said that the constitution would bear it? If, an hour or two afterwards, the pulse has lost much of its hardness and many of its number, then assuredly the venesection has told remedially upon the disease, and not hurtfully upon the constitution; and, should it return to its former hardness and its former number, venesection may be employed again. After the second venesection, the like strict judgment must be directed to the same points; and, should the pulse again show an abatement of its hardness and its number diminished, then has the venesection again fulfilled its immediate purpose of good, with no contingent evil.

I cannot determine how often venesection may be safely repeated as a remedy for acute inflammation, the hardness and the number of the pulse thus rising and falling in constant harmony with each other. But as soon as that harmony ceases to be maintained, or is much disturbed; as soon as, whether it be after a first or second or third venesection, the pulse, while it has lost its unwonted hardness, is found to retain its unwonted number, or to have it increased, even greatly increased,—henceforth venesection will become a very doubtful or an absolutely forbidden remedy. Thus far it has exercised a salutary check upon the inflammation. And the hard pulse reduced to softness testifies as much. But it is now beginning to have, or it has had already, some hurtful influence upon the powers of life, or upon the nervous system; and the pulse, remaining as frequent as it was, or becoming still more frequent, is sponsor for the fact.

Now at this point the inflammation may cease altogether; and there may be no further need of remedies properly antiphlogistic, either great or small. The last depletion brought it to an end, and so did its work upon the disease well, very well. But it would have done it work, upon the whole, better, much better, if, in carrying off the disease, it had not left the pulse as frequent or more frequent than when the inflammation was present and progressive. The thing may be of no consequence when we have constitutions naturally vigorous and healthy to deal with; only, in now reviewing the treatment, our just judgment of it must be, that we have pushed our great remedy a little further than the necessity of the case required. But the inflammation may not cease at this point; it may still call for treatment. And the treatment of the inflammation now making progress, with a pulse of more frequency and less power, is no easy task. Of this something may be said hereafter. At present, let it be further remarked, that not only when we use venesection, but when we take blood in any way, whether by venesection, or cupping, or leeches; and, moreover, not

only when we bleed, but when we seek to arrest a rapidly progressive inflammation by a rapidly impressive remedy, be that remedy what it may, whether mercury, or tartar emetic, or colchicum,—the number of the pulse still mediates between how much is needed and how much can be borne. It balances between the force of treatment, as bearing salutarily upon the disease on the one hand, and as bearing hurtfully upon the nervous system and the powers of life on the other. And yet it is not the number of the pulse taken absolutely. It is not any certain number; but its number as it is increased, or is diminished, or remains the same, day by day, under the working of means and agencies powerful alike for good and for evil.

*The Frequent Pulse of Acute Inflammation in the Weak and Cachectic.*

But inflammation does not befall the young and strong exclusively; it is much oftener found in the weak and cachectic. In them, too, it is more generally incident to all periods of life, and comes from slighter provocations of injury and accident from without. Indeed, its connexion with any external exciting cause at all is, in the weak and cachectic, frequently so slight, so uncertain and unapparent, that we are led sometimes to deem it altogether spontaneous and engendered from within, and coming direct from the pravity of the constitution itself.

Now it is a general truth that, in these weak, these cachectic and often seemingly spontaneous inflammations, the frequency of pulse begins earlier and abides longer, and runs up to higher degrees, than in the strong and healthy; or (to look through the sign to the thing signified) the sympathy of the nervous system and the trial to the powers of life are now felt sooner and more constantly, and are carried to greater extremity.

Now, for brevity's sake, let us use the terms "inflammation of strength" and "inflammation of weakness"; for a little more must yet be said of both in their contrast with each other, if we are to get at the true meaning of the frequent pulse in connexion with either, and gain from it all the help it can give us in their treatment.

In all that anatomy discloses after death, and, if the part affected be within reach of the ear, in all that auscultation teaches during life, the inflammation of strength and the inflammation of weakness are the same thing; no mere anatomist or auscultator can tell which is which. But the same treatment which saves in the one case will kill in the other; for their treatment is determined, not by the conditions in which they agree, but by those in which they differ. Now they agree in all that is organic; they differ in all that is vital. What is organic consists in what can be seen, heard, or dissected. What is vital consists in what is felt and acted, and in modes and degrees of feeling and action—preeminently in pain; preeminently in fever and its attributes of cold and heat and perspiration; and preeminently, and above all, in the movements of the heart and arteries, the qualities and number of the pulse.

It is remarkable how health and strength can entertain inflammation, and go through with it, and yet show few or no signs of being vitally hurt by it. I have seen a few cases of inflammation requiring bloodletting, and giving its characteristic hardness

to the pulse, where the number has not been increased a single beat beyond the ordinary standard. Indeed, where there are health and strength, while the inflammation denotes its severity by the force of the remedies needed, the number commonly falls short of 100, and seldom exceeds it. But where there are cachexy and weakness, though the inflammation appertain to no part in strict alliance with the nervous system, the number of the pulse is commonly very frequent throughout. It often rises at once to 120, and in the end it often exceeds it.

Thus strength seems to answer the stimulus of inflammation vigorously, but temperately. It puts its characteristic hardness into the pulse, without greatly multiplying the movements of the heart and arteries. It feels the disease, and bears it well. But weakness seems to answer it with (at most) only a show of vigour, and impatiently. It may give something like its characteristic hardness to the pulse, but not without multiplying exorbitantly the movements of the heart and arteries. It feels the disease, and bears it ill.

But the inflammation of strength and the inflammation of weakness, albeit they are by nature the same things organically and different things vitally, may, by force of accident and circumstances, become *vitality* equalised and the same.

The inflammation of strength is very liable to mischance in respect of its treatment. Opportunity is lost; and when a severe and rapidly progressive disease needs a severe and rapidly impressive remedy, opportunity is very precious, and the loss of it may be the loss of everything. Many a fine robust fellow have I seen who has suffered acute inflammation of an internal organ two or three days without seeking or without being able to procure medical aid; and then, when he has procured it, his disease and its treatment have become a puzzle, from the conflicting indications which have arisen in the meanwhile. Three days ago, a venesection would probably have arrested the inflammation, and the patient have been safe by this time, and in a fair way of recovery; but now, if venesection be adopted, it has been because present symptoms have made us rather afraid to omit it than ready to use it. There has still been an inflammatory hardness in the pulse; but, to set over against it, there has been great frequency. There has been enough of heat and enough of seemingly vigorous action still remaining; but, to set over against them, there has been too much of nervous sympathy, too manifest a trial of the powers of life already begun.

Well, venesection has been adopted; and, happily, it has been just in time. It has abated the hardness and diminished the frequency of the pulse, and raised the nervous system and the powers of life. And thus the inflammation has reclaimed the characteristics of the constitution to which it belongs, and been still the inflammation of *strength*.

Or venesection has been adopted; and, unhappily, it has been just too late. It has taken the hardness out of the pulse, but it has greatly augmented its number. Also it has sunk the nervous system and the powers of life. The inflammation has lost the characteristics of the constitution to which it belongs, and become the inflammation of *weakness*.

But the inflammation of strength has been turned into the inflammation of weakness in other ways than by unavoidable mischance. Among the perils

of disease we must not refuse to reckon the errors of physicians. And this truth has had its instances and its proofs when inflammation was to be treated by venesection or some sort of bloodletting. The choice of the remedy, and its time, and its measure, and its iteration, whether often or seldom, or not at all, are confessedly among the difficult things of medical practice; and he must be either very self-complacent or very oblivious who cannot call to mind that herein he has ever fallen into mistake. Amid many possibilities of error, it would be strange indeed to be always in the right. Nor among the perils of disease must we refuse to reckon the interference of friends with its treatment; and this, too, has been seen when inflammation has had to be treated. And, in charity to human feelings, it is hard to blame them. They see a perilous disease and a perilous remedy. They cannot restrain their anxiety. But it is unfortunate when they show it by distrustful questionings at every turn of the disease and on the use of every remedy; thus always aggravating to the physician his sense of responsibility, at the hazard of overruling his judgment, and of withholding him from doing the full measure of what is right. And too often this has been the sad result. What might have been wholly remedied has been only half remedied; and what has remained has been far less tractable now that it is allied with weakness instead of strength. In truth, there is nothing in practical medicine harder to deal with than this inflammation of weakness, whether it be natural weakness, or the weakness of circumstances and accident, or strength abused into weakness by the fault or mischance of medical treatment. It is all practically the same thing, however it come to pass.

Let it be remembered, however, that our subject is not inflammation and its treatment, but frequency of the pulse. Yet this frequency of the pulse was not to be understood in its pathological significance, otherwise than by our becoming acquainted with it in those diseases which display it most conspicuously. Such are fevers and inflammations. For in them the nervous system is most largely engaged. And the nervous system, for the share that it has and the part that it plays, has its surest index and measure in the number of the pulse.

Already, as to the inflammation of strength, we have gone so far into its treatment as was needed to show the number of the pulse guiding and regulating it. And just thus far, and with the same intent, we will now touch upon the treatment of the inflammation of weakness.

In the inflammation of strength and its treatment, we showed the number of the pulse arbitrating between the curative and hurtful effects of great remedies, sanctioning their use up to a certain point and no further, and thenceforth forbidding them. We followed the treatment so far as, under this safeguard, the operation of these remedies was successful. But we ceased to follow it, when the inflammation was found still to continue, and the pulse becoming more frequent no longer sanctioned the use of the same remedies for its cure; when, in truth, the inflammation has assumed the characteristics of weakness, and required another treatment, but still under the same safeguard. For in the inflammation of weakness, as in the inflammation of strength, the number of the pulse does not directly

suggest the use of any remedy or any mode of treatment; but here as there it still serves for an arbiter. Here as there, when other indications have pointed directly to the remedy or mode of treatment, then it sanctions, or forbids, or moderates their use.

Let it always be borne in mind that the progress of inflammation within the part from one stage to another, until it reaches irreparable disorganisation, need not be less rapid when allied with weakness than when allied with strength. It does not move slower, because it moves with less force. And thus it calls as much as ever for a remedy and requires as much as ever that the remedy should be seasonably applied. Only the direct and immediate aim of the remedy is now different.

The ultimate aim of all treatment is indeed the same. Whether the disease be one of weakness or of strength, be acute or chronic, be common or specific, the end and aim is to cure it. But immediately treatment has to do with many an aim which is not the end itself, but only conducive to the end.

When there is much and unremitting heat of skin, and the pulse is hard and yet but moderately frequent, and the vascular system and the nervous system are strongly and steadily reacting, and all that moves and all that feels within the man are (so to speak) doubly alive, then, the fact and the seat of the internal inflammation being once ascertained, it is less absolutely necessary for the success of our treatment to go into its particulars. It is enough, for the present to take the inflammation in its largest sense, without noting its stages and its consecutive phenomena from day to day or from hour to hour. For now the remedy has a less concentrated aim. The indications of treatment are more diffusive and general.

But in proportion as the heat of skin is less sustained and less in degree; and the vascular system, and the nervous system, and all that moves, and all that feels, show less of reaction and less of life, and the pulse is less hard and more frequent, then we have the more need to be acquainted with the exact seat and stage of the inflammation and all its organic conditions; and its shiftings and movements from day to day; its advancing, or receding, or standing still. For now the treatment is more and more drawn towards the part, and more concentrated in its aim.

Between no display of strength in the constitution at large and extreme weakness; between no notable sympathetic reaction and vital surrender and collapse, there are many states and degrees; and the progress, the rapid progress, of inflammation in the part is compatible with them all.

VACANCIES. The following appointments are vacant:—medical officer and public vaccinator for the Clonmel Dispensary district of the Clonmel Union; medical officers for the Newcastle-under-Lyme district; for the Hanbury district of the Droitwich Union; for the parish of Kirkowan, Wigtonshire; for the Colbridge Dispensary district of the Colbridge Union; for the Clifden Dispensary district of the Clifden Union, county Galway; for the Claudy Dispensary district of the Londonderry Union; ophthalmic surgeon to the Aberdeen Royal Infirmary; to the Bellaghy Dispensary district of the Magerafelt Union, county Londonderry; for the Cleckheaton district, North Brierly Union, Yorkshire.

## Clinical Lecture

ON

### THE SUCCESSFUL USE OF IODIDE OF POTASSIUM IN THE TREATMENT OF ANEURISM.

BY

WILLIAM ROBERTS, M.D.,

PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY.

[Reported by MR. E. DAWSON, Clinical Clerk.]

GENTLEMEN,—I propose to draw your attention to-day to a case of thoracic aneurism, which has been under my care, in No. 68 Ward, for the last six weeks.

The case affords an advantageous example for the illustration of the various points of importance in the diagnosis of aortic aneurism; but I shall pass over these with only a brief recital, in order to bring before you at length certain points of interest bearing on the use of iodide of potassium in the treatment of aneurism.

J. P., a collier, aged 39, unmarried, was admitted into the Royal Infirmary, on October 6th, 1862, complaining of pain in the chest, a troublesome cough, and difficulty of breathing at night. He stated that about four months ago, when in a state of intoxication, he was kicked in the chest by a policeman. From that time he has been subject to paroxysms of excessively severe pain, persisting for several hours at a time, in the back, neck, and running up to the left side of the head and left shoulder. He compared the pain in the latter situation to having pieces of his flesh torn out. There has not been hæmoptysis at any time. About two months after the above occurrence, he observed an unnatural prominence of the upper part of the sternum.

When admitted, the patient had the appearance of good health; the pulse was 96, and the respirations were 22 per minute. The superficial veins of the upper arms, and the external jugulars were somewhat distended; the right radial pulse was slightly feebler than the left. The speaking voice was unaltered, but the cough-voice possessed the peculiar stridulous character distinctive of interference with the function of the recurrent laryngeal nerves.

The pupil of the left eye was motionless from previous accident, the right pupil was natural. There was some dysphagia—when the chest was uncovered, the first bone of the sternum and its immediate vicinities were observed to be bulged out, and to be the seat of a heaving pulsation. On the left side of this prominence, in the second intercostal space, close to the sternum, there was a soft pulsating elevation standing out about a quarter of an inch above the surrounding level. This elevation was conical in shape, and had a base about the size of a shilling. The heart's apex beat in the fifth interspace within the nipple line.

Percussion revealed a considerable area of diminished resonance over the bulging parts. Transversely, in the level of the second interspaces, the dulness measured four inches and a half, extending more to the left than the right of the middle line; vertically, there was dulness for three inches and a half below the sternal notch. There was no fullness or pulsation in the last named spot. The cardiac sounds were normal over the pre-cordial region; they were loudly audible over the seat of dulness above described.

The first sound was faintly murmurish over the soft elevation; and a distinct though faint systolic murmur

existed in the course of the innominate artery; this was intensified over the right carotid and in the acromial angle. No murmur existed over the left carotid and sub-clavian. With such an array of symptoms and physical signs, the diagnosis could not remain for a moment doubtful. The case was one of aneurism of the arch of the aorta making its way forward through the parietes of the chest.

On October 10th, the patient was ordered to take five grains of iodide of potassium three times a day; to keep his bed; and to restrain as much as possible the quantity of liquids taken in the way of drink. Three days later the iodide was increased to seven grains and a half three times a day. Six days after the commencement of the treatment, the patient reported himself a great deal better; the paroxysms of pain no longer recurred; the cough and difficulty of breathing were less troublesome; and the soft pulsating elevation was slightly less prominent. The physical signs remained otherwise unchanged. The iodide was now increased to ten grains three times a day.

From this date (October 16th), to October 27th (a period of eleven days) the patient went on favourably. He continued free from pain, difficulty of breathing, and dysphagia; and the soft elevation had almost altogether subsided to the level of the surrounding parts.

He was now allowed to get up, and the restrictions as to fluids were relaxed. The iodide was increased to fifteen grains three times a day.

On November 4th (twenty-fifth day of treatment), the dulness measured four inches across, and two inches and three-quarters vertically. The dose was now raised to twenty grains.

On November 18th (thirty-ninth day of treatment), the area of dulness was carefully measured again. It had now contracted to three inches and three-quarters transversely, and two inches and a half vertically; so that from the commencement of the treatment, it had diminished three-quarters of an inch in one direction, and one inch in the other. The soft elevation had sunk to the level of the surrounding parts, and had become wholly inappreciable to the eye. Pulsation was still felt over the spot. The patient was free from pain and difficulty of breathing, and felt himself exceedingly well. The cough was still stridulous in character, and the veins of the neck and upper arms were not perceptibly less distended. The inequality of the radial pulses had not disappeared.

This is the sum of the improvement after a treatment of six weeks; and it is certainly a striking result in so unmanageable a disorder as a protruding aneurism of the arch of the aorta.

[Since the delivery of this lecture the patient has continued the use of the iodide of potassium up to the present time (Dec. 23). An obstinate diarrhœa necessitated the diminution of the iodide to five grains three times a day. The bulging of the first bone of the sternum is conspicuously less, and the limits of dulness correspond to the following dimensions: transversely, three inches and a half; vertically, two inches and a quarter.

The state of the radial pulses, and of the superficial veins of the neck and arms, together with the character of the voice, remain unaltered; and there is decided emaciation.]

I will now relate to you the history of two other cases, within my knowledge, of aneurism treated with iodide of potassium.

About a twelvemonth ago, I saw in consultation with Mr. T. Windsor, who first called my attention to this mode of treating aneurism, a lady, 29 years of age, suffering from an undoubted aneurism of the arch of the

aorta, implicating the commencement of the arteria innominata. There were violent pains on the right side of the head, paroxysmal dyspnoea, excessive pulsation at the root of the neck on the right side, and sleeplessness. A dull space extended from a little to the inside of the right sterno-clavicular articulation for a distance of two inches outward. Over this space there was a heaving pulsation. No murmur existed with either sound; but the sounds were intensified over the arch, and towards the clavicle. Repeated slight hæmoptysis had been observed.

For an account of the further progress of the case, and the treatment, I am indebted to Mr. Windsor.

In the succeeding six months the condition of the patient became steadily aggravated in spite of a persevering observance of the recumbent posture and a regulated diet. On several occasions the voice was temporarily lost; in addition to some dysphagia, there was constant troublesome cough, with tenacious scanty expectoration, and occasionally severe paroxysms. The difficulty of breathing and pains were often so severe, that the patient was forced to quit her bed, and to walk about. She had become considerably emaciated, and so weak as to be unable to leave her room. The clavicle also began to project, and at length stood out half an inch beyond its natural level. The pulsation at the root of the neck increased; and the right eye became the seat of a severe congestion.

The iodide of potassium was first administered in April last in the hope of diminishing the pains in the head. The desired effect was speedily produced; and the medicine was discontinued after it had been used a week. In July, the patient growing daily worse, and a fatal termination appearing not to be very far off, Mr. Windsor again administered iodide of potassium in doses of five grains three times a day. This quantity was shortly after increased to ten grains; but owing to the occurrence of violent salivation, the dose was again brought down to five grains. This quantity agreed; and the patient has been taking it until the present time, with great benefit, as you shall hear. The general symptoms subsided quickly; the cough, pain, dyspnoea, and dysphagia, disappeared; the occasional hæmoptysis ceased to recur; the patient gained flesh and strength, and two months ago she was able to walk six miles; and, more important than all, the projection of the clavicle progressively receded, until it has now almost gone back to its natural position.

The third case which has come under my personal notice is a patient of my colleague Dr. Wilkinson.

This man was admitted into the infirmary on October 20th, with a thoracic aneurism coming forward in the neck. In a few days, it formed a tumour as large as a child's head, extending on the left side from the clavicle almost to the angle of the jaw, causing very great distress; and passing on to what appeared a speedy termination by rupture. This man was put under gradually increasing doses of the iodide of potassium until the quantity attained was fifteen grains three times a day. No positive amelioration can be said to have taken place in the condition of the aneurism; but the distress is scarcely so great as it was, and the rapid growth of the tumour seems to have been stayed.

[Seventeen days after the delivery of the lecture, Dr. Wilkinson's patient died. Death took place from pressure of the tumour on the left pneumogastric nerve, and consequent pulmonary mischief. The vagus trunk was flattened out and atrophied for the space of an inch and a half in the neck. Only a few nerve-tubules could be discovered in this part by the microscope. The left lung was the seat of several patches of gangrene as large as hen's eggs, surrounded by areas of consolidation. The pulmonary gangrene had been detected a week before

death. The sac of the aneurism was lined with thick layers of coagulated fibrine; and a large firm blanched clot attached by a somewhat broad pedicle to the upper parts of the parietes, floated freely in the sac.]

So far as I know, the first notice of the use of iodide of potassium in aneurism occurs in a clinical lecture of Professor Nélaton (*Clinique Européenne*, July 1859). M. Nélaton had been consulted by a Pole on account of a tumour in the lower part of the neck. Several physicians of eminence, Bouillaud, Andral, Beau, had previously seen the case, and had diagnosed an aneurism of the innominate artery or of the aorta. The patient stated that while residing in Warsaw, iodide of potassium had been administered to him with great relief. Nélaton took the hint, and prescribed the same. To his astonishment, a very notable amelioration followed, which went on almost to complete disappearance of the tumour, and the patient returned to his country in a satisfactory state of health.

In a late number of the same journal (Aug. 27th, 1859), you may find a very brief account of a number of cases by Bouillaud. One was a woman with aneurism of the carotid artery. Iodide of potassium was administered in *gramme* doses; then in two-*gramme* doses for two months. At the end of that time, the tumour, previously as large as a pigeon's egg, had diminished almost to disappearance. The second was an aneurism of the aorta and innominate in a man. The tumour, which had a very considerable volume, had suffered displacement and very great diminution of size under iodide of potassium. The case was under treatment when reported.

A third instance related to a large aneurism at the point of origin of the carotid and subclavian. The tumour had diminished considerably in a few weeks under the iodide.

A colonel with an aneurism of the carotid furnishes a fourth case in which Bouillaud saw the tumour almost wholly disappear after taking the same drug.

The next reference to the subject comes from a wholly independent source, and is, for that reason, of additional value. It occurs in a paper by Dr. Chuckerbutty of Calcutta, published in the *BRITISH MEDICAL JOURNAL* for July 1862. He gives an account of four cases.

The first of these was an aneurism of the innominate artery growing steadily upward into the neck. The growth ceased on the administration of iodide of potassium in decoction of cinchona, and the sac gradually solidified. The patient, however, was carried off, some months afterwards, by an attack of bronchitis. The autopsy revealed a sac as large as a pear, filled with dense coagula, leaving merely a narrow channel on the outer aspect, through which the right carotid and subclavian arteries communicated with the aorta.

In a second case, marked temporary relief followed the administration of the iodide in an immense aneurism of the aorta. The aneurism finally destroyed the patient by rupture. A *post mortem* examination three hours after death showed the sac to be filled with dense, solid coagula.

In a third case of large aortic aneurism, temporary amendment took place so far that the patient left the hospital, considering himself cured. Three months later, he returned, with intense aggravation of all his symptoms, and died in a few days.

In the fourth example, an aortic aneurism which formed a dome-shaped tumour two inches in diameter, coming forward through the sternum, had been treated in vain by turpentine, sulphuric acid, and other remedies. After the administration of iodide of potassium internally, and the application of the tincture of iodine externally, the patient steadily improved in every respect; the thoracic pain disappeared, the swelling diminished, the hæmoptysis ceased, and the patient ate and slept like any other man. He was still under treatment.

I do not wish to make too much of these facts. The erratic course of aneurismal tumours, and the occasional occurrence of spontaneous consolidation of their sacs are well known. Nevertheless, the twelve cases here brought together form a very remarkable series. In all of them, save one, striking relief of suffering followed the use of the drug; in eight, an undoubted diminution of the size of the sac took place; and in a few, complete subsidence of the swelling seems to have occurred.

The cases of Dr. Chuckerbutty would appear to indicate that the beneficial effect of the iodide was owing to its power (hitherto wholly unsuspected) of increasing the coagulability of the blood. Dr. Wilkinson's case lends support to this view; for not only was the sac lined with layers of fibrine, but a very firm, decolorised, fibrinous mass, attached on one side, floated in the cavity of the aneurism. The value of the above observations, as bearing on the conclusion inferred, is greatly increased by the circumstance that they are derived from two distinct and wholly independent sources.

Enough has certainly been advanced to encourage an inquiry into the power of iodide of potassium as a general hæmstatic; and to demand a fuller trial of its effects in internal and external aneurisms; in the treatment of which no internal remedy hitherto employed has succeeded in gaining even a temporary footing.

**USE OF COMPRESSED SPONGE IN THE PREVENTION OF LACTEAL SECRETION.** Dr. P. Stewart of Peekskill, New York, states that three years ago, he reported in the *New York Journal of Medicine* a case of suppression of the lacteal secretion, in the breast of a lady recently confined, by means of compressed sponge and bandage. Since the report of this case, he has several times had occasion to adopt the same practice, and uniformly with the same happy result. If others have used the method it has failed to come to his knowledge, and as the remedy is easily applied, and the results in his hands, at least, uniformly successful, it may be of some little service, he thinks, to call the attention of the profession once more very briefly to the subject. A flat soft sponge, carefully freed from all foreign substances, large enough to cover the entire breast, with a small hole or depression cut out in the centre for the nipple, is subjected to a pressure of a few pounds for a couple of days, and then applied over the breast; a compress is laid over this, and the whole secured by a bandage passed over the shoulders, and around the waist, so as to produce equal and uniform pressure over the entire surface. The bandage should be tightened sufficiently often to maintain a constant pressure for twelve or fourteen days. The best time to begin the treatment is within twelve hours after the birth, when the sponge is best applied dry; but if it is delayed from any cause until the breast becomes tender, and the milk begins to be secreted, Dr. Stewart's custom is to dip it in warm vinegar once or twice a day. (*American Medical Times*.)

## Addresses and Papers

READ AT

### THE THIRTIETH ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

[Held in LONDON, AUGUST 5th, 6th, 7th, and 8th, 1862.]

#### OBSERVATIONS ON THE OCCURRENCE OF MALIGNANT PUSTULE IN ENGLAND: ILLUSTRATED BY NUMEROUS FATAL CASES.

By WILLIAM BUDD, M.D., Clifton; Honorary and Consulting Physician to the Bristol Royal Infirmary.

"Le médecin doit, dans ses premières études, jeter un coup d'œil sur les animaux qui se rapprochent le plus de l'homme."—*Chaussier*. (Adopted from Régnier.)

In France, Germany, Russia, Lapland, Sweden, Italy, and other parts of Europe, under the characteristic name of Malignant Pustule, a disease has long been familiarly known and described, which proves fatal every year to a large number of persons.

Beginning as a minute vesicle, which is seated always on some uncovered part, its special character is to excite a peculiar form of gangrenous inflammation, which, spreading rapidly from the point first affected to the neighbouring tissues, gives rise to local changes of very uncommon aspect, and finally destroys life by general infection.

A disease calculated, by so much that is striking, to arrest attention, has, naturally, been made an object of inquiry by many eminent observers.

Among other distinguished men, Vallisneri, Solander, Pallas, Fournier, Thomassin, Chabert, Kausch, Malacarne, Linneus,\* Glanström, Enaux and Chaussier, Leuret, Delpech, Rayer, Bourgeois, Salmon and Maunory, Hoffmann, and Heusinger, may be specially mentioned as having each contributed something to its history.

\* Linneus, who was himself attacked by the disease, but happily recovered, was the first to give authentic evidence of the existence of malignant pustule in Lapland.

Die Milzbrand-Krankheiten der Thiere und des Menschen. Erlangen: 1850. Some of these authorities I have studied in the

The following important points appear to be established by the investigations of these and other writers:—

1. That the malignant pustule in man is identical with, and derived from, the eminently contagious disease which, under the name of "charbon" (*Germanicé*, "milzbrand", spleen-gangrene) or (in sheep) "sang", has prevailed from time immemorial in various continental countries, in oxen, sheep, horses, and other animals.\*

2. That the disease may be communicated to man from the animal in the following ways:—

a. By direct inoculation, as in the case of butchers, farriers, skinner, herdsmen, drovers, and others, in whom accidental inoculation with it appears to be an event of no uncommon occurrence in the countries where "charbon" is most rife.

b. By means of the skin, or simply by the hair of diseased beasts; modes of communication of which many decisive examples are on record. Also, through contact with the bones, the hoofs, and horns, and the fat and tallow of animals dead of "charbon."

c. By eating the flesh of animals killed while affected with it, as also by using the milk and butter of infected cows.†

d. And, lastly, by insects which have been in contact with the bodies or carcases of diseased cattle; a mode of communication obviously difficult to demonstrate, but in proof of which numerous cases—some, apparently, entirely free from ambiguity—are recorded.

3. That in the countries where "charbon" prevails, concurrently with the cases of malignant pustule which are the observed result of direct inoculation, other cases occur in which the vehicle of the poison cannot be identified.

4. That these cases have, in common with the rest, this significant peculiarity: that the disease is always seated on some part of the person which is habitually uncovered.‡

original. For my knowledge of the rest I am indebted to Heusinger's elaborate and comprehensive treatise. The three works whose titles are subjoined, and which stand among the first in Heusinger's catalogue, also deserve special mention, as showing how far back the records of this malady go, and at what an early period the disease in man was identified with that in the animal. *Tossi a Serra. De anthrax seu carbunculo tractatus. Vetus. 1576. Chr. Perez de Herrera. De carbunculis animadversiones. Pintia: 1604. Treilo. Lancetta di Pestilenza commune ai bruti e di contagio mortale, dell' uomo. Venezia: 1632. Fol.*

\* Indications of the occurrence of this epizootic extend back to a remote antiquity. Not to mention the murrain described in the ninth chapter of Exodus, by which Pharaoh's cattle, horses, asses, and sheep, were destroyed, and which by most writers is thought to be identical with "charbon" or "milzbrand," Heusinger considers it almost certain that the disease described in the first book of the *Iliad* (l. 49—52), that referred to by Ovid in his seventh *Metamorphosis* (l. 523—600), various epizootics mentioned by Livy and Dionysius Halicarnassus, and lastly that delineated by Virgil in the first and third *Georgics* (l. 464—470) respectively, were of the same nature.

† A remarkable example of the communication of the disease by the milk of an infected cow was related by Chisholm in his account of the epidemic which occurred in Barbadoes in 1795. The malady was rife on the plantation of Mr. Cummin, and carried off more than fifty head of cattle, beside a considerable number of negroes who had partaken of their flesh. While the epidemic was at its height, one of Mr. Cummin's children, a little girl three years old, took one morning for breakfast so much milk that scarcely any was left for the rest. Unfortunately, this milk was furnished by a cow which at the time was suffering from the murrain. Four days afterwards, the child was seized with all the symptoms of the prevailing malady, including malignant carbuncles identical with those exhibited by the negroes who had eaten the diseased meat. Her life was saved with difficulty; and a deep scar on her left arm remained to mark the nature of her illness. (Chisholm, on *Lues Bovina Introtropica*, *Edinburgh Medical and Surgical Journal*, vol. vi, p. 36.) It is remarked by more than one writer, as a curious fact, that, in milk cows, the secretion of milk often continues for a considerable time after the onset of the malady.

‡ The few exceptions to this rule which do occur only add to its significance. Such, for instance, is the interesting case lately recorded in the *Lancet*, by Mr. Harper of Holbeach, in which a man who was tending diseased sheep inoculated the prepuce with his soiled hands. Many instances of this particular accident are recorded by foreign writers. Heusinger relates a case of malignant

5. That in animals, and in oxen especially, the action of the specific poison by which the malady is caused is even more virulent than in man; as shown, in the first place, by a more speedy death; and, in the next, by the more rapid spread of gangrene, and by the extrication on a large scale, while the animal is yet living, of foetid gases in the tissues of the part affected.

6. That the contagious property is possessed in the highest degree by the lymph of the characteristic vesicles; and, next to this, by a peculiar exudation (the so-called "humor anthracicus") which occurs in the cellular tissue of the affected part, in that of various parenchymatous organs, and sometimes, also, in the serous cavities of the chest and abdomen.\*

7. That the malignant pustule, when contracted by man, may be communicated by contagion to other men, or back to the animal by inoculation.

It would be out of place here to give, in detail, the evidence on which these conclusions are founded. I may, however, state that the identity of the malignant pustule with the "charbon" of cattle—already, perhaps, sufficiently established by the countless cases of accidental direct communication, has lately received its crowning proof, in the reinoculation of the disease, with all its specific characters (including the power of indefinite propagation by the same process) from man back to the animal. (*Gazette Médicale*, 1857, p. 684, Salmon and Maunory.)

Some of the facts which show that the virus may be conveyed by the hair of beasts are very striking.

Trousseau, for example, relates that in two factories for working up horsehair imported from Buenos Ayres, and in which only six or eight hands were employed, twenty persons died in the course of ten years from malignant pustule. This distinguished teacher had himself the charge of three cases from the same establishments, in which life was only saved by severe cauterisation. (*Gazette Médicale*, *Fevrier*, 1847, No. 4.)

Rayer states that in the course of three years, while he was attached to the Hospital of St. Louis, he had to treat eight cases of malignant pustule; and adds that all eight came from an establishment in the immediate neighbourhood for the manufacture of Russian hair. (*Traité des Maladies de la Peau*. Article, *Pustule Maligne*.)

I think it is the same writer who records the still more remarkable case of three persons who were all attacked by the disease after cleaning some hair that had for many years served as the stuffing of an easy chair.

Two other facts may be mentioned here, in addition to these, which tend to show that this virus, like the other contagious poisons, when once in the dried state, may retain its powers for indefinite periods of time.

It is stated by Gerlach that some straw on which, three years before, some beasts dead of "charbon" had been flayed, on being brought into a shippen, in-

pustule in the instep, but it occurred in a boy who always went barefoot. In the epidemics which have occurred in the West Indies, when the disease attacked the blacks, who were, indeed, its chief victims, the pustule appeared in the most various parts of the body.

\* Greve believes the virulence of this exudation or carbuncle juice to be much greater while it is yet warm, and immediately after the death of the animal. On this point, he makes the following remarkable statement:—

"Ich sah eine grosse Menge am Milzbrand abgestandener Kühe und Ochsen von Abdeckern abledern, ohne über Folgen für diese; aber sie lederten die Cadaver erkalte ab und ihre Hände und Arme waren ohne Verwundungen. Sobald sie mit verwundeten Händen die noch warmen Cadaver behandelten, trugen sie allemal die gefährlichsten Carbunkeln davon. Furchterlich wirkte das noch warme, gelbe, jauchige, und stinkige wasser in der Bauchhöhle des krepirten Viehes. Alle Hunde die davon aufleckten krepirten fast auf der stelle. Ich spritzte ein paar Tropfen dieser warmen Jauch in das Auge einer Taube, und 3 Stunden nachher war sie todt, ebenso ei ne Ente welcher ich ungefähr einen Theelöffel davon in den Halseergus. (Greve, *Erfahrungen und Beobachtungen*, i, s. 48.)

fectured with the same disease the sheep that were folded in it.\*

In Caspar's *Wochenschrift*, Nicolai gives the history of a tanner who died of malignant pustule of the face. After full three months, the daughter of this man; and then her brother died of malignant pustule also. (Caspar's *Wochenschrift*, 1833, p. 268.)

The propagation of the disease by flies which have previously been in contact with animals affected with charbon appears to be equally well established. As this, however, is a point to which I shall have to return, I will not dwell further on it here.

Whatever the way in which the pustule may have been contracted, one thing appears certain, and that is, that in man, in the immense majority of cases, it is at the onset local only; the general poisoning which ensues being due to the after diffusion of the morbid changes and products engendered in the part first affected.†

This capital point in its pathology may be inferred not only from the order in which the morbid phenomena succeed one another, but still more clearly from the decisive fact that the early destruction of the diseased part by caustic not only often prevents the development of the constitutional disorder, but in many cases issues in perfect and immediate cure.‡

The history is, in short, that of a specific animal virus, which, implanted by inoculation in a given part, sets up there a series of malignant zymotic changes, which are propagated thence to the whole system.

From this summary it will be seen that this remarkable disease has not only been closely studied by a great number of continental naturalists and physicians; but that their published observations upon it amount to a considerable body of medical literature.§ This being the case, it is certainly a very curious fact, whatever the explanation, that the profession in England are almost entirely silent on the subject.

Among systematic writers, Dr. Craigie, in his *Practice of Physic*, Mr. Druiitt, in his *Vade Mecum*, and Dr. Copland, in his *Medical Dictionary*, are, as far as I have been able to ascertain, the only English authors who have treated of the disease at all. All three speak of it as being all but unknown in England; and all three professedly derive their account of it from the French.|| In the long list of writers on malignant pustule which are appended by two of these authors to their respective articles on it, no English name appears.

With the exception of two cases of which Mr. Lawrence gave an account in a clinical lecture published some twenty years ago; and of a valuable series since related by Mr. Harvey Ludlow, there is, I believe, no description of the disease, drawn from actual observation, by any British practitioner.¶

\* Gerlach, Die Blutsuche der Schafe in Rücksicht der Ursachen. *Magazin f. Thierheilk.* B. xi und xii. See Heusinger, p. 62.

† I say "in the immense majority of cases," because in some few instances in which the disease is caused by the ingestion of infected flesh or milk, the poison becomes absorbed at once into the blood, and leads to a general infection which precedes any local mischief.

‡ See for evidence of this Bourgeois's able paper in the *Archives Générales de la Médecine* before referred to. The testimony of all the best observers is unanimous as to this point.

§ Heusinger quotes more than four hundred authors who have treated, either of malignant pustule or of the corresponding disease in cattle, or of both.

|| I do not mention Chelius's *System of Surgery*, because that may be said to be only a German book in an English dress. It contains, however, a brief but clear account of malignant pustule, with some notes added by the translator.

¶ Mr. Ludlow's paper, which appeared, in September 1852, in the *Medical Times and Gazette*, under the title of Carbuncular Inflammation of the Lips and other parts of the Face, and of whose existence I was not aware at the date of the present communication, does not appear to me to have received the attention it deserves. The paper opens with the following passage:—

"The disease which forms the subject of consideration in the following pages belongs to a class whose diffusion has been pretty steadily increasing in this country during the last five years. Before

From this one of two things is clear; either that a malady which is unlike any other, and which, in all respects, is one of the most remarkable to which man is liable, has hitherto escaped general recognition here; or that, as Mr. Druiitt and Dr. Copland suppose, malignant pustule (except, perhaps, as a thing of extremest rarity) is never met with in England. This last alternative, if true, would be very difficult to explain, inasmuch as the epizootic from which malignant pustule is derived, so far from being unknown here, has, from a very remote period, caused every year a large mortality in English live stock.\*

The "joint murrain," "black quarter," or "quarter evil," and the "blood" (the name by which the malady is known in the sheep), are the same diseases as the "charbon," "quartier," and "sang" of the French, and the "milzbrand" of the German writers.

That a disease which is known to be communicable to man should prevail in this country, and yet never be communicated to him, would be a strange, if not an unaccountable thing.

The fact, I believe, is not so. If my own experience may be trusted, the only reason why malignant pustule has been so rarely noticed by English writers is that, except by one or two observers, it has hitherto been confounded with other maladies which offer some points of analogy with it.

In the month of October 1856, I saw a case which presented all its characteristics in the highest degree, and which ended fatally on the seventh day. Since then I have been informed of twenty-three other instances of it. Of these twenty-three, two were seen by myself, and six others by intimate friends who have kindly favoured me with their notes.

That so many cases should have come, within so short a period, to the knowledge of a single practitioner, shows, at any rate, that it is high time we should all take serious note of the presence of this disease among us, and prepare ourselves to deal with its terrible emergencies.

[To be continued.]

that period, it appears to have occurred quite sporadically, and at have been amenable to ordinary treatment. Hence, our medical literature offers but few original observations on the subject, the knowledge we possess of it being derived chiefly from continental authorities. Charbon and malignant pustule, indeed—diseases with which French surgeons are so familiar—present broad features of similarity to the affection which the accompanying cases are designed to illustrate; and although some trifling differences exist between them, yet the resemblance of their distinctive characters is evidently so close as to compel us to include them in the same class, and to place them in the same pathological light."

Although Mr. Ludlow hesitates actually to identify the disease he describes with the true malignant pustule, it is plain, from this passage, that he had a strong conviction of the close analogy between them. In the concluding part of his paper, he sums up his views as to the causes of the malady in the following words:—

"From a consideration of all the cases which are recorded in the journals, or have occurred during the last two years at the hospital (St. Bartholomew's), I think the disease may be attributed to three main causes. 1. The direct inoculation of a poison, animal or vegetable. 2. The inspiration of air tainted with such poisons. And 3. Feeding on unhealthy food."

The cases reported by Mr. Ludlow, to the number of six, are all characteristic examples of malignant pustule.

\* The epizootic described by Matthew Paris as having been so fatal to cattle in England in 1252, was, probably, an epizootic of the disease in question. He relates that dogs and ravens which fed on the carcasses of the infected cattle rapidly died in consequence, and the panic among men was so great that for the time the use of beef was given up. The following is the *verbatim* account:—

"Ejusdemque anni curriculo, post multa aestatis caumata, tempore adveniente autumnali, facta est tanta pestifera armentorum mortalitas pluribus locis in Angliâ, precipuè autem in Northfolc et in Meriscos, et paribus Australibus, quantum nullus se meminit previdisse. In quâ peste hoc evenit mirabile, quod de pecorum mortuorum cadaveribus, etiam canes et corvi qui vesebantur, illico intumuerunt et infecti obierunt. Unde nullus erat hominum qui carnes bovum comedere auderet, ne forte ipsæ essent de morticinis memoratis." (*Historia Major Matthæi Paris. Editore, Willielmo Watts, S.T.D. Londini: 1648. P. 847.*)

## HOSPITAL PRACTICE:

METROPOLITAN AND PROVINCIAL.

### ST. BARTHOLOMEW'S HOSPITAL.

CONGENITAL INGUINAL HERNIA, WITH DOUBLE STRANGULATION.

Clinical Remarks by JAMES PAGET, ESQ.

A MAN, aged 31, was admitted into St. Bartholomew's Hospital, November 30th, 1862, under Mr. Paget's care, for strangulated inguinal hernia on the right side. He was a waiter, generally healthy and strong; and, so far as he knew, never had any swelling in the groin until a few days before his admission. On the 24th, six days before he was admitted, he slipped off some steps, and fell astride on them. He felt little or no pain from the accident, a slight and transient feeling of nausea being the only discomfort; and he soon thought no more of the matter. At 6 A.M., however, on the following morning, he began to vomit, and all the food and drink that he took were returned almost immediately. This sickness continued throughout this and the following days, up to the time of his admission into the hospital. The bowels were very slightly open four days before admission, and not since; on the same day he first noticed the hernia, but thought little of it, and did not mention its existence to the surgeon who attended him. He had taken a considerable quantity of medicine, probably aperient, before he came to the hospital.

The hernia was flask or pear-shaped, with a long neck, and occupied the right side of the scrotum, and the inguinal canal. It measured about four inches in length, by one inch at the neck, and two at its widest part. It was somewhat tense, but not very tender, and the integuments covering it, though rather red, were otherwise perfectly healthy. At the lower and wide part, the hernia felt soft and elastic, as if containing fluid or fluid and intestine, while the neck was hard and resisting as if entirely or chiefly solid. On coughing or straining a wave of impulse extended down the inguinal canal to the external abdominal ring, but here it stopped short, and no motion was communicated to any part of the swelling beyond this point. The abdomen was not tender, but somewhat distended; and the outlines of distended coils of intestine were very distinct, the appearance being pretty general, and not confined to any particular part of the abdomen.

He looked thin and somewhat pale, but rather like one who is so habitually, than as if he were distressed by the disease. His countenance was tranquil, his voice and manner apparently quite natural, and he complained of no pain. Pulse rather quickened, but of good volume and strength. Breathing about natural. Tongue moist, etc.

After a slight attempt at reduction, under chloroform, Mr. Paget proceeded to operate by making an incision over the upper part of the sac and external ring. The sac was then opened, and found to contain some small intestine, but no fluid. The intestine was of a dim scarlet colour and rather velvety from congestion, but it was nowhere darker than this, and the coats, though very thick, seemed perfectly sound. The walls of the sac were very thick, and its internal surface was of an opaque yellowish white colour, and superficially wrinkled like the internal surface of a large and aneurismal artery. A stricture in its neck was found at the external ring, and divided; but, the intestine being still confined at the lower part, the incision was prolonged downwards

through the sac and superficial structures for another inch, and it was then discovered that a second strangulation was caused by an irregular contraction and thickening, about two inches below the external ring—at about the part where the long neck began to expand into the body of the hernia. On dividing this second stricture, a considerable quantity of yellowish and nearly clear fluid gushed out, and the intestine, which had been protruded into this part of the sac, could be readily drawn up. It was, for the most part, in about the same state of congestion with the portion just described; but, at the part which had been gripped by the lower stricture, there was a very distinct "nip" about an inch long, by one-eighth wide, extending transversely across part of the circumference of the bowel. The coats seemed still sound at this part; but close to it was a small round blackish-brown spot, of about the size of a split pea, surrounded by a narrow white areola; the consistence of the bowel was not here, however, evidently impaired. The intestine was therefore returned into the abdomen.

The lower part of the sac proved to be the truncalis vaginalis testis, with healthy texture and condition of its walls, and the upper and thickened portion (forming the neck), the canalis vaginalis—continuous with the peritoneal cavity above, and its communication with the tunica vaginalis below, only partially interrupted by the contraction of its walls at the spot before mentioned, viz., the lower stricture.

After the operation, the edges of the external wound was united by silver sutures, and a pad and bandage then applied.

*First Day after Operation.* He looked composed and easy, and complained only of slight pain in the abdomen, which he attributed to not being able to pass urine properly, and for which, in the evening of this day, a catheter had to be used. The abdomen was tense and tympanitic, but not tender, and moved in respiration, which was 24. He had had no vomiting since the operation; the bowels had been freely opened five or six times. Pulse 132; full and jerking. He had taken four soap and opium pills at intervals since the operation, and had slept a little.

*Second Day.* He was not so well. His countenance rather pinched and depressed, and his voice lower and less confident. He had had pain in the left iliac region, but this was now relieved after the application of a linseed poultice. The abdomen was tense and tympanitic as before, but not tender, and moved in respiration, which was 20, and not painful. The bowels had not been open since last note. He had taken, besides beef-tea and milk, an ounce of brandy, and twenty-five minims of laudanum. Pulse 144; small, compressible, and jerking.

*Third Day.* He was rather better in almost every respect, and he took, besides beef-tea and milk, four ounces of brandy, and soap and opium pills night and morning.

*Fourth Day.* He again became worse, suffering, however, from but little pain or tenderness in the abdomen; but he began now to vomit a greenish-yellow fluid, besides the small quantities of beef-tea, wine, and brandy, etc., which were given to him at intervals. Respiration was abdominal as well as thoracic, but increased in frequency (36). The bowels acted twice freely. The motions were tolerably healthy. Pulse 140; weak and jerking.

*Fifth and Sixth Days.* He became still worse; being only partially conscious now and then, though answering questions rationally. His face was pinched and dull, but he complained of but little pain in the abdomen, or elsewhere. The abdomen was moderately distended, and only slightly tender; it continued to move, though not very freely, in respiration, which increased in frequency to 40. The vomiting continued, and nothing could be retained on the stomach for more than a minute

or two. The bowels acted *eight* or *nine* times in those two days, very freely and loosely. The motions had a pale yellow colour. The pulse was frequent and weak. The wound had continued to look tolerably healthy, with only slight suppurating.

He died on the sixth day after the operation.

**POST MORTEM EXAMINATION.** Slight general and recent peritonitis was found in the intestines occupying the upper part of the peritoneal cavity; but there was evidence of much more intense and apparently older inflammation (by several days) in the cavity of the pelvis, and in the coils immediately continuous, as well as in contact with the portion of bowel which had been protruded during life. This portion, which proved to be the lowest portion of ileum immediately before its entrance into the cæcum, lay opposite the internal ring. That part of it which had been nipped by the second stricture had undergone a further change, rather of ulceration than of sloughing, by which a rent had been made large enough to admit the tip of the little finger; and through this opening feces had escaped into the abdominal cavity, though their diffusion had been to some extent prevented by the close adhesion of neighbouring coils, through the medium of thick layers of yellow lymph. Very little loss of substance had occurred; the edges of the rent being brought into nearly even apposition with no difficulty. Immediately around the opening, the coats of the bowel were dark, and at one spot thinned; but their consistence was tolerably firm. No alteration had apparently occurred in the small black spot noticed at the time of operation. In the last eighteen inches or two feet of the ileum, there were evidences of acute inflammation of all the coats of the intestine, which was dark, congested, and thickened; the almost black congestion extending through its whole thickness, and being very distinct on the mucous membrane of its interior. Beyond this part, the colour of the bowel changed abruptly into a much lighter one; and the general signs of inflammation became also much less marked as the upper part of the intestinal canal was approached.

In a clinical lecture on this case, Mr. Paget, after describing the condition of parts to which the term congenital hernia is applied, proceeded to speak of the different ways in which the communication which naturally exists in the later part of fetal life between the peritoneum and tunica vaginalis, is closed. This closure takes place usually from above downwards, by a gradual contraction of the canal, by which its walls are brought into apposition. But occasionally this process occurs only at both ends of the canal, while the intermediate part remains unobliterated; or there is a partial adhesion at different points in the course of the canal, by which the latter is converted into two or more sacs communicating more or less freely with each other. In such cases, the sacs may become filled with fluid, and then the condition known as hydrocele of the cord is produced. In many cases, again, the canal remains permanently open; or, as in the present case, there is an imperfect contraction of its walls at each extremity.

The frequency of hernia in early life is due to this unclosed state of the processus vaginalis; but it does not follow that a hernia should take place of necessity in all cases in which this patent condition of the canal exists.

Here was a patient thirty-one years old, who, so far as he himself or his mother knew, had had no hernia or other swelling until a few days before his admittance

into the hospital. Mr. Paget said that he had operated some time since on a man aged 58, who had had a hernia for only four months, and yet it was "congenital"; and he referred to another case of the same kind in an adult who was under the care of Mr. Lawrence.

We should be very cautious, Mr. Paget said, in promising the cure of congenital hernia occurring in early life. His usual treatment was to order a truss to be worn for five years; and, if no descent occurred in that time, to allow it to be left off. If, however, any descent should take place, he ordered the truss to be worn for four or five years more. But even if this plan has been carefully followed, the patient cannot be quite sure that he is cured. In the cases just related, no truss had been worn; but this was not the cause of the non-closure of the canal. In the case of a student who had congenital hernia in infancy, a truss was worn for five years; and, as no descent occurred in this time, he left it off. Fifteen years passed without any descent, and then the intestine again came down and was strangulated, requiring the administration of chloroform before it could be reduced.

Mr. Paget said he believed there were no dissections showing the effects of the pressure of a truss on the processus vaginalis in congenital hernia. It is generally said to produce adhesion of the walls by causing inflammation of their opposed surfaces; but it is more probable that it merely allows the natural changes of contraction and obliteration, which are not at all like those of adhesive inflammation, to proceed, uninterrupted by any hernial descent. The sooner, therefore, that this treatment—wearing a truss—is begun, the greater is the probability of success. The pressure need not be great; enough to prevent the descent of the hernia will be all that is required.

In the present case there was an unusual condition of the walls of the canal of the tunica vaginalis; they were thickened, corrugated, etc.; not like the ordinary condition in encysted hydrocele of the cord, which they might have been expected somewhat to resemble. There was also an unusual shape of the communication between the canal and the sac of the tunica vaginalis; and it was so completely closed by the piece of intestine which had descended, that the fluid, which had collected in the sac of the tunica vaginalis, was prevented from escaping into the canal, which contained none; and hence the unequal characters of hardness in the long neck of the sac and softness in the lower part of it.

The case served well to show the usual seat of stricture in congenital hernia; viz., in the mouth or neck of the sac. But, as in this patient, there may be also another lower down—at the junction of the canal with the sac of the tunica vaginalis. Mr. Paget remarked, that this was the second case he had operated on in which he found a stricture in the latter situation. In the operation itself there was nothing very worthy of remark; but after it, within a few hours, the patient, had five or six rapid actions of the bowels. This was almost always a bad sign; for it indicated a very morbid state of the intestines, and it disturbed what should be at rest. In this case it apparently added much to the causes of death. It was probably due to the quantity of

physic which the patient had taken previously to his admission into the hospital and before the discovery of the hernia.

In conclusion, Mr. Paget said that in many cases an operation for the relief of strangulated hernia, even when satisfactorily done, leaves the patient in a complicated state from the following conditions:—

1. The necessary effects of the strangulation.
2. Frequently continuance of a disease preceding the strangulation—colic, diarrhoea, dyspepsia, etc.
3. Very frequently the effects of accumulated physic.
4. The effects of chloroform and the operation.

Here, the *post mortem* examination showed the existence of enteritis as well as of peritonitis, but chiefly of perforation occurring late in the progress of the case; though, at the time of the operation, the vitality of the part pressed by the stricture did not seem to be materially impaired. But all these were attended with obscure and somewhat unusual symptoms, which it would be difficult to explain very satisfactorily.

## Reviews and Notices.

ON DISEASES OF THE CHEST, INCLUDING DISEASES OF THE HEART AND GREAT VESSELS: their Pathology, Physical Diagnosis, Symptoms, and Treatment. By HENRY WILLIAM FULLER, M.D. Cantab.; Fellow of the Royal College of Physicians; Physician to St. George's Hospital; etc. Pp. 703. London: 1862.

THE announcement of any contribution to medical literature by Dr. FULLER must by this time naturally carry with it the idea of something valuable; nor will those who may study the volume before us, be disappointed in their expectations of gaining instruction. Perhaps, however, this estimate will bear a slight qualification in respect to one important department of the book—we mean those parts in which the author speaks of physical examination, especially by means of the ear. So far as it is possible to describe the sound-signs of thoracic disease on paper, Dr. Fuller has done it well; and all credit is due to him for the plan which he has followed, and which is set forth in the following extract from his preface:—

“My object has been . . . to render attainable by men of ordinary capacities and ordinary opportunities a science which is indispensable to every medical practitioner. I have endeavoured to begin at the beginning, to assume nothing, and to explain every auscultatory sign by reference to the morbid condition, and consequent altered mechanism, in which each takes its origin. My wish has been to inculcate the necessity for regarding each physical sign, not as indicative of a certain disease, but rather as the natural consequence of a certain physical alteration in the tissues, the source and true interpretation of which must be determined by concomitant circumstances. I have endeavoured to use the simplest language, so as to obviate the formidable difficulty presented by the confused and varied phraseology made use of by many writers on the subject, to give a definite meaning to each term which is employed, and to present a classification of the various sounds which shall be intelligible even to a novice at auscultation.”

While we highly commend the objects which Dr.

Fuller sets forth in this extract, we must offer some criticism on the first sentence. We doubt greatly, indeed, whether it is possible to teach the sounds of the chest and their modifications by written description. The Horatian maxim,

“Segnius irritant animum demissa per aurem,  
Quàm quæ sunt oculis subjecta fidelibus,”

is reversed here. Sounds cannot be learned and understood unless they are heard by the learner. We can readily imagine a man having a perfect theoretical knowledge of sound, and of all the *minutiae* of music, and yet unable to distinguish one musical instrument from another, or even one note or one piece of music from another, unless his ears have also been trained. The student of chest-diseases must gain his knowledge of the sounds from actually hearing them, under the guidance of competent instructors. In this way alone he can learn them. He has not even the imperfect substitute for the object itself, which drawings, or paintings, or models, can afford in the description of things that may be seen.

As means of teaching the sounds, then, not Dr. Fuller's book alone, but all books on the same subject, are defective. But they have their value, in enabling the student and practitioner to arrange and coordinate his ideas of the sounds which he has heard, and to refer each to the condition producing it. In carrying out this object, Dr. Fuller has laboured well, and, it seems to us, with success. As has been already said, his aim is simplicity of description; he avoids the minute distinctions which have been drawn by some writers, at the same time that the terms which he uses are sufficiently explicit. Thus, in speaking of the sounds elicited by percussion, he first classifies them as clear toned and dull toned; full toned and shallow toned; high pitched and low pitched; and also in combinations, as clear and full toned (healthy pulmonary resonance); clear but shallow toned; dull but full toned; dull and shallow toned. Such terms as “tubular,” “tracheal,” “amphoric,” “cracked-pot,” etc., he objects to, especially when they imply a theory as to the origin of the sound.

In his descriptions of the several classes of the physical phenomena presented by the chest, Dr. Fuller has arranged the signs in tables, giving his nomenclature of the sounds, their synonyms, characters, mode of production, and seat, and the diseases with which they are usually associated. To any one who knows the sounds or is learning them, these tables, in connection with the more elaborate descriptions which precede them, will be useful.

We observe also, that in describing some of the diseases of the chest—*e.g.*, pleurisy, pneumonia, and bronchitis—Dr. Fuller arranges the symptoms and the physical signs of each stage in parallel columns; so as to show their connection in the most obvious manner short of actual demonstration.

A notice of Dr. Fuller's opinions on certain debated points may be interesting.

One of these points is ægophony. Dr. Fuller regards it as essentially bronchophony, to which is imparted a tremulous bleating character. The agency producing this character

“Must be one of two kinds; either some tenacious secretion vibrating in the bronchial tubes and producing an effect analogous to the vibrating tongue of reed-in-

struments, which possibly may be, though I somewhat doubt it, an occasional cause of ægophonic resonance over hepatised lungs; or, which I believe to be its source in cases of pleuritic effusion, the impulse of the vibrating and partly solidified lung against the costal pleura. . . . Under ordinary circumstances, solidified lung lies closely in contact with the costal pleura, and practically, for all purposes of vibration, may be considered as connected with it; consequently, unless some cause of jarring tremulous vibration exists within the lung itself, as in the instance of a vibrating piece of mucus in a bronchus, the vocal resonance will be purely bronchophonic and not ægophonic. But just at the surface of a pleuritic effusion there must be a point at which the lung is barely separated from the chest-walls, and in which the bronchophonic vibrations of the lung must lead to that light jarring impulse of the visceral against the costal pleura, which analogy proves conclusively to be a frequent cause of a peculiarly tremulous bleating sound—the sound which characterises ægophony.” (P. 108.)

Dr. Fuller believes that pleuritic effusion, slightly separating the two surfaces of the membranes, is the most common cause of ægophony—the conditions for bronchophony previously existing in the lung; and that this is its invariable source when the sound is well developed and persistent.

In speaking of paracentesis thoracis for the relief of pleuritic effusion, Dr. Fuller differs from those who lay great stress on the importance of the non-admission of air into the pleural cavity. The instruments devised for this purpose are, in his experience, ineffective; for he has found that so long as precautions were taken (by means of cannulae with valves and stop-cocks) to exclude air, but little fluid escaped; while, as soon as air was admitted, the liquid flowed freely. He does not believe the admission of air to be so dangerous as many think, in the stage when paracentesis is generally performed—when acute inflammatory action has subsided.

“It does not necessarily excite suppurative inflammation of the pleura. This has been proved in many cases in which serous fluid has been drawn off by the cannula without the subsequent occurrence of supuration. Again, the existence of air in the pleura is not found to interfere with the re-expansion of the lung in the cases now under discussion. The lung is already compressed by the fluid, and in most cases is slow in regaining its due expansion; and, as air is rapidly absorbed from the pleural cavity, its temporary admission in cases of paracentesis is, in this point of view, of little moment.” (P. 192.)

Regarding bloodletting in pneumonia, Dr. Fuller places no trust in conclusions either for or against the practice, derived from statistics which overlook various sources of error. He relies more on common sense and experience.

“Common sense points out that what is serviceable in one case will prove mischievous in another, under different conditions of age, sex, constitution, and the like; and experience not only endorses this view, but proves that under certain circumstances bloodletting is a palliative of extreme value. . . . Phlebotomy should not be resorted to, except when its employment is most clearly indicated; and even then it should be employed very cautiously. In my own practice at St. George's Hospital and elsewhere, I have had recourse to it in pneumonia three times only within the last four years; but I am satisfied, nevertheless, that in each of these cases it was the means of affording great relief, and that cases do occur from time to time in which its employment is absolutely necessary to the well-being of the patient.” (P. 235.)

We could go on noticing other points of interest; but we must bring this notice to an end, assuring our readers that while in this book Dr. Fuller exhibits great research and learning in regard to the theory of diseases of the lungs and heart, he at the same time puts forth the results of his experience in a manner calculated to be of practical value in matters therapeutic.

ON DISEASES OF THE SKIN. By ERASMUS WILSON, F.R.S. Fifth Edition. Pp. 784. London: 1863.

A book which has reached its fifth edition does not require much notice from the reviewer; and therefore Mr. WILSON'S classical work, with the emendations and additions which he tells us he has introduced, may be safely left to that professional judgment which, it appears, has hitherto given it high and merited approval. The preface to the present edition, however, contains remarks on the general pathology and classification of skin-diseases, which are of some interest in the present age of change and progress. Mr. Wilson tells that, when the first edition of this book appeared, twenty years ago, he constructed a physiological classification of cutaneous diseases; but that, being convinced that “a classification must be sought for that would carry with it the idea and principle on which our curative operations ought to be conducted”, he, in his fourth edition, arranged the skin-diseases in an etiological classification, which is followed in the present edition. This classification is, however, applied only to diseases affecting the general structure of the skin; which are divided into those arising from general causes; from special external causes; from special internal causes; from the syphilitic poison; and from animal poisons of unknown origin, giving rise to eruptive fevers. The physiological—or rather, anatomical—classification is still followed in regard to diseases of the special structures of the skin, which are classed as diseases of the vascular structure; of the nervous structure; of the papillary structure; of the pigmentary structure; of the sudoriparous organs; of the hair-follicles and hairs; and of the nail-follicles and nails.

The neuropathic theory of disease, which is gaining ground among practitioners of the present day, and which has been ably advocated in this JOURNAL by Dr. Handfield Jones, receives some support from Mr. Wilson. Accepting the views of neuropathists, he cannot yet abandon the time-honoured humoral theory, though its applicability to practice has been limited.

“Humoralism does not explain all the known phenomena of cutaneous disease; and for the simple reason that humoralism addresses itself only to the fluids of the body; and although it must be admitted that there can be no healthy solids without healthy fluids, yet, on the other hand, the nervous system plays so important a part in the health of the body, and in the health of the blood itself, that we are bound to recognise certain phenomena manifested by diseases of the skin as originating in the nervous system; as being, in fact, neuropathic phenomena. In the treatment of diseases of the skin, we must therefore chasten our humoral views with views drawn from a neurotic source—with dynamic views; and while we bestow our chief attention on the purification of the blood, we must at the same time comprehend the importance and secure the integrity of that governing influence, the nervous power.”

Arising naturally out of the recognition of the neuropathic nature of some skin-diseases, is the recognition of their purely local origin in many instances. This has been strongly impressed on Mr. Wilson by the writings of Professor Hebra of Vienna, as well as by several interviews during the last year with that distinguished dermatologist. Professor Hebra would treat by local means alone many diseases which "in this country, and with our humoral tendencies, we should be led to treat by constitutional as well as by local means". At what point between the two extremes the safe medium lies, has yet to be determined. Mr. Wilson believes we shall best learn by giving more attention than before to local treatment, while we do not give less to the constitutional.

**CHEMISTRY.** By WILLIAM THOMAS BRANDE, D.C.L., F.R.S.L. & E., of Her Majesty's Mint, Member of the Senate of the University of London, and Honorary Professor of Chemistry in the Royal Institution of Great Britain; and ALFRED SWAINE TAYLOR, M.D., F.R.S., Fellow of the Royal College of Physicians of London, and Professor of Chemistry and Medical Jurisprudence in Guy's Hospital. Pp. 892. London: 1863.

THIS book has been written for the express purposes of the student of chemistry by two masters of the science. If ever two writers could claim to know what the student requires in the way of a handbook to help him to a knowledge of the science, Drs. BRANDE and TAYLOR are the men. One of them, we are told, has been engaged in teaching chemistry these forty years; and more than a quarter of a century ago we ourselves had the good fortune to learn chemistry from the teachings of Dr. Taylor, in the lecture-room of Guy's Hospital. To criticise such a manual as this seems, therefore, a matter of superfluity.

Its authors have, doubtless, met successfully the two difficulties which try the powers of all writers on this subject; viz., the avoiding of profuseness—the telling of too much; and the avoiding of brevity and obscurity—the telling of too little. Specimens in this way are before us. At one end of the scale we find Mr. Galloway's "First Step", modestly containing ninety pages; and at the other end of it we find the translated "Handbook" of Gmelin, still unfinished, "filling at the present date fourteen octavo volumes, and covering nearly eight thousand pages"—*scriptus et in tergo, necdum finitus*. We can well imagine how difficult must be the art of condensing even into nine hundred closely printed pages all the details of modern chemistry, which the student expects to find ready to his hand; and yet what a fearful amount of necessary details is comprised in a knowledge of chemistry at the present day! Our authors, we are glad to see, have felt compassion for the medical student, who is called upon to obtain in about four years a knowledge or a smattering of at least eight sciences; and they have well said that "the efforts of those who contribute to the literature of these sciences should be directed to the elucidation of the most important facts and principles, omitting altogether those details which are either of a controversial nature, or are not yet established on a satisfactory basis." This is the spirit in which they have worked in the production of their volume. They have also done well in ex-

cluding from their pages those frightful formulæ, symbols, and mystical language, which are enough to strike awe and repulsion into the mind of the ingenuous student. It is, indeed, a great satisfaction to learn upon such authority that all such hazy technicalities and mysterious symbolism are not actually necessary for the acquirement of the modern facts of the science. "Our intention," Drs. Brande and Taylor say, "in the preparation of this volume, has been not to furnish a treatise on the science, but to provide the student and general reader with a plain introduction to the subject."

No space in the book has been sacrificed (as our authors deem it) to the introduction of woodcuts. They tell the students that, if they want to know about retorts, etc., "they will find in the illustrated catalogues of dealers in chemicals more correct representations of apparatus than those which are commonly met with in treatises on chemistry." By devoting the whole of the book to description, our authors have been enabled to condense into one thick and handy volume what might, we suppose, have been very readily expanded into two equally thick and inconvenient volumes.

The volume contains fifty-six chapters, in the first four of which are explained, Matter and its Properties; Crystallisation; Dimorphism; Isomorphism; Chemical Affinity; Solution; Electrolysis; Equivalent Weights and Measures; Nomenclature and Notation. The rest of the chapters are occupied with Metalloids, Metals, and Organic Chemistry. As a specimen of the authors' method of treating their subjects, we will give the reader their account of Dialysis.

"When a liquid will dissolve no more of a solid, it is said to be *saturated*; in other words, its adhesion or affinity for the solid is exhausted. It is a curious fact, however, that water which is saturated with one salt has still the property of dissolving a second and a third salt. Crystals of nitre may be thus freed from impurities, such as chloride of sodium, by washing them with a saturated solution of nitre. A saturated solution of a salt exerts a powerful attraction on water. If a saturated solution of sulphate of copper is enclosed in a funnel tube, secured at the larger end by bladder, and the tube is plunged in a vessel containing water, so that the liquids inside and outside are on a level, in the course of some hours it will be found that, although some of the copper-salt has passed out through the pores of the bladder, a much larger proportion of water has passed in. Solutions of common salt, sugar, and other substances, present this phenomenon, to which the term *endosmosis* (*ἔνδοσ* within and *ὠθεῖν* to push) has been applied. The diffusion of liquids, or their relative tendency to mix on contact, has been fully examined by Mr. Graham (*Quart. Jour. Chem. Soc.*, vol. iii, p. 60); and the effect of porous membranes in allowing liquids or dissolved solids to traverse them has also been made the subject of experiment by the same chemist. Mineral substances, such as arsenic, may thus be separated from organic matter. He has called this process *dialysis*. (*Proc. R. S.*, 1861, vol. xi, p. 243.)"

**BENEVOLENCE.** The following extraordinary act of benevolence has been reported by the chaplain to the Middlesex Hospital. A lady, being permitted to visit the wards on the 6th instant, went from bed to bed, and in the most quiet and gracious manner presented half-a-sovereign to almost every one of the patients as a New Year's gift, and as a thank-offering for her recovery from a dangerous illness. The number of patients so relieved amounted to nearly 300.

# British Medical Journal.

SATURDAY, JANUARY 24TH, 1863.

## A PRIVATE CHARGE MADE A PUBLIC SCANDAL.

IT is no slight matter to accuse a member of the medical profession of holding medical consultations with homœopaths. The profession has of late, thanks to the initiative action of the British Medical Association, taken an unmistakable stand upon this question. No man can now play fast and loose with medicine and with homœopathy, and do it with impunity. Every member of the profession feels and acknowledges that to be even suspected of such collusion is an evil not to be endured. A member of the profession a short time since, as some of our readers may remember, actually threatened a gentleman with an action-at-law for having asserted that he had met a homœopath in consultation! We need hardly say that we rejoice in this. The fact indicates a healthy and high tone of professional morality.

But if it be so serious a charge to allege against a member of the profession that he has met a homœopath in consultation, evident enough is it that such charge should not be lightly made—in fact, should not be made at all in public, unless the proofs are strong and undeniable. We have always acted on this view of the case, and have never permitted a charge of the kind to appear in these pages so long as it was mere matter of suspicion. Every honourably minded man must feel pained to have his name publicly connected with such a charge, even though perfectly free from the smallest inculpation in it. In our opinion (and, we think, in the opinion of every fair-dealing man), no one is justified, for the mere sake of creating a temporary sensation, or for feeding scandal-loving appetites, in publishing charges of this nature which he is not ready to support and justify from evidence which he holds in his hands. If the charge, privately inquired into, has been met by a clear and explicit answer, and if those who brought the charge are satisfied that they did so under an erroneous impression, nothing, in our opinion, but a love of creating scandal, could, under such circumstances, induce any one to drag the matter before the public. What other purpose, indeed, can such publication serve?

We make these remarks in reference to a charge lately brought against Dr. Burrows, that he has met a homœopath in consultation at Bedford. We ourselves received a letter on the subject; and having, on investigation, found that the charge was made under an utter misunderstanding of the facts of the

case; having communicated with Dr. Burrows, and at once received from him the most open and explicit statement, printed below; and finding not a shadow of blame could be justly laid to the charge of our respected and high-minded President in the matter,—we determined, if possible, to avoid all public allusion to it. We forwarded Dr. Burrows's letter to the gentleman who communicated with us, and received from him a satisfactory reply. We also accidentally had an opportunity of personally communicating with some of the leading members of the profession in Bedford; and from them we learnt that, in the first place, the belief that Dr. Burrows had knowingly met a homœopath in consultation was far from general in the town; and secondly, that the explanation contained in his letter (shown by us to them) was perfectly satisfactory. Moreover, we have seen a letter from one of the leading members of the profession there, expressing his indignation at the publication of the charge against Dr. Burrows.

Unless, therefore, the subject had been publicly brought forward by another journal (which states the charge, gives no evidence in proof, produces Dr. Burrows's letter, and yet either is or pretends to be so ignorant of the real merits of the case as to venture no opinion of its own on the subject), we should not have alluded to it in these pages. We trust our antecedents are guarantee enough to the profession that, had there been the slightest grounds for sustaining such a charge, we should have been the very last to let the matter subside into silence.

Having, then, had our attention called to the subject, we at once, as in duty bound, communicated with Dr. Burrows, and from him *immediately* received the following answer, of the date Jan. 9th.

*"To the Editor of the BRITISH MEDICAL JOURNAL.*

SIR,—Your communication has surprised and shocked me very much; and I think the gentleman who wrote to you would have acted in a better spirit if he had first written to me, and made me acquainted with some of the facts on which he supposed that I had consented to meet an homœopath in consultation. It is perfectly true that I was summoned to Bedford last week by electric telegraph, and which stated the case was urgent 'rheumatic fever and affection of the heart.' I went to Bedford as soon as practicable, and met in consultation the physician to the Bedford Infirmary and a gentleman in general practice, who was educated at St. Bartholomew's Hospital, and whom I had known for some years, who had many times sent patients to my house for advice and treatment.

"I found the case as described in the telegram, and that some syncope had occurred more than once. The treatment which had been pursued was, calomel and opium in repeated doses, a large blister over the sternum, and moderate quantities of wine. I prescribed the calomel in smaller doses with the same quantity of opium, a large linseed poultice over the chest, and

brandy instead of wine, and alkaline remedies. The urgency of the symptoms required my attendance on the patient two days afterwards, when I met the same gentleman, and I prescribed ether and ammonia at short intervals; also aromatic confection and tincture of opium to control some irritation of the bowels produced by the calomel. I wrote the prescriptions myself, affixed the signatures of the gentlemen in attendance as well as my own, and the medicines were prepared by the medical man in regular attendance. I saw the patient, at his own strong request, a third time, and prescribed remedies of the same kind.

"I think you and the whole profession will agree with me, that in the antecedents of the case, in the position of the medical attendants on the patient, in the character of the remedies which had been employed before my arrival and of those which were suggested by myself and assented to by the other medical attendants, there was nothing which could for one moment lead me to suspect that I was in consultation with homœopaths. I cannot but in charity suppose there must be some mistake, and that the gentleman who has written to you is misinformed. I cannot conceive why he should suspect me of forgetting my position and belying my principles, so far as to meet homœopaths in consultation. I never did such a thing, and, unless my principles and convictions should be completely changed, I never will do so.

"I am, etc.,

"GEORGE BURROWS.

"18, Cavendish Square, Jan. 9, 1863."

Such is the explicit answer instantly given by Dr. Burrows to the charge anonymously, as far as he was concerned, preferred against him. The opinions of Dr. Burrows on the subject of homœopathic consultations are well known, and have been often unhesitatingly expressed. Dr. Burrows, as we also well know, strongly sympathises with and cordially supports the views often expressed on this subject in these pages. In accepting the Presidency of this Association, he publicly accepted the position in reference to homœopathy maintained by the Association. Moreover, his whole career, and high standing and reputation give the distinctest *à priori* denial, with those who know him, to the truth of such a charge as applicable to him. For these reasons, as we have already said, to publish the charge, as it lay before us, would have been, in our view, simply the fomenting of a scandal.

But we must do Dr. Burrows full justice in the matter. He has not in the smallest way desired to escape any proper publicity. In our communication with him on the subject, he expressed but one opinion, that "he considered his interests and the interests of the profession were identical," and that whatever was judged best for the good of the profession was the course to be pursued in such a case. We are satisfied that the whole profession will gladly admit that Dr. Burrows has, from first to last, acted in this matter in accordance with the highest principles of professional honour; and we are satisfied that none of his medical brethren will more cordially

rejoice at his letter, and sympathise with him for any annoyance he has suffered, than those gentlemen who had imagined it possible, from the facts before them, that Dr. Burrows had knowingly consulted with a homœopath.

### OUR SUPPLY OF MEDICAL CHARITIES.

If it were possible, it would evidently be a most desirable thing that we should make use of any data we possess by which to form something like a reasonable estimate of the amount of hospital accommodation which is required for the people of this metropolis. We have already proposed the question, and we should like much to obtain some answer to it; viz., What is really the estimated number of beds required to meet the medical and surgical necessities of the poor in the neighbourhood of the late St. Thomas's Hospital? Did the supply of beds equal the demand before the removal of the hospital? Was the supply below the demand? or was it just the fit and proper supply for the emergency presenting? Now, if we are not much misinformed, it is a fact that Guy's Hospital, notwithstanding the departure from its immediate vicinity of its late nosocomial neighbour, has not had put upon it, nor has in any way suffered from, any severe strain upon its hospitable powers. Notwithstanding the departure of St. Thomas's Hospital, and the diminished number of beds now afforded by that hospital at the Surrey Gardens, Guy's Hospital is, as we hear, fully equal to all the demands made upon it. If this is an exact statement of the case, would it not be of much instruction for us to learn why the case stands thus? Is it the fact, for example, that in former days the supply of beds in St. Thomas's and Guy's was so large that patients were admitted as in- who are at other hospitals treated as out-patients? Is more discrimination now shown in the class of persons and the class of diseases admitted? Is it the fact that Guy's Hospital is really equal to all the ordinary emergencies of disease in its district? or is it even now more than equal to them? And, if so, of what value is the argument which demands the reinstatement of St. Thomas's Hospital on its former site?

Questions of this kind seem to us to be at this moment of the very highest importance. Is it or is it not possible for us to ascertain from hospital statistics something like an estimate of what are the real nosocomial wants of a given district? Like certain articles of commerce, does the supply of hospitals create and increase the demand for them? Are the daily begging petitions in the columns of the *Times*, wherein is detailed the lamentable semi-bankrupt condition of all our hospitals except the royal ones—are they real, actual indications of the demands and wants of sickness and misery? or is the poverty-smitten state of these institutions the

result of the eager demand created by an over generous supply? Seriously, we would ask our medical brethren this question: Is there no proper limit to medical charity? Is there no possible way of estimating what is the real amount of medical charity required for a given population? Will any man believe that a hospital confines itself to its proper business of doing the charitable to those who are worthy and proper objects of its charity, when he learns that, for instance, some forty thousand out-patients have received its medical attentions during one year? Of this we are thoroughly convinced: that it is high time our hospital system underwent a strict investigation. The fervent begging petitions of our medical charities are, we believe and hope, an indication that the charitable public begins to think there ought to be some limit assigned to gratuitous medicine. It is hardly credible that, in this land of bountiful giving, such screams for charitable succour to the miseries of sickness would require daily publication, if there were not doubts in the mind of the public as to the proper disposition of their charity. If the actual and *proper* wants of the metropolis in this particular were laid before the public, no one can doubt but that the want would be soon more than met.

### THE WEEK.

Six sites have been mentioned by the grand committee of St. Thomas's Hospital, in a report to the governors, for the new building. The committee think it desirable to rebuild the hospital in a position accessible to the labouring classes of South London, the question of erecting an auxiliary suburban hospital being left for future consideration. The sites are:—1. Bethlehem Hospital; extent, 11 acres; estimated cost, £160,000. As a new Bethlehem Hospital would have to be constructed, five years would probably elapse before St. Thomas's Hospital could be finished on this site. 2. Land belonging to the Fishmongers' Company, on the eastern side of the Walworth Road, about a quarter of a mile beyond the Elephant and Castle; probable extent (provided other adjoining premises are purchased), 15 acres; estimated cost, £104,000 or more. 3. Surrey Gardens, with adjoining premises; area, about 17 acres; estimated cost about £100,500. 4. A tract of open ground at the back of Newington Church. The interests on this ground are reported to be various and complicated, and difficult to be dealt with. 5. A piece of land known as Myatt's ground, close to the Camberwell station of the London, Chatham, and Dover Railway; area, 30 acres; estimated cost, £39,000. 6. A portion of the land to be reclaimed by the proposed southern embankment of the Thames, and the property between

it and the Palace New Road, immediately opposite the Houses of Parliament. The part to be reclaimed is about  $1\frac{1}{2}$  acre in extent; the remaining portion,  $5\frac{1}{2}$  acres; in all, 7 acres. On Tuesday last, a general court of the governors of the hospital was held, under the presidency of Alderman Sir John Musgrove, for the purpose of considering the report of the grand committee. The merits of the several sites were canvassed at some length; but the weight of opinion, so far as it could be collected, seemed to be in favour of that upon which Bethlehem Hospital now stands. It was felt, however, that the question is not yet sufficiently mature to enable the court to decide between conflicting claims; and ultimately, the reports of the surveyors were referred back to the committee, with a view to obtain more particulars and information, and to report thereon on a future day.

Two interesting points of law have been raised by an action tried a few days ago at Nisi Prius: 1. Can a physician, a *Member* of the London College of Physicians, make a legal claim for services rendered? And 2. Is the bye-law of the London College, which prevents *Fellows* of the College from recovering money due for services, a legal bye-law? That is to say: Can the College legally make a bye-law of such a nature, which shall apply to the *Fellows* only, and not include also the *Members*? Dr. Gibbon, a *Member* of the London College, brought an action to recover for medical services rendered by him. It was objected that his case was bad; and it was argued that,

"Previous to the passing of the Medical Act, the universal rule was that physicians were assumed to attend gratuitously, for which they expected an *honorarium*; they could not recover the amount of their charges for attendance unless there was a special contract. The Act of Parliament enacted that physicians registered under it might recover reasonable charges, subject to such by-laws as might be passed by the London College of Physicians. Now, the London College of Physicians had passed a by-law which directed that its *Fellows* should not recover, even if there were a contract. Mr. Baron Bramwell hereupon remarked—'You say that the Act of Parliament has merely put a further difficulty in the way of a physician's recovering the amount of his charges for attendance; I should think that the Act was drawn up by a person who was no lawyer.' On being told that the by-law of the College only referred to the *Fellows*, and not to the *members*, and therefore did not apply to the present case, he said—'Does not that give rise to a curious question, whether under the Act the College has a right to make a by-law referring to one portion of their body only. I am sure I don't see any great magic in the word 'physician,' which should distinguish him from the general practitioner, so far as to prevent him recovering the amount of his charges. The Act states that all reasonable charges are to be recovered, which could not relate to charges to be made under a contract, and therefore it must be supposed that the intention of the Act was that the physician was to recover the charges for his attendance like any other professional man. If the statute meant merely to say that if registered you shall have a title to sue in cases where you could otherwise sue, it would have merely said, 'You may sue,'

in place of saying, 'You may recover reasonable charges.' By the word 'reasonable' being used in the place of the word 'fixed' charges, one would think that the Act meant to take away the disability that physicians formerly laboured under. However, I think that there is sufficient difficulty to make it right to reserve the question, the difficulty of which is much increased by the manner in which the Act of Parliament is drawn up. Eventually, the jury returned a verdict for the plaintiff for the amount claimed, leave being reserved to the defendant to move the Court above as to the construction to be placed upon the Medical Act."

MR. PRESCOTT HEWETT, on taking the chair of President of the Pathological Society, announced that a general index of the Society's *Transactions* was in progress; and that he trusted, before his term of office expired, that the members of the society would be in possession of such a valuable key to the treasures contained in their published volumes.

MR. GRIFFIN requests us to state that he has received, through the editor of the *Lancet*, from A. Keppel Reed, Esq., Garrison and Civil Surgeon, Attock, India, £22:13:4, as a subscription towards the Puckett Fund, from the following subscribers:

Assistant-Surgeon Baillie, 10 rupees; Mrs. Blackall, Attock, 10 r.; Captain Blackall, 5 r.; Murree Church Offering Fund, 35 r.; Colonel Carleton, Royal Artillery, 5 r.; Major-General Sir S. Cotton, 10 r.; Mr. Dyer, Murree Brewery, 5 r.; Lieut. Drake, 32nd N.I., 5 r.; Captain Elliott, 94th Regiment, 16 r.; Mr. Finn, Public Works, 2 r.; Mrs. Green, Mean Meer, 5 r.; W. Green, Esq., Punjab Police, 5 r.; Captain A. D. C. Heyland, 10 r.; Lieut.-Colonel Kinderides, R.A., 16 r.; Captain Langmork, Barrack Master, 5 r.; Lieut. March, Sappers and Miners, 5 r.; M. M. R., 3 r.; Mrs. Morrison, 3 r.; Lieut. Morland, Murree, 5 r.; Col. Olpherts, Murree, 5 r.; Mr. Powell, Murree, 3 r.; J. B. C., 5 r.; Assistant-Surgeon A. K. Reed, 21 r.; Assistant-Surgeon J. B. Reade, 5 r.; Rev. Kilbee Stuart, Murree, 15 r.; Major Sandilands, Attock, 10 r.; Captain Urnstone, 5 r.; Captain Ware, 51st K.L.I., 5 r.; Jas. Wright, Esq., C.E., 10 r.; total rupees, 244.

Mr. Griffin wishes us further to state that the list is now closed; £1,074:8:10 having been received, and the handsome provision of £52 *per annum* made for the widow, the capital ultimately to be divided amongst the children.

It appears that, whilst the farmer in England is energetically active in destroying the small birds on his farm, the farmer of New Zealand is making every effort to obtain a supply of these small birds on his farm, for the purpose of destroying the insects which ravage his crops. We read:

"The Acclimatisation Society of New Zealand are doing all in their power to promote the introduction into this colony of English field-birds. Should their efforts prove successful, they will secure to these islands an incalculable amount of good by destroying the myriads of insects which now enjoy an undisturbed existence upon the growing crops of our farmers. The undermentioned amounts will be paid by the society upon the delivery in Auckland, in a healthy condition, of a cock and hen of the following birds: Blackcock or grouse, cock

and hen, £10:10; silver pheasants ditto, £5; nightingales ditto, £5; English partridge ditto, £1; cuckoos ditto, £3; missel thrush ditto, £2; common thrush ditto, £2; blackbirds ditto, £2; starlings ditto, £2; skylarks ditto, £2; rooks ditto, £2; crows ditto, £2; jays ditto, £1:10; robins ditto, £1:10; wrens ditto, £1:10; bullfinches ditto, £1; grey linnet ditto, 15s.; green linnet ditto, 15s.; sparrows ditto, 15s.; goldfinches ditto, 15s.; English quail ditto, £1. The society will also pay £5 for hares per couple, male and female; and £15 for red deer, male and female."

THE elevation of M. Velpeau to the Presidency of the French Academy of Sciences will remind the profession of Sir Benjamin Brodie's occupation of the chair of the Royal Society. "M. Velpeau," writes the French journalist, "is about to occupy the highest position which ambition can desire, President of the Academy of Sciences! Can there be any higher title? This eminent distinction is accorded to him for his works, for his long services, and for his well-occupied life. The Academy in its choice, has honoured itself, and at the same time the medical profession."

M. Philips has given to the Société Médicale des Hôpitaux the sum of 5000 *francs* for the foundation of a prize for the best works on "The Treatment and the Curability of Tubercular Meningitis."

The celebrated chemist Lehmann, of Jena, died suddenly of apoplexy the week before last.

The *Wiener Medic. Wochenschr.* says that Professor Langenbeck, of Berlin, was lately summoned by telegram to Brussels to perform lithotripsy on King Leopold; but the weak state of the patient prevented the operation, and M. Langenbeck returned to Berlin.

MM. Velpeau and Philipeaux have addressed a paper to the French Academy relating their experiments relative to the union of nerves of sensation with nerves of motion. Their experiments have succeeded. The branch, for example, of the fifth pair, which is distributed to the tongue, having been divided, was united to one of the divided branches of the hypoglossal nerve. Continuity was established between the two nerves. The results of this union have not yet been given.

A communication relative to table-turning was lately made to the French Academy.

At the Hôpital des Enfants, we are told, that during the month of December last there were five consecutive cases of cure in five consecutive cases of tracheotomy.

M. Rayer, we read, deposited on the bureau of the Academy of Medicine: 1. In the name of M. le Professeur Wm. Lawrence of St. Bartholomew's Hospital, a volume entitled, *Leçons de Chirurgie*; 2. In the name of Dr. Murchison, a volume on *Typhus and Typhoid Fever*.

M. Velpeau, late Vice-President, has been elected

President of the Academy of Sciences for the year 1863. During the past year the Academy has lost three of its titular members, MM. Biot, Sénarmont, and Gasparin, in whose places have been elected MM. Blanchard, Bonnet, and Pasteur. Of its foreign associates and foreign correspondents, it has lost, amongst others, Sir Benjamin Brodie and M. Bretonneau.

M. Larrey, on taking the President's chair at the Academy of Medicine, complained of the unsuitable position assigned to the Academy at the Tuileries presentations, and of the silence imposed on the President on these occasions, who was thus unable to lay before the Emperor the griefs of the company.

The French Academicians of Medicine have been of late engaged in tearing to rags the subject of drinking waters. They are making every scientific effort to learn what is the best sort—the most hygienic kind of water fitted for man's purposes; and in the meantime half Paris has no water supply at all.

Homœopathic doses of physic have always had, we supposed, certain promising qualities. They were, we were always led to believe, tasteless, and harmless, and neat, and elegant. But we now find that the infinitesimal sugar of milk and oyster-shell powders are no longer sufficiently efficacious. A series of new medicines has been offered to amateurs in this way. Their titles are taken from the work of a Dr. Hagers (1861), *Medicamenta Homœopathica et Isopathica*. By isopathic remedies, the author means the morbid products proper to combat the diseases which furnish them. The reader may judge of the character of these remedial agents from the following specimens of them: *Coryzium*, the mucus of coryza; *herculisium*, the foam from the lips of an epileptic; *leucorrhisium*, leucorrhœal discharge; *balanorrhisium*, the sebaceous matter of balanitis; *sudorisium pedum*, even; and *humanisium*, human excrements! Whether this learned man's treatise has or has not yet been introduced to the notice of his *confrères* in England we know not.

M. Velpeau inaugurated his functions as President of the Academy of Sciences by cutting short a painful and personal discussion between two astronomers, MM. Faye and Le Verrier. "It is always from the heavens," says the journalist, "that our disturbances come."

The Préfet of Milan has, by a late decree, forbidden the practice of medicine and surgery by any unlicensed individual. The increase of charlatanism, the decree sets forth, is a serious danger to the public health.

The Medico-Chirurgical Society of Paris has chosen M. Ségalas president for the current year.

## SIR BENJAMIN BRODIE, BART.

FULL of professional honours and well-stricken in years, this eminent surgeon and excellent man rests from his labours. Few have attained to such high distinction. Few have so well merited the position which he so long occupied. The unanimous accord of the medical profession and of the public had for many years placed him above rivalry. Successive sovereigns had conferred upon him the highest dignity awarded to the members of his profession—that of personal attendance on Royalty. His individual amiability confirmed what his genius accomplished. Our pride in him left no room for jealousy of his success. To trace the progress of Sir Benjamin Brodie would be to review the advance of scientific surgery for the last half-century. An experimental philosopher, who regarded the organism as materials for the exercise of life. An analytical inquirer, who traced the operations of life through the molecular constitution of matter. A practical anatomist, familiar with the intricate machinery of the body. A profound physiologist, who interpreted the book of Nature from the writing of her works. An operating surgeon, whose manual dexterity placed the mechanism of his art first amongst the sciences. A practical physician, whose treatment of disease reduced the philosophy of medicine to the noblest of arts. A great man, gifted with an order of intellect, which, in any age, would have accomplished mighty results, and which, in a period remarkable for the boldness and grandeur of its progress, worthily achieved for him a first position amongst the master-minds of the day. Such was Sir Benjamin Brodie. It is not for us to do more than honour his memory and emulate his example. It is ordained for each once to die. His was a placid termination to an honourable and a blameless life. In common with all we express our affectionate respect for the illustrious dead, and indulge our selfish sorrow at his departure from amongst us.

This is not the occasion to review Sir Benjamin Brodie's contributions to that special department of medical science to which this *Journal* has been more particularly directed. It is enough to say that all that he has written he has written well. While the sense of our professional bereavement is yet keen, we forbear from any more lengthened investigation of that brilliant career which our contemporaries have so well placed in detail before the profession. Sir Benjamin Brodie yet lives—lives in the present, and lives for time. His eulogy will ever be perpetuated where suffering succumbs to the treatment his profound perception bequeathed to those who follow him. His epitaph will not be erased from the hearts of any whose privilege it has been to know this great and good man. (*Medical Critic and Psychological Journal*, January 1863.)

## PROFESSIONAL PHOTOGRAPHS.

THE Council of the Medical and Chirurgical Society have determined to add to their valuable library, a collection of photographs of subjects having professional interest, to be mounted in suitable portfolios, and accompanied by descriptions of the cases or preparations thus illustrated. The Assistant-Librarian of the Society (53 Berners Street) will receive any contributions from members of the profession who can assist towards so valuable and interesting a collection.

## Association Intelligence.

### BRANCH MEETINGS TO BE HELD.

NAME OF BRANCH.	PLACE OF MEETING.	DATE.
NORTH WALES. [Ordinary.]	Dudley Arms Hotel, Rhyl.	Tuesday, Jan. 27, 1.22 P.M.

### NOTICE REGARDING NEW MEMBERS.

By desire of the Committee of Council, the General Secretary requests that the Local Secretaries will be good enough to forward to him the names of all New Members who join the Association through the Branches; as otherwise the JOURNAL cannot be sent to them.

PHILIP H. WILLIAMS, M.D., *General Secretary.*

Worcester, November 16th, 1862.

### NORTH WALES BRANCH.

AN ordinary meeting of the members of this Branch will be held on Tuesday, January 27, 1863, at 1.22 P.M., at the Dudley Arms Hotel, Rhyl.

Gentlemen having papers or cases to communicate, will please to give an early intimation of the same to the Secretary.

D. K. JONES, *Hon. Sec.*

Beaumaris, January 13th, 1863.

## Reports of Societies.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JANUARY 13TH, 1863.

B. G. BABINGTON, M.D., F.R.S., President, in the Chair.

ON THE WIRE COMPRESS: A SUBSTITUTE FOR THE LIGATURE. BY JOHN DIX, ESQ., HULL.

[Communicated by JOHN BIRKETT, F.R.C.S.]

THE wire compress—the subject of this paper—is a modification of the method of arresting hæmorrhage devised by Dr. Simpson of Edinburgh, and introduced by him about three years ago as a substitute for the ligature. The “acupressure,” as it is called, has been tested by but few surgeons of note; and in London, especially, it is almost unknown and ignored. Although probably a real improvement on the ligature, it undoubtedly labours under certain inherent disadvantages, most or all of which (it is believed) are obviated by the use of a fine wire of iron or of silver, instead of the steel needles of Dr. Simpson.

This idea was first promulgated in a paper on Acupressure published in the *Medical Times and Gazette* of June 2nd, 1860: and first put to the proof in a case of amputation of the finger, September 1860. In this operation two arteries were secured by wire, which was removed on the third day. The case did well: there was no bleeding, and very slight suppuration.

In the next case—Chopart's amputation, performed April 26th, 1861—five wires were applied on as many arteries: four of these were removed in forty-eight hours, and the other on the fourth day. It was found that the wire was easily applied, as easily withdrawn, and entirely effectual for the purpose it was intended to serve—namely, the arrest of the bleeding from the cut vessels. The patient, being the subject of constitutional syphilis, did badly. There was sloughing of the entire surface of the wound, and the flap was totally destroyed; notwithstanding which there was no hæmorrhage; but she died on the thirteenth day after the operation, of pyæmia.

In an amputation of the thigh, done September 21st, 1861, after Mr. Luke's method, there were seven bleeding arteries. Upon five of these the wire was used, and with the femoral artery the femoral vein was intentionally included; two very small branches were treated by torsion. This case did well. Seventy-two hours after the operation four of the “presse-artère” wires were withdrawn with perfect ease and without bleeding. The one on the femoral remained five days, when it, too, was removed without any difficulty and without a trace of blood. There was but little suppuration, and an excellent stump was the ultimate result.

These cases proved that this mode of securing arteries is practicable, efficient, safe, and manageable. It was also believed to possess a certain positive superiority over the ligature, as the following comparison showed.

A ligature in a wound impedes union and induces suppuration. Cure, by primary adhesion, of a large wound—as, for instance, an amputation—is an event of extreme rarity, and this because of the ligatures. A thread of silk is, in fact, a miniature seton, and the whole number required in an operation make up one of considerable size, and can scarcely fail to lead to the formation of pus. Again, the ligature of necessity excites ulceration of the artery upon which it is tied; it cannot in any other way be got rid of. This is another unhealthy process, antagonistic of repair. In applying a ligature, the end of the artery is drawn out from its sheath, by which its natural connexions are disturbed and its vasa vasorum broken up; its coats also are lacerated and bruised. The ligature remains for an indefinite time, long after it is useful or necessary, and it is not unfrequently pulled at by the dresser before it has become detached. Its knot, often deeply buried between the flaps, cannot be withdrawn without tearing through adhesions, or damaging the granulations. All these are serious obstacles to the healing process both in the stump and in the artery itself, and much protract the period of cure. Moreover, the following is an interesting and noteworthy formula: Pyæmia is the offspring of purulent secretion, of which the ligature is an efficient and probable cause. Bleeding arises solely from ulceration of an artery, of which again the *primum mobile* is the ligature.

From one and all of these objections to the ligature, the “wire compress” is almost or altogether free. Thus, in accordance with a well-known pathological law, *it*, being a metallic substance, is freely tolerated by the living body, and has little or no tendency to excite suppuration or irritation. Neither does it cause ulceration of the artery. This is positively affirmed from actual observation of its effect as witnessed in the sloughing stump before alluded to. It is applied without interference with the natural relations and vital connexions of the vessel. It is removed at any time, according to the will and judgment of the surgeon, without disturbance to the reparative action going on in the artery and in the rest of the wound, without futile premature attempts, and almost without pain to the patient. It is not liable to loose its hold, or to become detached too soon, as not unfrequently happens to a ligature applied upon a brittle or sloughing artery. Twigs of nerve accidentally included in the embrace of the wire are not injured and excited as by the tight strangulation of the ligature, and, if thought advisable, the veins are easily and safely occluded, along with the arteries.

Although this has been spoken of merely as a modification of acupressure, yet it is believed to be a decided and important improvement on “Simpson's skewers,” as the needles have been irreverently called, and which are fairly open to the following objections. When several of them are required, the stump resents, as it were, being thus pierced through and through in various directions. From the injury thus inflicted, and from the

obstruction to the capillary circulation caused by the pressure of the unyielding steel, arise much tension, œdematous swelling, and great pain; the pain, especially, has been found a very serious evil. Again, their projecting ends, and the puckering they cause in the substance of the flaps, interfere very much with that accurate adjustment of the cut surfaces and edges which so greatly aids the chances of union by adhesion.

The wire is free from all these shortcomings. It is thus applied. Take a piece of surgical wire six or eight inches long, and thread each end thereof upon a straight needle. Seize the bleeding mouth of the artery with forceps, and pass one of the aforesaid needles close on each side of the artery just mentioned, about a line above the points of the forceps, directly down through the substance of the flaps, so that they emerge at the cuticular surface, about half an inch distant from each other. Draw them both through together till the curve of the wire compresses the artery on the face of the flap. Now get rid of the needles by clipping through the wire close above their eyes, and also detach the artery-forceps. Place a piece of cork, cut for the occasion, upon the skin, between the points of exit of the wire, and over this twist the wire tighter and tighter until the bleeding is arrested. Lastly, cut off the superfluous wire. All which is done quicker than described. Two or more arteries lying near together may be embraced by one wire; and, as has been said, the veins may be included or excluded at will.

The wire should be either of silver, or, what is much cheaper and equally manageable, of the finest and softest passive iron. The generality of wire, as used for sutures, is too hard and stiff. The needles are about three inches in length, straight, and three-edged, with an eye adapted for carrying wire. Special care is necessary in threading the wire, that it is kept perfectly free from all twisting. The forceps are used, not to draw out the artery as when a ligature has to be applied (this, indeed, is to be particularly avoided), but merely as a guide to mark the exact position and course of the vessel. The cork is necessary to protect the skin from the pressure of the wire.

The withdrawal of the wire, which at first sight appears an insuperable difficulty, is perfectly simple and easy. It is thus effected. Clip the wire close to the edge of the piece of cork, and straighten out the curve it has formed, at its exit from the skin. Remove the cork, and apply instead the tip of one finger, with which press firmly upon the flap, making traction gently and gradually upon the other end of the wire. If this were roughly and hastily done, it might break up the adhesion which it is presumed has taken place between the surfaces of the flaps, and it is quite possible that a flexure in the wire might lacerate the artery in passing over it; but it is certain that none of these evils need happen with ordinary care and tact.

As to the period of withdrawal, further observations are desirable; but it has been clearly shown in numerous cases of acupressure, that for small vessels a few hours of compression are sufficient, and for the largest arteries a much less time than might be supposed. However, as a general rule, it is not desirable to disturb a wound in any way for from twenty-four to forty-eight hours, at the end of which time all wires commanding the secondary branches may be safely removed, and probably also from the large arteries; but, as a matter of prudence, it is well to keep a check upon such a one as the femoral for three or four days at least.

The descriptions hitherto given apply particularly to amputations; but the wire is equally applicable to many other operations.

In a postscript to this paper was related a case of excision of the testicle, in which it was used most satisfactorily upon the vessels of the cord. Two wires were required, and they were removed on the fourth day. Also

a case of excision of the breast, in which three wires were applied, and removed in twenty-four hours. The wound, which was six inches long, healed kindly and rapidly—almost without suppuration.

Suppose the femoral artery needs to be secured for popliteal aneurism. The wire would be passed under the artery by means of a tubular aneurism-needle made for the purpose, brought out through the integument at a convenient situation, and then twisted upon a cork in the usual way. This same artery, cut in amputation, is securely closed in three or four days by the action of metallic pressure; consequently, in three or four days the wire might be removed. Meanwhile, it has not caused suppuration, or impeded the union of the wound, which ought, therefore, by this time to be completely healed; and more important still, the artery is not cut through, as by the ligature, but its coats remain intact, and bleeding is impossible.

It will probably be found that the pedicle in ovariotomy may be conveniently dealt with by this method, the arteries being secured individually, and the entire stump also fixed to the abdominal wall by another wire. This idea has been already promulgated by Mr. Spencer Wells.

The paper was illustrated by models.

## OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, JANUARY 7TH, 1863.

W. TYLER SMITH, M.D., President, in the Chair.

After the ordinary meeting, the business of the annual meeting commenced.

The Report of the Auditors of the accounts of the Treasurer for the year ending December 31st, 1862, was then read, from which it appeared that the balance in the hands of the Treasurer was £204:9:2, and that during the year a sum of £400 had been invested in the funds in the names of the trustees of the Society. The balance-sheet read by the Secretary showed that the Society had received during the year £478:15 as subscriptions from fellows, and £48:9:3 as proceeds of the sale of the *Transactions* of the Society.

Dr. GREENHALGH, in moving the adoption of the Report of the Auditors, alluded to the satisfactory condition of the funds, and also to the fact that the sum received during the past year in subscriptions exceeded that of any previous year; the respective amounts received during the years 1859, '60, '61, and '62 being £336, £413, £445, and £478; while a total sum of 100 guineas had been paid into the Society's hands in respect to the proceeds of the first three volumes of the Society's *Transactions*. He also congratulated the Society on the promising condition of the library.

Dr. MEADOWS seconded the resolution, which was carried unanimously.

Dr. RICHARDS moved, and Mr. MITCHELL seconded the following resolution, which was carried by acclamation:—

"That the best thanks of the Society be and are hereby given to the President and officers of the Society for their services during the past year. That the best thanks of the Society be in an especial manner given to the retiring President, Dr. Tyler Smith, and to the retiring Honorary Secretary, Dr. Tanner: to Dr. Tyler Smith for the able and efficient manner in which he has presided over the meetings of the Society for the past two years; and to Dr. Tanner for his valuable and zealous services as Honorary Secretary from the commencement of the Society, four years ago, until the present time."

Dr. TYLER SMITH and Dr. TANNER respectively returned thanks.

The list of donations during the past year was read,

from which it appeared that 605 volumes had been presented to the Society by Sir Charles Locock, Bart., Dr. Clay of Manchester, and others.

*Officers.* The following gentlemen were elected officers of the Society for the year 1863:—

*Honorary President*—Sir Charles Locock, Bart., M.D.; *President*—H. Oldham, M.D. *Vice-Presidents*—J. Hall Davis, M.D.; R. Druitt, M.R.C.P.; W. Fergusson, Esq.; Robert Harley, Esq. (Hull); J. G. Swayne, M.D. (Bristol); and T. H. Tanner, M.D. *Treasurer*—R. Barnes, M.D. *Honorary Secretaries*—Graily Hewitt, M.D., and Braxton Hicks, M.D. *Other Members of Council*—H. Woodruffe Bailey, Esq. (Thetford); C. Clay, M.D. (Manchester); Wm. Fred. Cleveland, M.D.; C. Drage, M.D. (Hatfield); G. T. Gream, M.D.; R. Greenhalgh, M.D.; F. Seymour Haden, Esq.; G. Harley, M.D.; Isaac Harrison, Esq. (Reading); Henry James, Esq.; J. C. Langmore, M.B.; Alfred Meadows, M.D.; H. Madge, M.D.; Joseph T. Mitchell, Esq.; W. Tyler Smith, M.D.; F. Symonds, Esq. (Oxford); Alfred J. Tapson, M.D.; and J. G. Wilson, M.D. (Glasgow).

*Annual Address.* The first point dwelt upon in the address was the financial and numerical prosperity of the Society. The success of the volume of *Transactions* for 1862 was then briefly referred to. The additions made to the library during the year, the unique value which would attach to a large collection of purely obstetrical works, and the need which existed for appointing a librarian, and making some arrangement which should render the books accessible to the fellows, were next alluded to. The loss of fellows by death during the year was stated to be unusually large, including the names of Dr. Metcalfe Basington, Dr. Waller, Mr. Jessop (of Cheltenham), Mr. Smith (of Crawley), Mr. Rowland (of Wrexham), and others. The trials which had occurred during the year, in which persons practising midwifery were accused of malpraxis, were commented on, and especial notice was taken of the case of Mr. Robinson, convicted of manslaughter at the Central Criminal Court. It was shown that in many of these cases the charge of malpraxis arose out of the attendance of midwives in the first instance; and the anomaly that midwives, without any special training or qualification, are allowed to attend in cases often involving the question of life or death, was commented on. The progress of ovariotomy during the year, and its evident connexion with obstetric practice, were noticed. The recent discussion respecting the genealogy of the Chamberlens and the discovery of the forceps, was alluded to, and reasons were adduced for giving the merit to Mr. Peter Chamberlen, surgeon-accoucheur of the City of London, and the first of the family of whom we have any record. The address was concluded by the retiring President thanking the Society for the kind support which he had received during his tenure of office.

**AN ABSTAINER FROM MEATS AND ALCOHOL.** At a discussion which lately took place in Dublin, Mr. J. Haughton, who had himself lived in health for eighteen years without animal food or intoxicating drink, protested against the high feeding in prisons, ascribed the greater part of the crime of the country to intemperance, and protested in the strongest terms against capital punishment.

**CAUSE OF SAID PASHA'S DEATH.** It is now known that Said Pasha died of a cancerous affection of the rectum. M. Ricord, who had already attended him, and whom he had consulted during his last visit to Paris, had declared that he would die before he was a year older. His surgeons in ordinary had advised an operation, to which he had at last agreed; and M. Nélaton, who had been summoned to Egypt, was on the point of leaving Paris for that purpose when the news of the viceroy's death was received.

## Medical News.

**ROYAL COLLEGE OF SURGEONS.** The following gentlemen passed their primary examinations in Anatomy and Physiology, at meetings of the Court of Examiners, on January 13th, 14th, and 15th; and, when eligible, will be admitted to the pass examination.

**UNIVERSITY OF ST. ANDREW'S.** List of gentlemen on whom the degree of Doctor of Medicine was conferred, on December 31st, 1862:—

Anderson, John, M.R.C.S., L.A.C., Grantham
Allan, Patrick M., L.R.C.S.Ed., Arbroath
Bail, John J., Dublin
Ballard, William W., M.R.C.S., L.A.C., Tunbridge
Banks, Alfred J. H., M.R.C.S., L.A.C., Stafford
Barker, Edward R., M.R.C.S., L.A.C., Denbigh
Barnes, Thomas H., M.R.C.S., L.A.C., Suffolk
Barrett, Barnabas, M.R.C.S., L.A.C., Liverpool
Barrie, John T., L.F.P.S.Glasg., Newarthill, Lanark
Barwise, Joseph, L.A.C., Wigan, Lancashire
Beattie, Henry, M.R.C.S., L.A.C., Waltham Abbey
Beehy, Walter Thomas, London
Belcher, Joseph S., M.R.C.S., L.A.C., London
Blennerhassett, Rowland, L.R.C.S.I., L.C.P.E., co. Kerry, Ireland
Bowen, Josiah A., L.F.P.S.Glasg., Bretherton, Lancashire
Bramley, William S., M.R.C.S., L.A.C., St. John, Wakefield
Bright, John M., M.R.C.S., L.A.C., Forest Hill, Kent
Brown, Augustus, M.R.C.S., L.A.C., Islington
Brunwell, John R., M.R.C.S., L.A.C., Burnley
Bury, Edward C., M.R.C.S., L.A.C., Wisbeach
Candy, John, M.R.C.S., L.A.C., Alstonefield, near Ashbourne
Cannell, John, Peel, Isle of Man
Carrick, George L., Edinburgh
Cleghorn, James, Caithness
Creed, Thomas, M.R.C.S., L.A.C., Greenwich
Cresswell, Nathaniel E., M.R.C.S., L.A.C., Canterbury
Crompton, Samuel, M.R.C.S., L.A.C., Manchester
Curgiven, William G., Plymouth
Davies, David, M.R.C.S., L.A.C., London
Douglas, George, M.R.C.S., L.A.C., Gateshead-on-Tyne
Dowson, Edward, M.R.C.S., London
Ellerton, John, M.R.C.S., L.A.C., Wakefield, Yorkshire
Evers, Charles, M.R.C.S., L.A.C., London
Ewing, James, L.R.C.P.Ed., L.F.P.S.Glasg., New Lanark
Fawcus, Henry R., M.R.C.S., L.A.C., S. Charlton, Northumberland
Fegan, Richard, L.R.C.S.I., L.K.Q.P., Belfast
Ferguson, Alex. J., L.F.P.S.Glasg., Perth
Fernie, Edward, M.R.C.S., L.A.C., Macclesfield
Frame, John, L.F.P.S.Glasg., Glasgow
Frankish, John D., Guy's Hospital
Fulham, John, L.R.C.S.I., L.A.C., Drogheda
Furner, Charles, M.R.C.S., L.A.C., Brighton
George, Frederic, M.R.C.S., Cotterham, Surrey
George, Hugh, M.R.C.S., L.A.C., Revesby, Lincolnshire
Goddard, Richard W., M.R.C.S., L.A.C., London
Granshaw, James H., M.R.C.S., L.A.C., Gravesend
Greene, Michael, L.R.C.S.Ed., L.A.C., Ennis, co. Clare
Griffiths, Francis P., M.R.C.S., L.A.C., Sheffield

Griffith, Griffith H., M.R.C.S., L.A.C., L.R.C.P.Ed. by ex, Folkestone, Kent.  
 Griffith, James, M.R.C.S., L.A.C., Smarden, Kent.  
 Grove, John, M.R.C.S., L.A.C., London.  
 Gwyn, Samuel T., M.R.C.S., L.A.C., Whitechurch, Salop.  
 Harris, Abraham, L.R.C.P.Ed. by ex, M.R.C.S., L.A.C., Camborne, Cornwall.  
 Harris, Walter, M.R.C.S., London.  
 Hodgkinson, Edward Rodolph, L.A.C., Umhalloch, India.  
 Hopton, Abney C., M.R.C.S., Loudon.  
 Hughes, Ebenezer, L.F.P.S.Glasg., Liverpool.  
 Hulme, James D., M.R.C.S., L.A.C., Wigton.  
 Irvine, John W., L.R.C.S.Ed., L.A.C., Lancaster.  
 Jackson, Thomas, M.R.C.S., L.A.C., Scarborough.  
 James, Alfred, M.R.C.S., L.A.C., Forest Hill, Kent.  
 Johnson, James M., L.F.P.S.Glasg., Liverpool.  
 Jones, John E., M.R.C.S., L.A.C., Dolgelly, North Wales.  
 Keogh, Edward A., Dublin.  
 Lambert, Wm. O., L.F.P.S.Glasg., L.R.C.P.Lond., Sunderland.  
 Lawlor, Jeremiah, L.F.P.S.Glasg., Queestown.  
 Lees, Joseph, L.A.C., London.  
 Levey, John, M.R.C.S.Ed., L.M.  
 Lloyd, Edwin, M.R.C.S., L.A.C., Workop, Notts.  
 McDiarmid, Albert, M.R.C.S., L.A.C., Rochester, Kent.  
 Macdonogh, George V., L.R.C.S.I., Sunderland.  
 Macgown, John, L.F.P.S.Glasg., Millport.  
 McKenna, Arthur, L.R.C.S.Edin., H.M.S. *Hogue*.  
 Mackenzie, Wm. J., M.R.C.S., L.R.C.P., Greenwich.  
 Macintyre, Duncan, L.R.C.S.Ed., Fort William.  
 Marshall, John M., L.R.C.S.Ed., Edinburgh.  
 Mason, Thomas E.  
 Mayon, George, M.R.C.S., L.A.C., Newport, Monmouthshire.  
 Mayer, John, M.R.C.S., L.A.C., Macclesfield.  
 Miles, Edwin J., M.R.C.S., L.A.C., Gillingham, Dorset.  
 Mills, Thomas, M.R.C.S., Tipton, Staffordshire.  
 Mills, Wm. P., M.R.C.S., L.A.C., L.R.C.P.Lond., Ipswich.  
 Miller, John, L.F.P.S.Glasg., Glasgow.  
 Morrison, Peter, L.F.P.S.Glasg., Glasgow.  
 Moss, Edward L., L.R.C.S.I., L.M., Dublin.  
 Mulholland, Patrick, L.F.P.S.Glasg., Glasgow.  
 Murdoch, William, M.R.C.S., London.  
 Murray, Henry A., L.A.C., Evenwood, Durham.  
 Nell, George M., M.R.C.S., L.M.  
 Nelson, George D., M.R.C.S., L.A.C., Bridlington Quay.  
 Owen, John, M.R.C.S., L.A.C., Bromyard, Hereford.  
 Paterson, Robert, L.F.P.S.Glasg., Galston, Ayrshire.  
 Pullin, Thomas, M.R.C.S., L.A.C., Sidmouth, Devon.  
 Ransom, Robert, F.R.C.S., L.A.C., L.M., Cambridge.  
 Rawlins, William P., M.R.C.S., L.A.C., Kentish Town.  
 Reed, George, M.R.C.S., L.A.C., London.  
 Reed, Samuel C., L.R.C.P.Ed., M.R.C.S., L.A.C., London.  
 Reid, James B., L.F.P.S.Glasg., Ayrshire.  
 Rice, William, L.C.P.E., L.F.P.S.Glasg., Glasgow.  
 Ring, John, L.A.C., 1st ex. M.D., Kettering, Northamptonshire.  
 Roberts, John, M.R.C.S., L.A.C., Talaron, North Wales.  
 Rushton, John L., M.R.C.S., Macclesfield.  
 Samuels, Arthur, M.R.C.S., L.A.C., Liverpool.  
 Sandford, Polliott J., M.R.C.S., L.A.C., Drayton.  
 Scott, David, L.F.P.S.Glasg., Dunoon.  
 Sealy, George J., M.R.C.S., L.A.C., Maidstone, Kent.  
 Selwood, Henry C., M.R.C.S., Birkenhead.  
 Simons, Joseph A., M.R.C.S., L.A.C., Sussex.  
 Skae, Frederick, Edinburgh.  
 Smart, Francis W., L.R.C.S.I., Lie. K. & Q. Coll., Kilworth, Cork.  
 Smith, Andrew F., Treadmouth.  
 Smith, James A., L.F.P.S.Glasg., Glasgow.  
 Smith, John, M.R.C.S., L.A.C., Chatham.  
 Smith, Robert C., L.F.P.S.Glasg., Manchester.  
 Spicer, Robert H. S., L.R.C.P.Ed., M.R.C.S., North Molton.  
 Spry, George F., M.R.C.S., L.A.C., Army.  
 Staples, Joseph H. P., M.R.C.S., London.  
 Steel, Richard J. P., M.R.C.S., L.R.C.P.Ed., L.A.C., Blaenavon.  
 Steele, James, L.R.C.S.E., Lanarkshire.  
 Taylor, John W., New Malton, Yorkshire.  
 Teare, Thomas M., M.R.C.S., Ramsey, Isle of Man.  
 Telford, Samuel, L.R.C.S.I., Dublin.  
 Tessier, William H. C., L.A.C., Dublin.  
 Thomas, Richard R. G., L.R.C.P.Ed., L.M., Hartland, Devon.  
 Thompson, Robert Farren, L.R.C.S., L.A.C., Jarrow, Durham.  
 Trotter, Alexander, L.F.P.S.Glasg., Blyth, Northumberland.  
 Trotter, Charles H., M.R.C.S., L.A.C., Sydney.  
 Tyte, Edward C., M.R.C.S., L.A.C., Harrow.  
 Usher, Thomas S., M.R.C.S., L.A.C., Hull.  
 Waddington, E., L.R.C.P., L.R.C.P.Ed., L.R.C.S., Wakefield.  
 Waghorn, Frederick, M.R.C.S., London.  
 Ward, John, Glossop, near Manchester.  
 Warder, Alfred William, M.R.C.S., L.A.C., Ottery, Devon.  
 Warrington, Francis Wm., M.R.C.S., L.A.C., Congleton.  
 Watson, John, M.R.C.S., Manchester.  
 Webster, Joseph, M.R.C.S., L.R.C.P.Ed., Golcar, Huddersfield.  
 Weir, Archibald, F.R.C.S.Ed., Malvern.  
 Whipple, John H. C., Plymouth.  
 Wilson, James, M.R.C.S., L.A.C., Lancashire.  
 Wilson, Thomas, M.R.C.S., Lancashire.  
 Wise, Wm. C., M.R.C.S., L.A.C., Plumstead, Kent.  
 Wood, James, L.R.C.P.Ed., L.R.C.S., Kirkby Overblows.  
 Wood, William P., M.R.C.S., L.R.C.P., L.A.C., Rochdale.

Woodman, Frederick, L.R.C.P.Lond., M.R.C.S., Isleworth.  
 Wrangham, John D., M.R.C.S., L.A.C., Wragby, York.  
 Young, Henry J., M.R.C.S., L.A.C., Bath.

#### APOTHECARIES' HALL. On January 15th, the following Licentiates were admitted:—

Elliot, George Stokoe, Southwell, Notts.  
 Leeds, Edward, Stretford, near Manchester.  
 Parker, Benjamin Whitehead, Farrington, near Preston.  
 Reynolds, John, Truro, Cornwall.  
 Selwood, Henry Corpe, The Hospital, Birkenhead.  
 Yarrow, George Eugene, No. 8, Central Street, E.C.

At the same Court, the following passed the first examination:—

Coombs, Carey Pearce, St. Mary's Hospital.

#### APPOINTMENTS.

BELL, Joseph, M.D., appointed Assistant-Surgeon to the Edinburgh Eye Infirmary.  
 FITZGIBBON, Patrick, L.R.Q.C.P.I., appointed Medical Officer to the Clonmel Constabulary, in the room of the late J. W. Dowsley, M.D.  
 PALFREY, James, M.D., elected Physician to the Surrey Dispensary, in the room of G. Whitley, M.D.  
 SPANTON, William D., Esq., appointed Assistant House-Surgeon to the Sheffield Infirmary, in the room of A. E. H. Trotter, Esq.  
 WRIGHT, F. W., Esq., elected Resident Surgeon to the Birmingham and Midland Counties Lying-in Hospital, in the room of T. H. Hughes, M.D.

#### ARMY.

GALLWEY, Surgeon-Major M. B., Royal Artillery, to be Staff-Surgeon-Major, *vice* F. L. Fitzgerald.

To be Staff-Assistant-Surgeons:—

MILLAR, Assistant-Surgeon W., 76th Foot, *vice* W. R. Kerans.

#### ROYAL NAVY.

KEOWN, Thomas H., Esq., Surgeon, to the *Dauntless*.  
 MANSFIELD, Pierre, M.D., Assistant-Surgeon, to the *Caradoc*.  
 PRATT, Alfred J., Esq., Assistant-Surgeon, to the *Triton*.  
 RODGERS, Maxwell, M.D., Assistant-Surgeon, to Plymouth Hospital.  
 BROWNE, Thomas, Esq. } Acting-Assistant-Surgeons, to the  
 CARLETON, William, Esq. } *Victory*, for Haslar  
 FLETCHER, William B., Esq. } Hospital.  
 MANNING, N., M.D. }  
 STEVENS, William, Esq. }  
 CLARKE, John G., Esq. } Acting-Assistant-Surgeons, to the  
 HAINES, Frederick A. P., M.D. } *Royal Adelaide*, for  
 LAW, E., M.D. } Plymouth Hospital.  
 MACDERMOT, William L., Esq. }  
 SHIELD, John, Esq. }

#### MILITIA.

GOMPERTZ, W. F. L., Esq., to be Surgeon 6th Royal Lancashire Militia.

#### VOLUNTEERS. (A.V.—Artillery Volunteers; R.V.—Rifle Volunteers):—

BUTTERFIELD, H. H., Esq., Surgeon, to be Ensign 2nd Brecknockshire R.V.

To be Honorary Assistant-Surgeon:—

HOLMAN, C., M.D., 5th Surrey R.V.

#### BIRTH.

\*BRETT. On January 15th, at Watford, Herts, the wife of Alfred T. Brett, M.D., of a son.

#### DEATHS.

ARMSTRONG. At Peckham, on January 13, aged 2, Charlotte J., eldest daughter of Henry Armstrong, M.D.  
 DAVIS. On January 15, Mary, wife of George Davis, M.D., Dublin.  
 GARDNER. Roger, G. C., Esq., Surgeon, at St. Leonard's-on-Sea, aged 50, on January 17.  
 HEWLETT. On January 9, at St. Leonard's-on-Sea, the Rev. Alfred S. Hewlett, eldest son of \*Thomas Hewlett, Esq., of Harrow.  
 LADD. On January 20, at 9, Holland Place, Kennington Park, aged 18 months, Mary Ada, youngest daughter of Theodore E. Ladd, M.D.  
 STUCKEY, Henry, Esq., Surgeon, at 50, Wellclose Square, aged 28, on January 12.  
 WARDER. On January 13, at Ottery St. Mary, Devon, Alicia, wife of Alfred Warder, M.D.  
 WEBBER. On January 14, at 20, Connaught Square, aged 7, Mary F., daughter of Charles Webber, Esq., Surgeon.  
 WOOLCOMBE. On January 17, at Wooton Rectory, Northamptonshire, aged 72, Anne Elford, widow of William Woolcombe, M.D., of Plymouth.

**HUNTERIAN ORATION.** On February 14th prox. this biennial oration will be delivered by George Gulliver, Esq., in the theatre of the Royal College of Surgeons.

**LONGEVITY.** The obituary of the *Times* of the 21st inst. records the decease of persons who had attained the following advanced ages; viz., 92, 90, 82, 82, 80, 78, 78, 76, 74, 72, 72, 72, and 70 years respectively.

**THE MILK-COMPOSITION DISPUTE.** The interesting point in the matter is this: that the milk taken from the cow in the evening is richer than that which is obtained in the morning.

**DR. W. T. GAIRDNER**, who lately left Edinburgh to fill the office of Professor of Practice of Medicine in the Glasgow University, has been appointed Medical Officer of Health for that city.

**HEALTH OF MANCHESTER.** Notwithstanding the late dreaded rumours of coming fever, we learn with pleasure, that Manchester was never freer from fever than it is at the present moment.

**THE LINCOLNSHIRE POISONING CASES.** Gamer and his wife have been committed on two charges of wilful murder by arsenic-poisoning. Dr. Taylor showed that death resulted from arsenic; or at least found arsenic in the viscera.

**THE MILITARY SCHOOL OF ST. CYR** has been disbanded in consequence of the presence of typhus fever. Four of the scholars have fallen victims to the epidemic, and sixty are confined to their beds, many of them in a most critical state.

**MEDICAL SURVEYOR OF NUISANCES.** The Town Council of Leeds has been memorialised to appoint a medical man Surveyor of Nuisances. The increase and extent of impurities in the town has led to the demand of the services of such an officer.

**THE WELL KNOWN STATUE OF KING EDWARD VI.** which once stood in the centre of one of the quadrangles of the late St. Thomas's Hospital, has been removed to the present abode of the hospital. So also has the statue of Sir Robert Clayton.

**THE ACCIDENT TO THE PRINCESS ALICE.** Mr. Grove, the young medical student who so opportunely assisted Her Royal Highness the Princess of Hesse, when she was thrown from her carriage in the Isle of Wight a few weeks since, has been presented with a valuable gold pin and a set of shirt studs.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.** Professor Huxley, F.R.S., will commence his course of lectures on Comparative Anatomy, in the theatre of the College, on Tuesday, February 17th, at 4 o'clock, when he will deliver an inaugural lecture on the Skeleton of a *Glyptodon* recently presented to the museum of the Royal College of Surgeons by Senor Don Maximo Terro, the son-in-law of the celebrated General Rosas, who is living in retirement at Southampton. Mr. Waterhouse Hawkins, so well known in connexion with the restoration of certain extinct animals at the Crystal Palace, has been engaged for a considerable time past in making a perfect skeleton of this rare animal, from the innumerable fragments presented to the College by the above named liberal Spaniard. The introductory lecture will be followed by six lectures on the Classification, and on the Characters of the Principal Groups, of the Animal Kingdom; after which Professor Huxley will deliver twelve lectures on the Structure and Development of the Vertebrate Skeleton.

**THE UNIVERSITY OF ST. ANDREW'S AND ITS DEGREE.** During December last, 379 candidates presented themselves for the degree of M.D., of which number 336 passed, and 43 were rejected; of the former there were 32 without any qualification; all the others, possessed one, two, and three qualifications. The amount of fees

at £26:5 each arising from those who were *capped*, amounted to £8820; and if to this sum be added the four guineas forfeited by each of the 43 rejected candidates, making together £180:12, and added to the larger sum it gives a total of £9000:12. The government stamp of £10 on each diploma produces £3360. In addition to the 43 rejected on their examination, a great number withdrew without completing their work, and others without even commencing it, deterred from so doing by their antecedents being too well known by the University authorities; to whom great credit is due for their surveillance exercised on this the last occasion of such a rush, as in future the degree cannot be conferred without residence, except in the case of a few old practitioners, and then by a fee of fifty guineas instead of twenty-five guineas. (*Dublin Med. Press.*)

**A HOSPITAL PHYSICIAN'S AFTERNOON.**—The staff of the great hospitals is utterly insufficient to allow of their performing themselves the work allotted to them. . . . We discover every now and then a conscientious physician, who tries to do his work. We once calculated this work up in a particular instance. At half-past six in the evening the Esculapian bee was putting on his overcoat to return home; he had taken his seat in a wooden-bottomed chair at 1 p.m. For five and a half hours he had sat there, ringing his bell, calling out "Come in," examining his patients, and writing prescriptions, without a break. In the course of that period he had counted 4,480 strokes of the heart, listened to 86 chests, looked at 190 tongues, asked 1,120 questions, written 336 separate recipes, 11 certificates for clubs, 3 certificates of deaths, and brief notes in the hospital books of 29 new patients, giving their age, sex, occupation, duration of illness, residence, and disease. Altogether he had given advice *gratis* to 224 people, and remarked that he fell short of his usual number. Shall we describe the man at the end of his day's work? He was so pale that he might have played Ghost to Hamlet in broad sun-light. He was a little deaf on one side from the frequent use of the stethoscope; one of his fingers was sore from percussing; his eyes were wearied; his back ached intensely; his head was heavy, and his voice was hoarse and tremulous. He had a misgiving that at the close of his work he had written a prescription for one patient on another patient's letter, and was dreadfully put out to find that, right or wrong, the patients had gone off with their medicines. As he passed out of the hospital nine persons whom he had never seen in his life waited to ask him privately his solemn opinion as to cases some of which had not been before him for weeks, and of which he had no more recollection than of Adam. His face of white despair conveyed to the anxious listeners meanings of which he had not the remotest conception. When he got away from them all there were still three long miles yawning between himself and his dinner. (*Social Science Review.*)

**ON PAIN AND ANÆSTHETICS.** Dr. Valentine Mott, in an essay, advances the following propositions:—1. To prevent pain is humane; 2. Pain is useless to the pained; 3. Pain is positively injurious to the pained. Passing from the discussion of these propositions, the author considers the various narcotics used to assuage pain, and finally the use of anæsthetics. It will interest the profession to learn that the author prefers chloroform to ether. The rules which he gives for the exhibition of anæsthetics are excellent, and cannot be too carefully heeded. He concludes as follows:—"For such reasons then as have been recounted, I desire to direct the attention of the surgeons of the Army and Navy to the advantages which would accrue from a more extended use of anæsthetics in naval and military practice. I am satisfied that if, in these operations, the pain were more generally prevented, many lives would be saved which are now lost from the shock to the nervous system, and

thus in all severe cases, the prospect of recovery is better, and the subsequent inflammation is milder, when an anæsthetic has been used. To this conclusion I have not come hastily. Of so much import have I always regarded the prevention of the pain of operations, and so desirable, if it could be practically effected, that ten years before the introduction of anæsthetic vapour I listened patiently and attentively to the claims of animal magnetism to this power to produce insensibility; but found, and I may say with unalloyed regret, that when fairly brought to the test, its most ardent friends were compelled to admit its utter inefficiency, and even since the invention of anæsthetic inhalation, I have carefully tested the power of other agents, such as nitrous oxide, to produce insensibility to pain, but still consider none of them deserving of mention when compared with chloroform or ether. In conclusion, perhaps I may say, that these observations and reflections have been made during the intervals taken from a business still pressing, at a time of life when most men desire repose. They are given to the cause of American nationality, and may claim to be at least an old surgeon's offering on the altar of his country. The flag of our Union, the glorious stars and stripes, has repeatedly protected me in foreign lands beneath its broad folds, and if what I have written here shall be in any measure successful in preventing the sufferings and prolonging the lives of that noble army who are now serving under my country's banner, I shall receive my reward."

#### OPERATION DAYS AT THE HOSPITALS.

MONDAY.....Royal Free, 2 P.M.—Metropolitan Free, 2 P.M.—St. Mark's for Fistula and other Diseases of the Rectum, 1.15 P.M.—Samaritan, 2.30 P.M.—Lock, Clinical Demonstration and Operations, 1 P.M.

TUESDAY. .... Guy's, 1½ P.M.—Westminster, 2 P.M.

WEDNESDAY... St. Mary's, 1 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.

THURSDAY.... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—London, 1.30 P.M.—Great Northern, 2 P.M.—London Surgical Home, 2 P.M.—Royal Orthopædic, 2 P.M.

FRIDAY..... Westminster Ophthalmic, 1.30 P.M.

SATURDAY.... St. Thomas's, 1 P.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.

#### MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY. Medical Society of London, 8.30 P.M. Mr. W. C. Calthrop, "Spontaneous Closure of the Axillary Artery after Division (by a Gun-shot Wound), with final recovery of the Patient."—Royal Geographical.—Entomological (Anniversary).

TUESDAY. Royal Medical and Chirurgical Society, 8.30 P.M. Dr. Buchanan (of Glasgow), "On a White Fibro-Serous Discharge from the Thigh"; Dr. J. A. Marston, "On Syphilis as a Constitutional Disease."—Zoological.

WEDNESDAY. Society of Arts.

THURSDAY. Royal.—Antiquarian.

SATURDAY. Royal Institution.

#### POPULATION STATISTICS AND METEOROLOGY OF LONDON—JANUARY 17, 1863.

[From the Registrar-General's Report.]

Births. Deaths.

During week.....	{ Boys.. 984 }	1931	1477
	{ Girls.. 947 }		
Average of corresponding weeks 1853-62 .....		1934	1475

Barometer:  
Highest (Th.) 30.256; lowest (Sun.) 29.667; mean, 29.965.

Thermometer:  
Highest in sun—extremes (Th.) 60 degs.; (Sun.) 42 degs.  
In shade—highest (Th.) 46.8 degs.; lowest (Mon.) 27.7 degs.  
Mean—38.1 degrees; difference from mean of 43 yrs.+2.5 degs.  
Range—during week, 19.1 degrees; mean daily, 8.1 degrees.

Mean direction of wind, N.E.—Rain in inches, 0.74.

#### TO CORRESPONDENTS.

\*.\* All letters and communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen St., Lincoln's Inn Fields, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

DR. PHILBRICK'S CASE.—We regret to say that it is quite true that an action has been commenced against Dr. Philbrick by the husband of the woman whose death was the subject of the Coroner's Inquest at Leamington, to which we some few weeks ago called especial attention. It is manifest enough to us, that the man has not the slightest shadow of a chance of obtaining a verdict. We have no hesitation in saying, that the medical reasonings upon which was founded the allegation of Dr. Philbrick being in some way responsible for the woman's death, would fall to pieces at once in a Court of Justice. Nevertheless, if the action is brought, Dr. Philbrick will, under any circumstances, be sorely tried in purse as well as in temper. We are, therefore, glad to hear, that already he has received letters of sympathy and promises of pecuniary support from medical friends. We shall keep our readers apprised of the case; and, should the action go into a Court of Justice, shall again bring the facts of it prominently forward, in order to call upon the profession at large and the Association to support a gentleman—one of their own corps—who has, in our opinion, been most cruelly used, and especially by members of his own fraternity.

QUALIFICATIONS FOR DRUGGISTS' ASSISTANTS.—W. O. E. sends us the following advertisement from the *Times*:—

"CHEMISTS' ASSISTANTS.—Wanted, a competent Assistant, of good appearance and address, accustomed to first-class business, not under 24 years of age. Apply, stating age, height, and salary, Mr. Amos, Canterbury."

He remarks upon it:—Can it be that the druggist has an artistic eye, and requires a certain æsthetic conformity between the bottles, counter, and shelves, and the height and form of the dispenser? Does this picturesque aptitude for photographic effects add to the efficacy of the drugs and chemicals? or is it simply a homage to the lust of the eye? If stature is so important an element in the qualification of the retail chemist, it is but fair that a standard height should be declared in the prospectus of the Pharmaceutical Society, in order that all King John's "five foot men" should be thus warned to avoid a painful disappointment.

J. K.—Under the Pauper Lunacy Amendment Act, the following is the qualification of medical officers:—

"The term physician, surgeon, or apothecary, wherever used in the Lunacy Acts, shall mean a person registered under 'The Medical Act', passed in the session holden in the twenty-first and twenty-second years of the reign of her present Majesty, chap. 90."

F. T.—Our attention has been called to the following in a bankruptcy account lately published. It certainly is worthy of attention, and for this reason: that so many members of our profession have been unwarily led into many great difficulties in the same way. We fear that the mischief occurs more frequently than is generally supposed. Naturally enough, the sufferers, under such circumstances, do not care to have their misfortunes blazed about. This is the statement referred to:—

"Of the liabilities, £9,000 are in connection with the State Fire Office, of which bankrupt was the medical officer. He allowed his name to be put down for 3,000 shares, on the understanding that the allotment was to be nominal; but the company now being in course of winding-up, he was called upon for £3,000."

THE REPORTED DECAPITATION BY HANGING.—The account of the execution did not escape us. The incident occurred in the backwoods in Western Canada; and, as we all know, strange things have come from the woods of America—the famous puccoon, for example; and, more lately, a cure for another incurable disease—viz., for small-pox. We do not deny the fact, that a man's head might, in the act of hanging, be separated from his body by the jerk resulting from "plenty of rope"; but we must have better evidence before we believe it. It seems to us, that any rope which would be used for the purpose, would give way before the neck of the man would.

A CORRESPONDENT inquires if we can give him any information respecting the "noble charity" at No. 1, Red Lion Square, referred to in the *Holborn Journal* in the following terms:—

"Last week, a correspondent drew the attention of our readers to one of those noble charities with which our neighbourhood abounds; viz., the Infirmary for Diseases of the Leg, Red Lion Square. Though not strictly a local charity, our district nevertheless greatly benefits by its presence amongst us. Up to the year 1857, there was no institution established for the special treatment of a malady which so frequently afflicts the working classes, as that of disease of the leg. It was in that year that Mr. Thomas Westlake, the eminent surgeon, opened the hospital in our district; and up to the present time, the expense of maintaining this establishment, including the payment of rent, has been mainly borne by the founder. The committee of the institution have considered it unjust that Mr. Westlake should continue to bear the burden any longer, and have made an appeal to the public to take a share of it upon their own shoulders. To this, we have no doubt there will be an adequate response. An institution whose beneficial results have been so appreciated, that there have been four hundred applicants weekly, and one thousand cures of an almost incurable disease effected, will, we are persuaded, not be permitted to fail for want of funds."

[We were unaware of the existence of this noble charity. We find, on reference to the *Directory*, that 1, Red Lion Square, is the address of T. H. Westlake, Esq. We suppose, therefore, that there must be some mistake on the subject. EDITOR.]

MR. S. E. SMITH.—We have received a printed missile, entitled "Annual Report from the Case-Book of S. E. Smith, Esq., M.R.C.S.L., Cambridge House, Bristol." The Report consists of four lines; and informs us that Mr. Smith has cured 506, and has under treatment 403 patients of various ages. The rest of this cheaply got up document consists of extracts from various papers—*The London Medical Review*, *The Bristol Gazette*, *Bristol Mirror*, *Bristol Mercury*, *Daily Post*, and so forth; all, of course, to the effect that the aforesaid Mr. Smith is a man of surprising ability, and has performed "successful," "most interesting," "important" operations. What surprises us is, that there would appear to be some person who is envious of Mr. Smith's success; for at the end of his paper we read:—

"To prevent disappointment and imposition, Mr. Smith begs to state that he is not, nor has he ever been, professionally connected with any person whatever, and can only be consulted at his Chambers, Cambridge House, 22, College Green, Bristol, between the hours of eleven to three o'clock daily (Sundays excepted)."

We sincerely, however, trust that Mr. Smith is in error in supposing that any other member of the profession has really attempted to rob him of this fame and practice of his.

### SUBSCRIPTIONS.

THE following Laws of the Association will be strictly enforced:—

15. The subscription to the Association shall be One Guinea annually; and each member on paying his subscription shall be entitled to receive the publications of the Association of the current year. The subscriptions shall date from the 1st of January in each year, and shall be considered as due unless notice of withdrawal be given in writing to the Secretary on or before the 25th of December previous. If any member's subscription remain unpaid twelve months after it shall have become due, the publications of the Society shall be withheld from such member until his arrears be paid.

16. The name of no member shall remain on the books of the Association, whose arrears extend over three years; but the omission of the name from the list of members shall not be deemed, either in honour or equity, to relieve any member from his liability for the subscriptions due for the period during which he has availed himself of the privileges of membership.

PHILIP H. WILLIAMS, M.D., *General Secretary*.

Worcester, January 1863.

COMMUNICATIONS have been received from:—Dr. WILLIAM BUDD; Dr. P. M. LATHAM; Mr. ASHBY G. OSBORN; Mr. JAMES PAGET; Mr. C. F. BROWN; Dr. KIDD; Mr. JOSEPH HINTON; VON RURE; THE HONORARY SECRETARY OF THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY; Dr. HYDE SALTER; THE REGISTRAR OF THE MEDICAL SOCIETY OF LONDON; L.R.C.P.Ed.; Dr. SAMUEL WILKS; Dr. JOHN LYLE; Dr. J. B. NEVINS; Dr. JONATHAN TOOGOOD; Mr. THOMAS HORNEY; Dr. A. T. BRETT; Mr. PRESCOTT HEWITT; Dr. T. J. WALKER; Mr. H. G. WRIGHT; Mr. RICHARD GRIFFIN; Dr. GRAILY HEWITT; Dr. RENSHAW; Dr. WILLIAM ROBERTS; Δ; and Dr. BEALE.

### ADVERTISEMENTS.

**Wanted immediately, a Situation as DISPENSER to a Surgeon.** Can Visit and Attend Midwifery occasionally, if required.—Address Jno. HERWORTH, Surgeon, Croft's Bank, Patricroft, Manchester.

### Williams & Son's Pure Glycerine

SOAP, analysed by Dr. Hofmann, F.R.S., and Professor Redwood, Ph.D., strongly recommended by many eminent Members of the Medical Profession, and favourably noticed by the following Medical Journals.

*The British Medical Journal.*  
*The Lancet.*  
*The Medical Times and Gazette*  
*The Medical Circular.*  
*The Edinburgh Medical Journal.*  
*The Dublin Hospital Gazette.*

It is suited to all cases of delicate skin (whether arising from disease or otherwise), and is admirably adapted for nursery use. May be had of all respectable Chemists, Perfumers, etc.

SOAP WORKS, CLERKENWELL, LONDON, E.C.

FIRST-CLASS SILVER MEDAL. PARIS, 1855.

### S. Nye & Co.'s Small Mincer for the DINNER TABLE,

for those who cannot properly masticate, and who, in order to preserve health, should have their food thoroughly minced. Price 30s.—TESTIMONIAL: "I have had one of your Mincers for the Dinner-table in use for some time, and find it everything that can be wished. I recommend it to all who suffer from indigestion. T. SAUNDERS, Norfolk Villas, Bayswater."

LARGER MACHINES for Public Institutions, Lunatic Asylums, Hospitals, Schools and other establishments, effectually and quickly mincing all kinds of meat and vegetables, for soups, etc., forced and potted meats, and a variety of dishes; also for making sausages, cutting, mixing, and forcing into the skins at the same time. Price 21s., 30s., 42s., 63s., and £7 7.

Also MILLS on an improved construction for Coffee, Spice, etc. etc. Depot and Manufactory, 79, Wardour Street, London, W.

### Twinberrow's Patent

DOUBLE-ACTION RESERVOIR INJECTION APPARATUS is the most SIMPLE and PERFECT yet produced. The Piston, which so frequently gets out of order, is not introduced.

Twinberrow's Patent Double-Action SYPHON SYRINGE, with ADDITIONAL PIPES FOR ALL PURPOSES, possesses great advantages over other Syringes of a like description, having an UNINTERRUPTED STREAM, and consequently discharging DOUBLE THE QUANTITY OF FLUID IN HALF THE USUAL TIME and with MUCH LESS EXERTION.

#### TESTIMONIALS.

"TWINBERROW'S 'DOUBLE-ACTION' (Syphon) SYRINGE is the most generally useful Instrument of the kind with which I am acquainted. For the more ordinary purposes it is especially well fitted, being COMPACT, PORTABLE, and NOT LIABLE TO GET OUT OF ORDER. By a very simple arrangement the Instrument may be rendered available as an EYE DOUCHE, an EYE DOUCHE, an EAR SYRINGE, and for WASHING OUT THE BLADDER. For these purposes it is peculiarly well adapted, being continuous in its action.—JOHN ERICHSEN, Professor of Surgery at University College, and Surgeon to the Hospital."

"I have seen and made use of your DOUBLE-ACTION SYRINGE, and think very highly of it.—WM. FERGUSSON, Professor of Surgery at King's College, and Surgeon to the Hospital."

### Twinberrow's Patent Eye Douche.

(Testimonials from the First Oculists.)

By the action of the Eye Douche in common use, the stream is intermittent, consequently causing in some instances irritation; whereas, by employing the PATENT DOUCHE this objection is completely obviated, the fluid being projected in a continuous, gentle, soft shower.

TWINBERROW, Dispensing Chemist, Sole Patentee, 2, Edwards Street, Portman Square, London.

# Clinical Lectures

DELIVERED AT

CHARING CROSS HOSPITAL.

BY

HYDE SALTER, M.D., F.R.S.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS; LECTURER ON  
PHYSIOLOGY AND PATHOLOGY AT CHARING CROSS  
HOSPITAL MEDICAL SCHOOL; AND ASSISTANT-  
PHYSICIAN TO THE HOSPITAL.

## LECTURE V.—ON THE STETHOSCOPE.

*Principal Uses of the Stethoscope.—Rules for its Construction: 1, as to Material; 2, Length, Thickness, etc.; 3, Shape, etc., of Extremities—Practical Hints for its Manipulation—Method of Applying—Choice of Whereabouts to apply—Determining Limits of Sound—Ausculting Females and Children.*

GENTLEMEN,—You have made a request to me that I would give you a lecture on the stethoscope. To that request I accede with very great pleasure; partly because I think I can on that subject give you some valuable practical hints; and partly because I think there is no subject on which I could discourse to you, having wider or more important practical bearings, or on which we shall have more frequent occasion to fall back in the prosecution of our clinical studies.

The progression of a science is a *per saltum* progression; at one time making vast strides, at another remaining almost stationary. Or it may be compared to the course of a river—its bulk increased by sudden increments; flowing on for many miles without any augmentation of its stream, and then receiving an accession to its waters that doubles its volume. Thus, in the histories of sciences, times now and then occur, when a flood of light is poured upon them from some new source; or when some master mind arises and deciphers the hieroglyphics in which much that was before unknown was written; or when some happy accident suggests a new principle, or the new application of an old one; or when some new instrument, or aid to investigation, subjects to examination and analysis what before was beyond the ken of our senses. The laws of mathematics are brought to bear upon the movements of the heavenly bodies, and suddenly the physics of the universe become an affair of *plus* and *minus*, of roots and powers, of equations and logarithms. Or an Aristotle arises, and the science of Logic leaps, like Minerva, full grown, into existence. Or the motion of the lid of a tea-kettle suggests the idea of the steam-engine. Or the refraction of light by a convex lens serves to analyse the milky way into innumerable suns, or show teeming nations in a drop of water. Such instruments as the telescope, the microscope, and such like, may be said to be the representative instruments of the sciences they elucidate, for the advanced condition of those sciences, to which the instruments have brought them, is indissolubly connected with their discovery and employment. Such a representative instrument is the stethoscope. It is the representative instrument of the science of physical diagnosis.

But we must beware of exaggerating its powers and results; we must beware of that common error that affects the non-professional world, and even, to some extent, a portion of the professional world as well—that there is some mystery about it, that it is an instrument that *makes* sound; and we shall best assist it in its work by assigning to it its true place, and regarding it as a mere *aid* to auscultation—a medium, and not a power—a convenience, and not a necessity.

The principal value and advantages of the stethoscope appear to me to be the following:—

1. In the way of decency, cleanliness, and convenience.

To *decency* the use of the stethoscope contributes by obviating the necessity for that full exposure of the breast and the application of the bare ear to it, which, in the case of young females, would, through the association of shame with that which is sexual, and the sexual purpose of the mammary gland, amount to immodesty. How the use of the stethoscope would contribute to *cleanliness* on the part of the auscultator, I need not remind those who are familiar with the out-patient, and even the in-patient practice of our hospitals. The foul and sordid condition in which the sick members of “the great unwashed” present themselves to us is such as to render it not only intolerable, but often really almost impossible, to touch them. The stethoscope saves us from absolute contact, and, over and above, gives us the advantage of eight inches, or so, of distance. The employment of the stethoscope contributes to the *convenience* of auscultation by obviating the necessity of stooping so much over the patient, by rendering it unnecessary for him to come so near the edge of the bed, by making us in a great degree independent of the patient’s position, and by enabling us to listen to certain parts that the unaided ear could hardly reach, as the axilla, the supra- and sub-clavicular spaces in thin people, and the hollow sternum in some exceptionally formed chests.

2. The stethoscope enables us to circumscribe and localise the sounds that we hear. In proportion to the smallness of the chest-end of the instrument we are able to tell the precise seat of the greatest intensity of sound. If we work towards the sound and then from it—right and left, up and down—we can soon put our finger on the exact spot, and say “there it is”; and we can determine that spot with the greatest certainty—within a quarter of an inch. With the bare ear we cannot possibly do this; not only because the pinna is so large, and therefore gives such ill-defined information as to locality, but because when the head is applied to the chest the sounds are conducted to the internal ear by the bones of the cranium, so that the sound may be very well heard when the ear is not over the part at all. And not only can we by the use of the stethoscope tell precisely where the sound is, but whether it is circumscribed or extended, whether it covers a large or small space. By working the stethoscope round and round, and gradually contracting the circle, we can ascertain its area, and thus learn whether the morbid condition giving rise to it is distributed or strictly localised.

3. By removing the auscultator’s head from the patient’s body, the stethoscope often clears away fallacious crepitating or rubbing sounds produced by intervening hair, the friction of the patient’s clothes

etc. I have often lost a sound very closely representing pneumonic crepitation on substituting the stethoscope for the direct application of the ear to the chest.

4. By modifying and exaggerating the sounds heard, the stethoscope sometimes elicits characteristics and differences, and even the *existence* of certain auscultatory phenomena, that otherwise might escape detection. This advantage especially applies to certain exceptional forms of stethoscopes, and is not an unqualified advantage, because it implies an alteration as well as an exaggeration of the natural sound.

5. Lastly, shall I enumerate among the uses of the stethoscope that it tends to increase the faith of the patient? It implies that the doctor possesses a means of information not in the possession of the bystander. Not long ago I was amused by hearing a lady, and a not unintelligent lady, gently intimate to one of the most distinguished of living auscultators, who having carefully employed immediate auscultation was pronouncing his opinion on the case, "But you have not used the stethoscope?" implying, as far as her politeness would permit her, that auscultation without the use of that mysterious instrument was to her a thing of nought. Anything that increases our patient's confidence is of value; the strict adoption of the advice given often depends upon it.

I have just given you five kinds of reasons for the usefulness and value of the stethoscope. And now let me express an opinion that may seem in direct contradiction to all I have said; namely, that you will often find the naked ear much better. If I were condemned either never again to use the stethoscope, or never again to apply my bare ear to the chest—to give up the one or the other—I would give up the stethoscope. I have oftener found that I have got more certain and reliable information—that my appreciation of a doubtful sound has been more exact, that a half-heard sound has come into clear existence—by substituting the ear for the stethoscope than the stethoscope for the ear. For all the reasons I have mentioned the stethoscope is not only a valuable, it is an invaluable instrument; and its loss to auscultation would be irreparable. Nevertheless, my opinion is, on the whole, such as I have stated it. My advice, however, is, "Employ both means." By doing so you will correct errors on either side, and clear away the fallacies both of the mediate and intermediate method; and rare indeed will be the case in which you will not find their united testimony give you a more certain and reliable information than either of them alone. As a rule, the front of the chest most requires the stethoscope, while the back, convex and broad and free from *impedimenta*, presents the greatest facilities for the application of the ear.

It is not my purpose in the present lecture to give you the history of the instrument, or to settle the relative claims of Hippocrates, Hook, Bayle, or Laennec, to having given to the world the idea of auscultation; or to expound to you the acoustic principles upon which the stethoscope is constructed. My purpose is a very simple one and a very practical one—to enable you to do two things; first, to choose your stethoscope, and then to use it. I shall, therefore, divide my observations under the two following heads:—

a. Rules for the construction and choice of a stethoscope.

b. Practical hints for its manipulation.

And first, with regard to the principles upon which the stethoscope should be constructed, and the qualities which a good stethoscope ought to possess.

There are three principal circumstances that affect the quality of a stethoscope:—

1. Material.

2. Length and thickness.

3. Size and shape of extremities.

1. *Material.* What a stethoscope essentially is, is an instrument which will render audible at a distance from the chest the vibrations of which the thoracic parietes are the seat. What we want to know in using it is, what is going on inside a patient's chest, and the source that we look to for information is the sound or sounds that the healthy or diseased thoracic viscera generate. These sounds are heard, perfectly natural and unmodified, at the surface of the chest; the best stethoscope, therefore, and one that will give the most truthful information, will be that which delivers at its proximal end (*i.e.*, that which is applied to the ear) the sound that the most exactly corresponds with that which it receives at its distal end from the patient's chest-wall; in other words, that stethoscope will be the best, mediate auscultation with which will the most exactly correspond, in the sounds it furnishes, with immediate auscultation. We have, therefore, in this closeness of correspondence, a certain standard of the relative excellence of different stethoscopes.

The material that I believe the best fulfils these conditions, that gives, on the one hand, the smallest amount of loss of sound, and, on the other, the least perversion of sound, is that of which Laennec himself first recognised the value—some porous wood. What is the principle of this? I do not believe it has anything to do, as is often suggested, with the homogeneity of porous wood and lung—with wood being spongy and lung spongy—and a consequent similarity of the vibrating qualities of wood and lung; because we know, in the first place, that the vibrating qualities of healthy spongy lung are almost *nil*, while those of wood are excellent; and, in the second, that the vibrations that the stethoscope receives are not those of the lung, but of the chest-wall. I believe it has to do simply with wood being a good conductor and corroborator of all vibrations; that it depends on the same property in wood which makes it a good substance for fiddles, and for the walls of concert-rooms and speaking-halls.\* Cedar is the wood in general use, and there cannot be a better. Deal is cheaper, and equally beautiful when polished. I always use a deal stethoscope. The denser the wood the more does it modify the sound that it transmits, by its own inherent vibrations; the sound that we hear through an ebony stethoscope, for instance, has a peculiar tone about it, widely dif-

\* The principle on which wood conducts the vibrations that it receives, pure and unmodified, without the superaddition of any tone of its own and without echo, is much the same, I think, as that on which snow reflects pure white light without image. Each crystal of snow reflects, just as each cell of the porous wood vibrates; but the reflection is broken, and the multitudinous reflections give neither an image nor colour, but simple white light; so, each cell of wood being highly vibratile, and no two vibrating in unison, the aggregate vibration is neutral, and becomes conduction pure and simple, just as the white light of snow is reflection pure and simple.

ferent from that which we should hear from listening to the same sound with the bare ear.

A stethoscope should be made of one piece of wood, turned out of the solid block. The breaking of continuity involved by having it made of several parts, so as to take to pieces, must necessarily impair the perfection of its conducting power. Still more important is it that it should be of one material, and not part ivory and part cedar, as one often sees. There is no end to the absurdities of construction in this respect that stethoscopes exhibit. In some, the ear piece is ivory, and made to screw on and off; the shaft is cut in two in the middle, and each half furnished with an ivory end, the one to screw into the other; the chest-end is covered with an ivory cap, to screw on and off, and in its recesses is contained a little perforated cone of cedar, furnished with a small brass tube projecting some short distance up the centre of the stethoscope. Could anything be less likely to be a good conductor than such a heterogeneous and piecemeal concern? Some stethoscopes break up into as many pieces as a Chinese puzzle, and require as much ingenuity to put them together again. If a striking and compendious illustration were required of the way in which man will, on some occasions, abdicate his reason, I think a table covered with the different forms of stethoscopes would excellently furnish it.

2. *Length and Thickness.* How long should a stethoscope be? Laennec said a foot. His reason for having it so long was that it enabled him to reach the axilla and other remote parts without inconvenience, and to auscultate his patient in bed without stooping much over him. But I think it too long. I think this undoubted advantage more than counterbalanced by the disadvantage of taking about so cumbersome and inconvenient an instrument. At the same time, to make a stethoscope too short robs it of one of its uses. I have a very simple rule as to length; namely, to have my stethoscope just a little bit shorter than the long diameter of the crown of my hat; and for this simple reason, in order that I may carry the one in the other. It happens to be a very convenient and usual length, and even if it were not, this method of portage would reconcile me to it. If the instrument is just the least bit shorter than the crown of one's hat, and after putting it into the top of the hat directly antero-posteriorly a little twist is given to it, it sticks firmly and is safely supported. Some people revile this practice of always carrying about one's stethoscope in one's hat, and call it unprofessional and shoppy; but it has this great advantage, that you and your stethoscope are never far apart; for where your hat is there is your stethoscope, and in this climate a man is as likely to be without his head as without his hat.

With regard to thickness, extreme thickness and extreme thinness have both their disadvantages. A very thick stethoscope is unnecessarily heavy, and a very thin-walled one is, I think, hypervibratile, and gives a modified tone; while, at the same time, it is an extravagantly fragile instrument.

It has been a subject of debate whether a solid stethoscope is best, or one with a hole bored through it. I think myself it is a matter of indifference. I have carefully examined the relative conducting properties of two cedar stethoscopes, of exactly the same size and shape, but one solid and the other

hollow, and have failed to detect any difference between them. Laennec attached great importance to this point. He believed that the central hole was necessary for the conduction of the voice-sounds, while the heart-sounds were conducted best through a solid cylinder, the breath-sounds being audible through both, but best through the hollow instrument. I cannot but think that here this great observer has been guilty of an over-refinement. I find the sounds of the heart conducted as well through a hollow stethoscope as a solid one, and the voice-sounds as well through a solid as a hollow; provided, always, the instrument be of the proper material, and there be no other vice in its construction.

3. *Size and Shape of Extremities, etc.* And now I come to the most important point of all, that upon which the properties of a well- or ill-constructed stethoscope chiefly depend.

First, the chest-end should be small. There is no commoner fault in stethoscopes than having the chest-end too large. There are two reasons why it should be small: in the first place, the smaller it is the greater is the power of circumscription of the instrument, the greater its localising power, the narrower the limits within which it determines the seat of a sound. For it is manifest, if a sound is covered by a stethoscope whose chest-end is two inches in diameter, that the area in any part of which the seat of this sound may possibly be placed is four times as great as if a stethoscope were used whose chest-end was an inch in diameter, and that the smaller the chest-end of the instrument the sooner will the auscultator be aware (in exact proportion to the smallness of the end), in passing to right or left, up or down, that he no longer covers the sound. But a more important reason for the smallness of the chest-end is, that the larger it is the more is its perfect apposition impeded by the inequalities of the chest. It is fatal to auscultation that there should be any chink between the stethoscope and the chest-wall; if there is, and the air within the instrument is not perfectly shut off from communication with the outer air, we get that well known humming noise which we hear on applying a shell to the ear. In a fat chest, or an even chest, or a well fleshed-up chest, a wide-ended stethoscope would not be attended with this special disadvantage; but in a thin chest it would be impossible to maintain perfect apposition, and preclude chinks in the intercostal spaces, the sub- and supra-clavicular regions, and over a very hollow sternum, unless the chest-end of the instrument were quite small.

Fig. 1.

Suppose, for example, that  $x, x$  (Fig. 1) represent the prominences of two ribs in a thin

chest, and  $z$  the deep intercostal space between them, it is manifest that if the chest-end of the instrument is wide enough to extend from rib to rib it will be so lifted at the edges placed on the ribs ( $x, x$ ) that in the interval, where the integument sinks in between them, a wide chink will exist ( $a$ ); just as the *President* steamship, which was lost some years ago, is supposed to have "broken her back," from being so long that her stem and stern rested on two great seas, and so, in the intervening trough, hoisted her out of the water; thus she was unsupported and parted amidships. If she had been half the length this could not have happened, for then she would only have been the length of a single sea, and not two seas, and would have rested in an inclined direction on one or other of them. In the same way, if the chest-end of the stethoscope is so small that it cannot cover two ribs (*i.e.*, not so large that it *must* cover two ribs) it may, by being inclined one way or the other, secure perfect apposition on the most uneven chest; for while one edge is tilted up by the rib the other sinks into the integument in the intercostal space, as shewn in fig. 2.

Another important attribute in the chest-end of a

stethoscope is the character of its edge. It is a great mistake to have, as one often sees, a wide, flat edge; the wider and flatter the edge the more difficult, manifestly, its perfect apposition, on the principle I have just enunciated. The edge should be narrow and smoothly rounded, as seen in fig. 3, A; narrow to neutralise the effect of inequalities, rounded so as to prevent any sharpness and obviate pain to the patient. One often sees such a chest-end as is represented in section at fig. 3, B, which is doubly bad; bad from being broad and flat and so producing chinks, and bad from having a sharp cutting edge.

The ear-piece should be large for the very same reason that the chest-end should be small—to secure apposition and occlusion; for, the larger it is, the less critically exact and central need the apposition of the ear to it be, in order to prevent chinks and a want of coincidence between them. The smaller the ear-piece, the more are divergencies from exact central application attended with imperfect closure. In

fact, it is a very difficult thing so to apply the ear to a very small ear-piece as to produce perfect occlusion.

Moreover, the ear-piece should be flat. It is often cupped and hollow; this makes perfect apposition of the ear next to impossible. If there is any divergence from perfect flatness the surface should be rather projecting in the centre than receding; the parts about the centre of the pinna are thus brought into firm apposition with the stethoscope, and perfect occlusion secured. But, on the whole, I prefer that the ear-piece should be perfectly flat.

Fig. 4.

Fig. 4 represents the section of what I consider a very good stethoscope. It is half the "natural" diameter, *i.e.*, one-eighth the size. The ear-piece is flat and broad, and the most careless application of the ear would produce perfect occlusion; the chest-end is small, with a narrow and rounded edge. The measurements are—length seven inches, diameter of ear-piece three, diameter of chest-end one and a quarter, circumference of shaft one and a quarter.

[To be continued.]

ALLEGED DEATH FROM IMPURE VACCINE LYMPH. The Registrar-General reports, in the returns of the week before last, that a child died from the effects of impure vaccine lymph. This registration-fact requires explanation.

GROWTH OF QUEENSLAND. At the date of our own last census—the beginning of April 1861—the population (not aboriginal) of the colony of Queensland was 30,059. On the 30th of September last, it was 41,941; namely, 25,435 males, and 16,506 females. At this rate, the population would double itself in less than four years; but such an increase depends, of course, mainly upon immigration.

# Facts and Arguments

OPPOSED TO

## DR. BENNETT'S THEORY OF ORGANISATION.

BY

LIONEL S. BEALE, M.B., F.R.S.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS; PROFESSOR OF PHYSIOLOGY AND OF GENERAL AND MORBID ANATOMY IN KING'S COLLEGE, LONDON; PHYSICIAN TO KING'S COLLEGE HOSPITAL; HONORARY FELLOW OF KING'S COLLEGE; ETC.

THERE are few questions of greater interest to those who are investigating the principles upon which medicine is based, than many now being discussed in the lectures of Professor Bennett of Edinburgh, in course of publication in the *Lancet*. As a fellow labourer in the same field of inquiry, I trust I may be permitted to point out one or two apparent discrepancies or inaccuracies, which seem to me to require further explanation.

Dr. Bennett says that development and growth are owing to the successive formation of *histogenetic and histolytic molecules*. He describes how the first may be formed from the union of two simple organic fluids, or from precipitation occurring in formative fluids holding various substances in solution. Histolytic molecules are distinguished from the histogenetic molecules as follows:—"They are often larger in size than histogenetic molecules, are more purely fatty, and from being sometimes associated with the *débris* of broken down texture, may, in such cases, be readily distinguished." Accordingly, the reader may compare fig. 4, showing "histolytic molecules mingled with *débris* of tissue," with fig. 1, "minute histogenetic molecules." But this very same fig. 1 has been described in other works by Dr. Bennett as "minute molecules frequently seen in disintegrated tubercle." Dr. Bennett describes differences between molecules of formation and molecules of disintegration, and yet makes the very same figure represent both. It is true that Dr. Bennett holds that histolytic molecules may become histogenetic molecules; but surely he will not maintain that lifeless particles become aggregated together, and form a living mass, although he has said, "The physical relations I have pointed out are only necessary preliminary steps for the addition of that unknown force we call vitality, which directs the ultimate form these structures assume." (*On Cancerous and Cancroid Growths*, p. 141.)

Dr. Bennett seems to ignore the use of the high powers which are now employed for studying minute points of this kind, and reproduces figures more than ten years old magnified by powers (250 diameters) far lower than those used by observers in the present day for investigating the structure even of fully formed solid tissues.

The molecules "vary in size from the four-thousandth of an inch (a little less than a blood-corpuscle) down to a scarcely visible point, which may be calculated at less than the twenty-thousandth of an inch." Objects of the first diameter appear only as molecules under an inch power, while the mole-

cules, one twenty-thousandth of an inch in diameter, are perfectly measurable when examined under high powers. Surely the term molecule can scarcely be properly applied to a body nearly as large as a blood-corpuscle.

There are many independent living organisms less than the twenty-thousandth of an inch in diameter, consisting of an external envelope, with matter within of a different character. These molecules live and grow and multiply; but their growth does not depend upon the union, coalescence, or aggregation of the molecules or particles precipitated from fluids, as can be proved by anyone who will examine, with a power of 700 diameters or more, the organisms developed in a little water in which some dead animal or vegetable matter has been placed for some hours. Dr. Bennett, however, describes the formation of vibriones in putrid fluids, thus:—"A scum composed of molecules collects on the surface; gradually several of them unite in minute filaments more or less long, which assume vibratile or serpentine movements."

Although I have often watched such minute organisms with powers magnifying from 700 to 3000 diameters, I have never been so fortunate as to see even two particles unite. The particles are all separate from the very first, and remain so. They grow, not by coalescence, but each absorbs nutriment from the fluid which surrounds it, reaches a certain size, and divides. Thus in a few hours millions result. The pabulum passes into each living particle. The new matter is not added upon its external surface.

As an illustration in favour of his view, Dr. Bennett compares the concentric rings of bone in the Haversian system with the concentric layers of a calculus. "When we compare the concentric rings and laminae surrounding the Haversian canals with the like arrangement existing in calculi and all concretions, there can be little doubt that the mineral deposits in bone are intimately connected with the molecular law of aggregation"; but the laminae of the Haversian system are formed layer *within* layer, while the layers of calculous matter are deposited layer *upon*, or *outside*, layer. The outermost lamina, or that *furthest from the centre*, was *first formed* in the one case; the innermost particle, that which becomes *the centre*, was *first precipitated* in the calculus.

There appears to me some confusion in the definition of a molecule; and Dr. Bennett uses the word in many different senses:—

1. The most minute particles of any substance which exhibit no definite form to the highest powers are molecules.

2. Angular or square particles are *molecules*—"angular, square, and of various forms".

3. Spherical particles of the same composition in every part are *molecules*.

4. Particles, the outer part of which possesses properties and composition different to that which is within, are *molecules*.

5. Vibriones, the minute sporules of fungi, etc., are *molecules*.

So that we have large and small molecules, living and dead molecules, simple and compound molecules; molecules of simple, and molecules of complex composition; molecules springing from pre-existing molecules; molecules precipitated from

fluids; molecules which are visible to the histologist, and as large as the 1-4000th of an inch in diameter; and the ultimate molecule, which has "never been reached, even with the highest magnifying powers."

Most of these molecules have totally different properties. Dr. Bennett should therefore state if molecules of the same kind, or molecules of different kinds, become aggregated together.

But, to limit the discussion to one point—the formation of vibriones—Dr. Bennett maintains that several of the molecules forming the scum *unite* to form minute filaments. I do not think that any one has ever seen even two such living molecules together.

### THE THIRTIETH ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

[Held in LONDON, AUGUST 5th, 6th, 7th, and 8th, 1862.]

#### OBSERVATIONS ON THE OCCURRENCE OF MALIGNANT PUSTULE IN ENGLAND: ILLUSTRATED BY NUMEROUS FATAL CASES.

By WILLIAM BUDD, M.D., Clifton; Honorary and Consulting Physician to the Bristol Royal Infirmary.

"Le médecin doit, dans ses premières études, jeter un coup d'œil sur les animaux qui se rapprochent le plus de l'homme."—*Chausier*. (Adopted from Régnier.)

[Continued from page 87.]

As the malady is generally readily curable by decisive measures in its early stage, but is almost as generally incurable if this stage be allowed to pass without them—as the alternatives of death or recovery, therefore, depend on its early recognition—I have thought it a duty to bring the particulars of these cases (so far as I possess them) before the profession, in order that the attention of medical men may be directed to the subject.\*

CASE I. On Oct. 21st, 1856, I was summoned by Dr.

Robertson, of Terrell Street, in this city, to see a patient whom he had visited for the first time the day before, and whose case had put on a strange and formidable aspect.

The subject was a married man, rather more than thirty years old, who had for some years been employed as compositor in the office of the *Bristol Times*, and who, at the time of his seizure, was in good health. The disease under which he was now labouring had begun six days before, in the form of a pimple surmounted by a small vesicle, and seated on the upper lip. His attention was first called to this pimple by the severe itching it occasioned, and which annoyed him very much by interfering with his work. In his attempts to relieve this sensation by scratching the part, the vesicle was soon broken; a circumstance which led the patient himself to form a very definite theory of his case. The printing office had lately been supplied with a fount of new type, and the notion was that the hand, soiled with the new metal, had, in its frequent contact with the broken surface, poisoned the lip.

The same notion, under some other form, occurred in most of the other cases. The fact is worth noting, as showing that the nature and succession of the morbid changes involuntarily suggest the idea of a poisonous inoculation, even to non-professional persons.

In the course of the day, the swelling and hardness gradually extended; and on the day following, they were so considerable as to cause much disfigurement. It is important to remark, however, that apart from the local discomfort, the patient did not at that time feel ill, but continued to work as before. The malady was still in what the continental writers call the local stage.

On the third day, it had begun to spread widely over the face, and the patient was unable to leave the house. From this stage, it passed rapidly to that in which I first saw it, three days afterwards. The aspect of the disease was then very striking, and was unlike anything I had ever seen before. The lips were, at least, four times their natural thickness; of a deep violet, approaching to black; and as hard as brawn. This state of things extended to the whole circumference of the mouth, from the nose to the chin. The closure of the mouth being imperfect, saliva was constantly drivelling from it. On the space between the upper lip and the nose there were three or four small vesicles, containing a little reddish yellow serum. The temperature of the part was considerably below the normal standard. The rest of the face, the forehead, and throat, were also much swelled, and presented very exactly the appearance which these parts have in bad cases of erysipelas. Passing from the mouth to the cheeks, the deep violet of the former gradually shaded away into a dusky red, and the scirrhus hardness gave place to a puffy swelling. The nose participated but little in the morbid change. The enormous prominence of the mouth, its hard and rigid state, and its almost black colour, caused a peculiar and hideous disfigurement, which was in the highest degree characteristic. The general symptoms bespoke rapidly failing powers. The pulse was more than 140 in the minute, and so feeble that it could scarcely be counted. The breathing was rapid; the belly tympanitic; and the body was bathed in a colliquative sweat. The breath exhaled a peculiar and disgusting foetor, which, to my own sense of smell at least, was entirely new. The mind remained perfectly clear. A deep incision was made through the upper lip and carried into the cheek. The incised tissues were so hard that they creaked under the knife. But little blood flowed from the wound, the local circulation having, apparently, very nearly ceased. There was no trace of pus, but a serous exudation oozed freely from the part. Stimulants were ordered in liberal doses.

On leaving the patient at eleven o'clock at night, I appointed to see him again early in the morning; but he

\* In the Twenty-first Annual Report of the Registrar-General, in a table of the causes of death registered in England in each of the nine years from 1850 to 1858 inclusive, the following are the numbers set down to carbuncle: 131, 161, 233, 252, 300, 255, 253, 252, 246. As there is good reason for believing that these numbers may be taken to represent, approximately at least, the proportion of cases of malignant pustule in each year, they would seem to indicate that the disease is on the increase. It is obvious, however, that these statistics cover too small a period to allow of any general inference being founded upon them. Much greater fluctuations are observed in other zymotic diseases in virtue of the common variations to which the whole group are subject. Unfortunately, no data exist from which the most distant approximation can be made as to the concurrent prevalence of the epizootic from which the malignant pustule is derived. The scientific study of veterinary medicine is too recent in this country to render the necessary records possible. We have already seen that there are good grounds for believing that joint murrain has prevailed in England from a very remote age. If there be some doubt whether in England generally malignant pustule has increased of late years, there seems to be none that in London it has greatly done so. In the Registrar-General's Report of the Health of London in 1858, the following passage occurs:—"The deaths from carbuncle were 61; fewer than in 1856, but ten times as many as the deaths from the disease in the earlier years. This troublesome plague of boils has been prevalent for some time." I shall hereafter give some reasons which render it probable that the flesh of diseased beasts is sent to great towns more largely now than formerly. (See the Report referred to, pages xl and 206.)

died in the course of the night. Decomposition set in very early, and advanced with unusual rapidity in the dead body.\*

The rapid way in which life was destroyed by a disease that in its origin appeared so trivial; the peculiar manner in which the deadly influence of the disease was extended from the minute point in which it first appeared; and, lastly, the hideous and very uncommon aspect of the local morbid change, made a deep impression on all who saw the patient. In my own mind, it excited much speculation as to what might be the possible cause of so horrible a death. It was not, however, until I saw a second case, that I identified the malady as the malignant pustule of the French pathologists.

CASE II. On the 18th March, 1859, Mr. Exley, the principal of one of the leading schools of this town, called on me to ask me to visit one of his pupils, in consultation with the late Mr. Wilson of Clifton. From the description which Mr. Exley gave me, I at once recognised the disease as the same which had proved fatal to the compositor whose case has just been related.

The subject was a fine young man seventeen years old. Five days before the date of my visit, his attention was first drawn to a small pimple on his upper lip by the uncontrollable itching it occasioned. On examining the spot narrowly the same evening, he observed that the centre of the pimple was occupied by a small vesicle. This vesicle he punctured with a penknife, and a little serum issued from it. On the following morning, the lip, in a circumscribed spot, was swelled and discoloured. There was, at that time, no general disorder of any kind. He dined at the usual hour with the rest of the school, ate heartily, and was in good spirits. In the course of the next day, three or four small vesicles made their appearance in the space between the nose and upper lip. As the swelling had increased, and the part looked inflamed, it was thought prudent that the patient should keep his bed. It was not, however, until the day following that it was considered necessary to send for Mr. Wilson. The whole mouth now was much swelled and of a purple colour, and the lips were hard and tense. From that time the march of the disease was very rapid.

When I saw the patient two days afterwards, it was in appearance, and in almost every other respect, precisely what I had witnessed in the former case. I have never seen two cases of any other disease so absolutely alike. There was the same erysipelatous swelling of the forehead and face; the same enormous thickening, and black and hardened condition of the lips and mouth; giving rise, by the inordinate prominence of this feature—as if by some monstrous exaggeration of the negro type—to the same hideous and characteristic disfigurement. On the space between the upper lip and nose, there was the same crop of three or four small flat vesicles containing a straw-coloured lymph. Saliva was constantly drivelling from the mouth, and the breath had the same peculiar fœtor. The only difference I could detect was, that in this young man, the mouth and lips were, as yet, hot, and that extending from the ramus of the jaw, down the neck on either side, were several dark red streaks, marking the course of inflamed lymphatics; a circumstance which might have existed, but was not noted in the former case.

The pulse was 120 in the minute; the inspirations were forty-four. Rapid breathing was in both cases a leading feature of the disturbance. The belly was tym-

panitic. The patient had ceased to take much note of things about him; but when he was aroused, the mind seemed to be tolerably clear.

On making a deep incision into the upper lip, no pus issued; but there was a considerable flow of blood, of which as much as eight ounces were lost. The immediate result was a marked diminution of the local turgescence, and a palpable weakening of the pulse. This was at two o'clock in the afternoon. When the patient was seen again, four hours later, he was much worse. The mouth and lips were now cold; the pulse was 140; the inspirations were 64. When questioned, his answers were rational; but when he was left alone the mind wandered. The body was bathed in sweat.

From this time, he sank rapidly, and he died soon after daybreak the next morning, about sixteen hours after I first saw him. Thirty-six hours afterwards, the decomposition of the dead body was already far advanced.

At the time of his death, this young gentleman bore on his left leg the remains of a large boil, which had appeared about a fortnight before. This boil had followed exactly the common course of such things, and had led to none of the peculiar and deadly changes in surrounding textures and in the system at large, which followed the pustule, or, to speak more correctly, the vesicle on the lip.\*

CASE III. On Sept. 11th, 1861, I was asked to meet Mr. H. Grace of Kingswood in consultation on a case which proved to be one of malignant pustule. The subject of it, a clerk in a provision warehouse in Bristol, was a powerful, robust man, about 30 years old, who had always enjoyed good health.

Six days before the date of my visit, while he was in the act of combing his moustache, the comb stuck in a tender part. On withdrawing it, he found that the teeth of the comb had punctured a small vesicle, giving issue to a little yellowish-looking fluid. This accident was the first intimation he had of the existence of the disease which was so soon to prove fatal to him. The vesicle was situated on the upper border of the moustache, immediately below the left nostril. A slight depression and a small dried pellicle still marked its former place when I first saw the patient.

Immediately after the puncture, the part became the seat of a hot, stinging sensation, which lasted all day, and annoyed him very much, and which he described as being very peculiar. There was no itching strictly so-called.

In the course of the day, the lip began to swell, and towards night became very painful. In the night, the pain was so severe that he could not sleep, and he got up more than once to bathe the lip in the hope of relief.

The next day, the swelling had somewhat increased, and the part had begun to look angry. The uneasiness was so great that he found some difficulty in getting through with his work. On both days, however, he walked to and fro to the warehouse (a distance of rather more than two miles each way) and took his usual food.

On September 7th, the pain had much abated; but the swelling and discoloration had increased; the disfigurement was considerable; and, for the first time, he did not leave the house. Apart from the state of the lip, he did not, however, feel very ill; and, up to that time, neither he nor his friends had the slightest idea that the malady was at all serious.

In the night of the 7th, that is to say, on the third day of the attack, he was seized with severe stitch in the right side, and great difficulty of breathing. On the following morning, Mr. Grace saw him for the first time.

The whole of the upper lip was then much swelled,

\* Virchow and many other writers lay great stress on this as one of the characters of malignant pustule. In the animal this tendency to putrescence is manifested even before death by the extrication of stinking gases in the affected part. Virchow also states that, as the disease advances, colourless corpuscles abound in the blood; and he makes the still more remarkable assertion, that numerous vibrios may be seen in that fluid immediately on its withdrawal from the vein of the infected man or animal.

\* Bourgeois has very justly remarked that "the malignant vesicle" would be the fitter name for the disease, since one of its most special characteristics is, in all cases, the absence of true pus—at any rate, in the first stage.

hard, and discoloured; the appearances being such as to lead Mr. Grace to suppose that the case was one of carbuncle. The pulse was somewhat frequent and the breathing difficult. The pain in the right side was very acute, and the physical signs of pleurisy were present.

In the course of the day, a new crop of vesicles, to the number of five or six, made their appearance, chiefly on the right half of the lip.

From this time the disease did not make much progress locally, until September 10th, when the swelling rapidly extended to the whole of the face.

When I saw the patient on the day following, the state of things was in the highest degree characteristic. The lips were more than three times their natural thickness, as hard as brawn, cold, and of a deep livid red, verging in parts into purple and black. The mouth projected at least two inches beyond the rest of the face, giving rise to the same hideous and characteristic disfigurement noticed in the two former cases. The lips, from swelling and loss of muscular power, were imperfectly closed, and a viscid saliva constantly drivelled from between them. The rest of the face had exactly the aspect which it presents in severe forms of erysipelas; the hardness, so extreme in the mouth, shading away gradually into swelling of a softer character. The eyelids were bloated and puffy, and the eyes permanently closed. Above the eyebrows there was no diffuse swelling, but four or five broad, dark red streaks, marking the course of inflamed lymphatics, traversed the forehead from the face upwards, and were lost in the hair. Scattered over the upper lip—chiefly in the space between the lip and the nose—were several small, thin scabs, occupying the former seat of so many vesicles. The case was, in all its details, precisely what I had witnessed in the two other cases in which I had been before consulted. The pulse ranged from 132 to 140; the inspirations numbered 44 in the minute. The body was covered with a profuse, clammy sweat, and the vital powers were sinking from hour to hour. The breath had a very peculiar and repulsive odour, which I recognised at once as identical with what I had smelt in the two former cases. The pain in the right side had nearly ceased, but there was severe stitch in the left, and the patient complained of great difficulty of breathing. He was not in a state to admit of a complete examination; but I ascertained that air penetrated the lower half of the right lung very imperfectly. An obscure rubbing sound was audible over a small space on the left side, below the precordial region. As in the two former cases, I had no opportunity of examining the urine. The mind was quite clear; and the patient took freely and willingly strong beef-tea, brandy, and eggs, and other stimulants.

A stick of potassa fusa was held firmly on the upper lip at four different points where vesicles had existed, until the tissues were destroyed to a considerable depth. A long, deep furrow was produced on the lower lip by the same means. There was a slight oozing of serum from all these parts, but no single drop of blood appeared. The circulation in them had apparently entirely ceased.

The patient continued to sink rapidly and died on the 12th of September; twenty-six hours after my visit, and eight days from the first discovery of the vesicle.

The inflamed lymphatics, the double pleurisy, and the rapid and terrible death, all occurring as the consequence of an affection which, a few days before, was nothing more than a vesicle so minute and insignificant as even to be discovered by accident, are circumstances which sufficiently mark the nature of the disease, and are of deep import in relation to its pathology. If I do not misinterpret the phenomena, they testify at once to an inoculation by a malignant poison, and to the intensely virulent nature of the morbid agent.

A circumstance deserves to be mentioned in connection with this case as bearing on its possible origin. About

a week after the death of this young man, I was informed by his friends that he himself had a settled conviction that the pustule was caused by the use of a new pomatum which he had bought about a week before his illness, and had rubbed very freely into his moustache. As tallow-chandlers and soap-boilers have long been known to be frequent sufferers from malignant pustule in the countries where the corresponding epizootic is rife, it is quite possible that this view might be the true one.\* As the patient was employed in a provision warehouse, it is equally possible, however, that he may have become infected in the exercise of his calling.

For the particulars of the next case, I am indebted to my friend, Mr. Green, senior surgeon to the Bristol Royal Infirmary. The facts are related in his own words.

CASE IV. On May 4th, 1854, I was sent for to see Master E., who was said to be suffering from swelled face. He was a tall, delicate youth, 17 years old, and had been for some months out of health, having come to Bristol for change of air.

I found the entire right side of the face much swollen. The lips, in particular, were very large and projecting and of a purple hue. On the margin of the upper lip, there was a small pimple covered with a scab. The parts were very hard, especially immediately around the pimple. The right eye was closed by the swelling. The pulse was quick, and the surface hot; the tongue brown and moist.

The disease had begun three days before with a small vesicle on the upper lip, which the patient had broken by scratching. The day before I saw him, the swelling, which was before confined to the lip, had extended to the face; and as it went on increasing, the friends decided on having medical aid. From the aspect of the face, as well as of the patient himself, I looked upon the case as something different from ordinary inflammation.

On the day following, the disease had made great progress. The swelling had extended, and the affected parts, especially in the neighbourhood of the original pimple, were very dark in colour, and much indurated. The prostration was great.

At this visit, the real nature of the disease first occurred to my mind. I remembered once having seen a similar case in the wards of La Charité in Paris, which was made the subject of some clinical remarks by Roux, and I at once recognised the malady as the "pustule maligne" of Delpech and the French writers.

I told the friends the serious nature of the case, and recommended a consultation, which they wished deferred until the morrow, when the patient's father was expected. As the danger to life did not then appear to be great, I consented to this arrangement.

I made a deep incision through the indurated part, which was evidently losing its vitality, as very little blood flowed in consequence. Tincture of muriate of iron was applied to the wound. I saw the patient late at night, and found his condition but little altered.

About 4 A.M., he became very much worse, and at 8 A.M., I was sent for to see him. The entire face was then of a livid colour, approaching to black; the pulse

\* Es ist eine alte Beobachtung (writes Heusinger) dass Seifensieder und Lichterzieher oft an Milzbrand-Karbuikel erkranken, wenn sie Talg von am Milzbrand krepirten Thieren erhalten. So erzählt denn auch Hil ebend einen merkwürdigen Fall: zwei Schäferweiber erkrankten dadurch, dass ihnen beim Ausstreuen des Talgs von an der Blutsuche krepirten Schafen dieses Fett in das Gesicht spritzte. Aehnliches berichtet Wagner. Als man den gewonnenen Talg (von einer milzbrandkranken Kuh) angetrungen hatte, wurden die Griefen dazu benutzt zwei Schweine, zwei Hunde, und eine Katze damit zu laben, drei Thiere starben bald nacher, und zwar die Katze unter herum Wälzen auf kühnen Rasen. (P. 400, u. s.) If these statements can be relied on the temperature to which tallow is raised in being melted would appear to have no power to destroy the virus. I have ascertained that in making certain varieties of pomatum, and particularly those in which trotter oil is used, the ingredients are mixed at a comparatively low heat.

was hardly perceptible; the body was bathed in sweat. It was evident to all that he was fast sinking; and he died at about 11 o'clock, five days after the first appearance of the vesicle.

The general treatment consisted chiefly in the liberal administration of good beef-tea, brandy, and ammonia.

[To be continued.]

## Original Communications.

### DISLOCATION OF THE KNEE-JOINT.

By T. OGIER WARD, M.D., Cowbridge.

As dislocations of the knee-joint are rare, I send an account of one in which reduction was effected by flexion instead of extension, the latter having completely failed.

A young gentleman, aged 15, riding a velocipede down a steep hill, was thrown off, and fell on his left knee. He walked home, and four hours afterwards came to me, when I found the knee very much swelled from effusion into the joint, the patella projecting about an inch, and half an inch lower than the right from the tension of the ligament. The limb was straight, and could not be flexed without pain, though painless when quiet and extended. A side view of the limb showed little difference between the left and right behind; but in front the prominence of the patella clearly proved that the tibia was dislocated backwards. There was a bruise and abrasion of the skin over the internal condyle. The limb was not shortened; indeed, if at all, it was longer than the other.

Thinking that, with so little change in the form of the limb, the reduction by extension would not be difficult, I first tried that plan; but, though I put the patient under the influence of chloroform, and gave him several half-grain doses of tartar emetic, and had two strong men making extension with a roller-towel round the ankle, at the same time that I was trying to push the head of the tibia forwards, not the least effect was produced. I then recollected that I had formerly reduced a similar case, where the patella was fractured, by flexion of the joint over the knee of an assistant; so, taking the towel off the ankle, and thus diverting the attention of the patient, I suddenly pushed the heel backwards till it touched the thigh, when the reduction was completed, and the power of flexion was restored. I then bound a slight splint round the extended limb; and, with the aid of cold lotions, in a few days the effusion was absorbed; and in three weeks the cure was completed, and the bandage was removed.

The rarity of this form of dislocation, and other peculiarities in the symptoms and treatment, suggest a few remarks. I have before me the descriptions of two of the most recent writers on this subject, Mr. Erichsen and Mr. Lane. The former states (*Science and Art of Surgery*, 3rd edition, pp. 290-291): "The dislocation backwards of the tibia may be complete or incomplete. When it is complete, the posterior ligament of the joint is torn, the muscles of the ham are stretched, the limb is shortened to the extent of an inch and a half or two inches, and is semiflexed; the head of the tibia can be felt in the ham, and there is a deep transverse depression in front of the joint immediately below the patella. . . . The antero-posterior dislocations are very commonly incomplete. When this is the case, they present the same symptoms, but in a less marked degree, that characterise the complete displacements." In treatment of dislocations of the knee, Erichsen recommends "extension from the ankle while the thigh is fixed in a semiflexed position".

In this account, the possibility of the limb being lengthened is overlooked; and the treatment is the same as has been recommended by all previous writers—viz., extension of the affected limb.

Mr. J. Lane also (Cooper's *Surgical Dictionary*, 1861, article Dislocations), quoting Malgaigne, omits all mention of the lengthening of the limb; but to the recommendation of extension, Lane adds: "Should any difficulty occur after the necessary extension has been made, the effect of flexing the knee may be tried; or the knee may be bent round the bedpost, or over the left arm or knee of the operator." He makes, however, no distinction as to the class in which flexion is best.

In describing the incomplete luxation backwards, Mr. Lane, or Malgaigne, asserts that "the limb is sometimes extended, sometimes slightly flexed," which latter position seems impossible, unless the ligamentum patellæ be ruptured; and therefore, I think, in this respect he has confounded the dislocation of the semilunar cartilages (of which, slight flexion with inability to extend the knee, is the pathognomonic symptom) with incomplete luxation of the tibia backwards. Sir Astley Cooper's description, omitting the shortening of the limb, is most characteristic—"a projection of the condyles of the femur, a depression of the ligamentum patellæ, and a bending of the leg forwards"; but he also recommends only extension for the reduction.

My own case agreed with Sir A. Cooper's description, except as regards the shortening of the limb and depression of the patella; which, however, might be said to be depressed at its lower end under the extremity of the femur, while the upper part was raised by the effusion beneath and the tilting up produced by the depression of the other end. In this, as in the former case I have alluded to, the nature of the injury was evident from the bending of the leg forward; and yet in neither instance could reduction be made by extension, though it was readily effected by flexion of the limb. How are these discrepancies in the treatment and the shortening of the limb to be reconciled? Only, I think, by considering the cases requiring flexion for their reduction as incomplete luxations, and those reduced by extension as complete luxations attended with rupture of the ligaments. This view will explain the facility of the reduction of the latter (for, the ligaments being ruptured, there would be less power of resistance to the extension); and, *vice versâ*, the very great difficulty, if not impossibility, of the reduction by extension when the luxation was slight and the ligaments uninjured. In proof of this difficulty, I recollect seeing a boy of 15, who had dislocated the semilunar cartilages, resist with ease the united efforts of six persons to straighten his knee, which, as usual in that accident, was bent, though the power to straighten it returned after a few days rest.\* In the last case of execution in France by the victim being torn asunder by four horses, each attached to a limb, the utmost efforts of the animals failed, until the ligaments had been divided.

It is hardly necessary to state that luxations not attended with rupture of the ligaments would require very little treatment after reduction. Again, the reduction of any case by flexion necessarily implies only a slight displacement of the ends of the bones; for, if the head of the tibia were pushed far backwards, flexion could not be effected without fracture of the patella or rupture of its ligament. The slight displacement may also explain the absence of shortening of the limb, and account for its being lengthened; for, if the condyles of the femur were thrown upon, and rested on the anterior tuberosities of the tibia, instead of on the hollow sur-

\* Though Sir A. Cooper recommends flexion of the knee in dislocation of the semilunar cartilages, reduction will take place spontaneously in a few days by the gradual stretching of the tissue connecting them with the capsular ligament, and thus a painful operation may be avoided.

faces behind them, the limb must necessarily be lengthened.

If these statements and arguments are correct, it seems to be proved that, in incomplete luxations of the tibia backwards, flexion, and not extension, is the easiest mode of reduction, and that in such cases the limb may be lengthened.

P.S. As there seems to be a question respecting the influence of bleeding or loss of blood in the production of softening of the brain, I may mention that I was recently called in to a woman who had a "fit" on the ninth day after a *very easy labour, with very little loss of blood*. I found her slightly paralysed in the right hand and arm, but unable to speak plainly, or to find the right word to express her meaning. The left pupil was natural, perhaps a little dilated; but the right was very much contracted. Since the attack the previous night, she had vomited, and had diarrhoea, the last motion being bloody mucus. I ordered her a chalk mixture with laudanum, the first dose of which stopped the vomiting and diarrhoea. The next (third) day she complained of pain in the left side of her head; and I ordered four leeches, which were not applied till the night of the fourth day, when only two drew blood, at the outer angle of the eye, about six o'clock. At 11 p.m. she had another fit, became insensible, and remained so till her death, twenty-four hours after the attack, with occasional convulsive movements of the affected arm. I saw her twelve hours after the attack, when the eyes presented the same appearance. I did not examine the head; but the symptoms clearly point to softening of the brain, rather than apoplexy; and I cannot believe that the small quantity of blood drawn by two leeches could have caused a recurrence of the "fit". Her eldest son has epileptic fits; and I am disposed to attribute the mother's disease to perhaps a tendency to disease of the brain, increased by grief at the recent death of her father, and brought to a climax by the straining of even an easy labour. The absence of pain till after the fit is accounted for by the insensibility of the cerebral substance.

## CASE OF PELLAGRA.

By SAMUEL WILKS, M.D.

THE observations of Dr. Peacock on pellagra, contained in the last number of the *Medico-Chirurgical Review*, have again brought before my mind a case which I witnessed last autumn, and which I suggested might be an example of an affection which is almost peculiar to the north of Italy. No English author that I am aware of, has ever described such a form of disease in this country, and, therefore, it is with considerable diffidence that I bring forward the present case as an example of it; at the same time the case so much resembles the descriptions which I had read of this remarkable malady, that I informed the medical man under whose care the patient had been, that I could make nothing of it unless it were a case of pellagra. The report of the case, although brief, may be the means of drawing some similar instance from the note-books of other practitioners. I believe it to be true that many diseases which are rife in some countries, and almost peculiar to them, may occur in isolated instances, and in modified characters, in other parts of the world; and, thus it is that elephantiasis or leprosy may be sometimes met with in our own temperate island. In the same way, pellagra, which is described by French writers as not occurring in Paris, yet was supposed to exist in the persons of four patients which were in La Charité some years ago. (M. Willemin in *Archives Générales de Médecine*, Series 4, vol. xiii.)

The disease, as it is witnessed in Italy, is an affection

of a very chronic nature, continuing for several years, characterised by a general wasting of the body, and by a rash which covers the exposed parts of the skin, commencing as an erythema, and progressing into a lichenous or eczematous eruption. At a later period, sores sometimes appear, impairment of digestion, and nervous symptoms, as paralysis of the limbs. The cause of the disease appears at present not decided, it having been thought by some that it is due to exposure to the sun, from the fact of exacerbations occurring in the summer time; by others, that it is due merely to poverty, as it does not prevail amongst the rich; but these and similar supposed theories, are refuted by the remembrance that such causes are not peculiar to Lombardy, but exist where pellagra is quite unknown. The most recent theory places the cause in the consumption of diseased maize, the corn being affected somewhat after the manner of the ergotised rye.

In the four cases which occurred at Paris, described by M. Willemin, and which appeared to be true examples of the disease, the skin was covered either with an erythematous, a lichenous, or eczematous rash. This was on the face and arms, and had a thickly defined margin; in two cases a diarrhoea existed; in one the gums were spongy, as in scurvy, and in some there was a weakness of the extremities. The pulse was feeble in all, and in one case, after the patient had been lying down, was reduced to thirty beats in the minute.

The peculiarities of the disease appear to be: in the first place, this cutaneous eruption, which is remarkable in affecting the parts exposed to the light, as the face, neck, chest, backs of hands, arms, or feet, the redness ceasing abruptly at a line where the covering of the clothes commences; the skin also becoming hard and dry like parchment, and in some cases bullæ appearing. Next in importance to the cutaneous rash, are various nervous symptoms, as numbness or pains in the limbs, and sometimes a veritable paralysis, as in myelitis of the spinal cord. It is said by some writers that in very bad examples of the disease, a melancholy overtakes the patient determining to suicide, especially by drowning, and to this has been given the special name of *hydromania*. Other writers, however, are ignorant of the existence of this propensity. As regards the pathology of the disease, nothing is known; some have regarded it as a chronic *gastro-enteritis*; whilst others, at a loss to discover the seat of the disease, have been content to style it *morbus chronicus totius corporis*.

The case which came before me last autumn, was that of a woman, living at Glastonbury, and intimately known to Mr. Malton of that place. This gentleman sent the case up to his relative Dr. Charlton of Dartford, who again brought her to me for an opinion as to the nature of her complaint, the obscurity of which suggested to the former gentleman, I apprehend, that there might be some disease of the suprarenal capsules. She was married, aged 33, and had three children. She informed me that she had been ill for six years, having become very thin and being covered in parts with an eruption. She said that her illness had commenced five and a half years before, in the month of May, after exposure to the sun. These statements were not extracted from her by leading questions; for it was not until after she had left my house, and I was revolving the case in my mind, that the idea struck me, that it was one of pellagra. Soon after this exposure to the sun, a rash appeared on the face and arms, and subsequently she lost flesh and became weak. This rash, she said, had continued ever since with varied severity, being aggravated in summer, and better in winter. Her general appearance was very remarkable, presenting as she did a withered and emaciated look, reminding one of a child in the last stage of marasmus; all the outlines of the face were very prominent, the cheeks were sunken in and the temporal muscles much wasted. The face was covered with a

brownish-red rash, not uniform in amount but patchy; this was of a papular or lichenous character, with a slight furfuraceous covering. The neck was slightly affected in the same manner; the forearms as far as the elbows were covered with a similar rash; the skin being rough and affected by a brownish-red eruption. This appeared to correspond to the papules of the skin, and gave a hard dry feel to the touch. The backs of the hands were similarly affected, and, in fact, all those parts which were exposed, whilst those which were covered were free. Her limbs were wasted, and the joints of the elbows somewhat contracted; not admitting of full extension. On the face there was also the scab of a pustule, and on the arm was another similar one. On the right forearm there was also an ulcer, the seat of a former pustule, and which was unhealthy looking and bleeding. I could discover no disease in the body, for tuberculosis suggesting itself, I looked for phthisis and other manifestations of it, but nothing of the kind could be discovered. I also examined for enlargement of the cervical glands which might have obstructed the thoracic duct; nothing could be felt in the abdomen, although I surmised the presence of mesenteric disease. The only nervous symptom was weakness of one arm. The gums presented no marked scorbutic appearance, but were rather too red and swollen. There was no diarrhoea, and she stated that her spirits were good.

It will be seen that the symptoms in this case very closely correspond to those described as belonging to pellagra; and, therefore, no surprise will be felt when I suggested to Dr. Charlton the nature of the disease. If it should not be of this kind it will be found probably due to some morbid condition interfering with the due supply of chyle to the system, and in connection with this, it will be remembered how harsh and withered the skin becomes in children who are wasting from mesenteric disease. It is not surprising, therefore, that the disease has been called (according to Dr. Peacock) *marasmus pellagrosus*, or *tabes pellagrosa*.

Within the last few days, Mr. Malton has written to say that the patient is going on much the same; the wound in the arm is still ulcerating; and she has lost almost complete power of the same extremity. The disease of the skin is better (winter time). Mr. Malton will, no doubt, report the further progress of the case.

## Reviews and Notices.

**THE NATURE AND TREATMENT OF GOUT AND RHEUMATIC GOUT.** By ALFRED BARING GARROD, M.D., F.R.S., Fellow of the Royal College of Physicians; Physician to King's College Hospital; etc. Second Edition, enlarged and carefully revised. Pp. 618. London: 1863.

WHEN the first edition of this work appeared, three years ago, we gave an ample analysis of its contents (JOURNAL, Jan. 7, 1860). It is therefore not necessary for us now to do more than state that Dr. GARROD has in this edition incorporated the results of his increased experience of the nature and treatment of gout; and has added a chapter on the diseases to which gouty persons are peculiarly liable. At the same time, he has pruned down the historical and other less practically important matter contained in the first edition, so that the present volume contains but a few pages more than its predecessor. The work shows traces throughout of careful revision; but the author has nowhere found reason to alter the views formerly expressed by him. His opportu-

nities of testing them, he says, "have only tended to confirm his opinion as to their accuracy."

**CLINICAL SURGERY. ON STRICTURE, RETENTION OF URINE, STONE IN THE BLADDER, AND OTHER DISEASES OF THE URINARY ORGANS.** By THOMAS BRYANT, F.R.C.S., Assistant-Surgeon, etc., Guy's Hospital. London: 1862.

MR. BRYANT here furnishes a continuation of his valuable series of surgical clinical observations. His remarks are here founded on 1077 cases of diseases of the bladder and urethra, admitted into Guy's Hospital between October 1st, 1853, and March 30th, 1861: of these, 1008 were cured or relieved, and 77 died.

Among the practical matters which the author has brought forward, we observe that rupture or laceration of the urethra assumes a very different meaning in the Guy's Hospital practice when it occurs as the result of stricture from that which it has when it follows an injury in a healthy urethra. In the former category, 45 cases occurred, of which 15 died; in the latter were 19 cases, and no deaths. This difference in the result is, assuming the treatment in both classes to be equally prompt, no doubt due to the fact that, in the former class, the urine has been long retained in a distended portion of the urethra behind the stricture, and, when extravasated, has become more or less altered from its proper character: in the latter, when urine is extravasated (which does not always occur), it is urine *pur et simple* that is poured out. In all cases, early incision into the perineum is the practice to be followed; and in cases of extravasation from stricture, Mr. Bryant recommends that the stricture itself be divided at the same time that the incision is made in the perineum. In cases of ruptured urethra from injury, the following is the line of practice recommended by Mr. Bryant, and apparently followed at Guy's Hospital.

"If called to a patient who has evidently been the subject of an injury to the urethra, suffering from simple retention, the first object of the surgeon should be to attempt to pass a catheter; if the urethra is not completely torn away, and there is not much blood locally effused, there will be a strong probability that he will succeed, and, having done so, the instrument should be left and fastened in; a gum elastic instrument, therefore, with a strong stilette, should be employed. If the attempt at catheterism, although having been fairly made, should fail, some other means must be employed; for it is clear that an outlet for the urine must be obtained, or otherwise extravasation, with its dangers, will necessarily follow.

"An incision into the perineum with a grooved staff is unquestionably the soundest practice; by it the extravasated blood and urine, if it exists, finds a ready outlet; and the bladder, when it contracts, will find a vent for its contents, without the dangers occasioned by an extravasation of urine.

"If the orifice of the vesical end of the ruptured urethra can be found with a grooved probe, a catheter should be passed, the instrument having been first introduced through the penis, and subsequently guided upon the grooved probe into the bladder; if difficulty is experienced in finding the orifice, there need be no alarm, as it is quite clear that the urine will readily find its way externally through the artificial wound; an early attempt to pass a catheter should, nevertheless, certainly

be made, for it is most important that the continuity of the urethra should be restored as early as possible.

"When a catheter has been introduced, it must be left in; for it is equally important that the patency of the canal should be maintained during the whole period of its repair, and its subsequent contraction in a measure neutralised. The frequent passage of an instrument after the repair has taken place is an important point to be observed; this practice being the best guarantee that a traumatic stricture will not be the result, and if it be, the risks will be materially lessened."

At a subsequent page, Mr. Bryant again insists on the necessity of dilatation by catheterism after rupture of the urethra, in order to prevent the occurrence of traumatic stricture—an affection which he shows to be less amenable to treatment than stricture arising from other causes.

THE MINUTE ANATOMY AND PHYSIOLOGY OF THE NERVOUS SYSTEM IN THE LOBSTER (*ASTACUS MARINUS*). By T. S. CLOUSTON, M.D., Assistant-Physician Royal Edinburgh Asylum, etc. Pp. 35. Edinburgh: 1863.

THIS is a reprint, from the *Edinburgh New Philosophical Journal* for the present month, of a portion of a prize thesis presented by Dr. Clouston on the occasion of his graduation in the University of Edinburgh. We find here evidence of an attentive study of all that has been done in the matter of the nervous system of the crustacea by previous anatomists, coupled with independent and original observation. The pamphlet is illustrated by two plates, containing thirteen figures representing nerve-tubes, sections of ganglia, etc., as observed by Dr. Clouston. Those who are interested in comparative anatomy will probably derive instruction from Dr. Clouston's account of his researches.

OBESITY. We borrow the following curious cases of this inconvenient affection from an interesting book just published by M. Ferdinand Caunière, entitled *De la Médecine naturelle Indo-Malgache*. In a well constituted adult the proportion of fat is not more than about a twentieth of the weight of the whole body; it may exceed that proportion to a certain extent without inconvenience, but it becomes a regular disorder when it reaches the proportion of one half. Persons have been known to weigh from 600lbs. to 800lbs.; a man spoken of by Wadd had attained the enormous weight of 980lbs. An Englishman, named Bright, mentioned by Coe in the *Philosophical Transactions*, weighed 616lbs. at his death; at the age of 10 he had weighed 140lbs. Bartholin mentions a child of that age who weighed 200lbs. Drs. Percy and Laurent mention a young German woman, who at her birth weighed 13lbs.; at the age of six months, 42lbs.; at six years of her age she could carry her mother, and promised to become unusually muscular. At 20 she weighed 450lbs.; she measured 5 feet 10 inches in height. The circumference of her arms was 18 inches; she could carry 250lbs. in each hand, was active, and could walk for an hour without feeling fatigued. She did not eat more than an ordinary person, drank tea in abundance, and was remarkable for her good humour. In general, obesity is not accompanied with longevity; most people are of a plethoric habit, and the functions of the principal organs are always more or less impeded, which naturally causes various affections. M. Caunière's book contains various curious facts and some useful hints, derived from his experience of the wonderful cures performed by the natives of Madagascar, who only use medicines drawn from the vegetable kingdom, and to whom bleeding, whether by the lancet or leeches, blisters, and cauteries, are unknown. (*Galignani's Messenger*.)

## British Medical Journal.

SATURDAY, JANUARY 31st, 1863.

### GRATUITOUS SERVICES.

A CORRESPONDENT sends us a paragraph from a Leicester paper, which tells of the salary of the chaplain of the Leicester Infirmary; and, in doing so, he takes the occasion of asking what are the grounds upon which a distinction should be shown in respect of payment of the spiritual and not of the corporeal advisers of the patients.

"Leicester", he writes, "is a flourishing town, doing well in wool, fat, and flesh, as regards the market; and does a brisk business not only in the sock and stocking, but also in the shoe trade. It is well to do also in matters medical. It owns about thirty physicians and surgeons, and returns the only provincial member of the present Council of the College of Surgeons, viz., our respected associate Mr. Paget. Its hospital *employés*, who willingly work for nothing, and do much 'free, gracious, and for nothing,' are men who deservedly stand high in the profession. The chaplain, who is concerned only about the souls of the hospital inmates, and has nothing more to do with their bodies than seeing them quietly covered over in decency, is, as you will see, bold enough to ask, at a quarterly court too, for more in the shape of additional pay! He no doubt finds, as Christmas draws nigh, that some of its real concomitants—tradesmen's bills—come in. But how fares the doctor, who at all hours may be called on to quit profitable employment at home, or in his out-door practice, to go on a mission of mercy in body-curing to the distant hospital? At Christmas, he has no cheque for £120 sent on to his banker, to stave off the butcher, the baker, tailor, or draper, all of whom are probably charitable subscribers to the hospital, but sustain only a sort of discount loss in the shape of a couple of guineas, hopefully and profitably invested! Why do nine-tenths of tradesmen subscribe to hospitals, but to enlarge the field of their commercial pursuits? Why do ninety-nine-hundredths of medical men clamour and cry after public service in our hospitals, but for the benefits that are supposed to accrue in the shape of private practice? The subscriber and the medical man, be it remembered, deal only with the frail fabric of the human body. The chaplain is entrusted with the care, cure, and preservation of its immortal soul; and, in his official capacity, may properly be said to be under stronger obligations and heavier responsibilities to the Divine Being to lend himself willingly and *gratuitously* to such a 'labour of love'. But do we find it so?

The present instance furnishes a proof that the medical man will render for nothing more arduous service than can be obtained from the clergyman under anything less than, to say the least, a very handsome and competent stipend.

"What are the comparative responsibilities pertaining to the practice of the two functionaries, regarded from a worldly point of view? Was an action-at-law ever successfully brought against the former for failing in his duty to his patient? or was he ever mulcted in heavy damages for having failed to effect an impossibility? The historical records of our assize-courts prove, on the other hand, that cases in which the medical practitioner has grievously and unjustly suffered, for having so failed to work a wonder or a miracle, are neither few nor far between. With such an immunity from penal consequences in practice, with a substantial pecuniary acknowledgment sufficient to keep him twelve months in broad-cloth, and without any great sacrifice of talent, time, or money, why should the chaplain of a public hospital receive payment for his services, any more than the members of its all-important medical staff?"

#### WHAT IS DISEASED MEAT?

WE every week read of enormous quantities of meat "unfit for food" being destroyed by order of the inspectors of markets in this great London. Every one will rejoice to hear of the vigilance of those officers of health, as we may fairly call them; and we apprehend that there is no fear of such officials erring on the side of over-destructiveness. Nevertheless, as this destruction of "unfit food" is carried on under the protection and in the name of sanitary science, we should much like to have some distinct—i.e., appropriate, scientific—definition given of the meaning of the words "meat unfit for food." We consider that there ought to be some manifest and positive sign, by which the fitness or unfitness of any given article exposed for sale in a market may be at once declared.

We have heard so much of late of the injury inflicted on the people of the country through the ingestion of "unfit food," that we naturally inquire first, what is this unfit meat which they take; and, secondly, what are the injuries under which they, in consequence, suffer?

It appears that the authors who chiefly maintain that great injury is done to the bowels of our humanity by this evil food, are obliged, for the most part, if not altogether, to resort to the writings of Germans and foreigners for individual instances of the evil effects produced. And they maintain that if, in this country, all sorts of violent diseases do not immediately follow on the ingestion, yet, we may be sure, the people are slowly suffering under

the insidious and poisonous action of the vicious food.

Now, in the name of common sense, and for the sake of science, whose name is sometimes unfairly invoked, we would ask for some kind of scientific proof of the position here assumed. Let us have, in the first place, a definition of the terms "unfit food"; and then let us have proofs of its injurious effects on the bowels and bodies of our countrymen. Is all meat which is called unfit really so? "Measly" pork, for example, would, we suppose, hardly escape condemnation; yet is it really true that such pork is unfit for food? May it not be fairly asked, is it not true that roasting and boiling absolutely destroy the vitality of the cysticercus? And when this animal is destroyed in the pork, is or is not the meat fit for food? We believe it is now well ascertained, that pork is guilty of conveying worms into the body of man only when eaten raw; and that, in fact, unless men eat pork in the uncooked or semi-cooked state, they would never be troubled in their bowels with the loathsome parasite. We give this as an example of the questions which require the scientific consideration of our meat inspectors.

Far be from us the desire in any way to arrest or interfere with the excellent supervision above referred to. In such a case, it is surely better to go too far than not far enough—to err on the safe side. All we wish is that such positions, as that assumed of injury done by unfit food, should not be strained beyond a reasonable point. We wish this in the name of sanitary science, which too often suffers in consequence of the wrong conclusions and actions which are taken in its name.

#### USE OF METHYLATED SPIRIT IN PHARMACY.

ON January 9th, an interesting discussion on the above subject took place at the Pharmaceutical Society. The general feeling was dead against its use; and numerous instances of the abuse of the article were related.

"Mr. Reynolds of Leeds said, in a letter, that the poor were almost entirely supplied with methylated medicines; but the manufacture of sweet spirit of nitre was the chief field for the use of methylated spirit. In Leeds, there was hardly a druggist who did not use it; and there was good evidence to show that 12,000 gallons *per annum* were used in the manufacture of what are called 'Indian spirits.' One chemist alone uses 1000 gallons of sweet spirit of nitre in the production of these compounds. [A sample of one of these compounds was exhibited. It was called 'Cordialised and Highly-concentrated Indian Brandee,' and was evidently a strong spirit, flavoured with sweet nitre, and sweetened—much more of the nature of a liqueur than a medicine. It is retailed in Leeds at threepence per ounce.] Mr. Reynolds stated that by the use of methylated spirit all distinction between pure and impure medicines was broken down.

"Professor Redwood said that the use of methylated spirit in liniments for the army and navy had received the sanction of the Army Medical Board. In many cases, too—as in hospitals and dispensaries—the use had been sanctioned by medical men; and when this was the case, the pharmacist had no choice but to do as he was ordered. He (Professor Redwood) set his face entirely against its use, and, with Professor Graham and Dr. Hoffman had objected to its employment for sweet spirit of nitre. He believed the use of methylated spirit in pharmacy had in some districts opened up an entirely new line of business. In North Wales, he was informed that tincture of assafoetida was now sold on a scale hitherto unknown. Assafoetida used to be taken solid; but now a cheap tincture could be bought, it was preferred in that state, and large carboys of the tincture were sent to some small towns. Great difficulties, he thought, would be experienced in any attempt to stop the use of methylated spirit for medicines.

"The Chairman said the *Pharmacopœia* Committee was opposed to the use of methylated spirit even in liniments, for fear it might stray into other preparations. The opinion of the entire committee, and of the College of Physicians, was against its use."

### HOUSE-WARMING AND VENTILATING.

WE need hardly tell our readers that, with all our boasted hygienic rules and sanitary and social scientific movements, the mode of supply of air to our dwelling-houses, and our methods of heating them, are simply of the roughest and most barbarous. The only individuals who are really scientifically supplied in these respects are those interesting persons who are known of late by the title of "Sir Joshua Jebb's pet lambs." No preparation whatever is made, even in our most luxuriously built modern houses, for the admission of that prime article of life, fresh air. The air finds its way in as it best may—through key-holes, and window-chinks, and doorways, etc. During winter nights, when many fires are burning in our London houses, and large draughts of air are passing up the chimneys, and, consequently, large draughts required to replace them, the air finds its way in as above, and also by the following ways: down some unused chimney; or, and chiefly, from the kitchen and cellar departments; and also not unfrequently from the sewers through untrapped and even trapped openings, and through all rat-holes and crevices leading into them.

The only attempt hitherto made to ventilate our houses has been made at the wrong end; viz., to get rid of the foul air. The only true and perfect ventilation in a town house is that which ensures a supply of fresh air. To ensure a supply of fresh air involves of necessity the removal of the foul air. The condition of our houses is, in this respect, a disgrace to the scientific knowledge of architects. The matter, too, is becoming every day one of greater importance, on account of the increased consumption of gas, and the necessary introduction, therefore, of poisonous gases into them.

The heating of our houses, again, is, as we have

said, most barbarous. Why does not some scientific member of our profession take up and work out practically the subject. By an excellent invention in this way, he would make a grand fortune, and prove himself a benefactor to mankind. It has been said, that an ordinary chimney is the complete solution of the following problem: "To construct an apparatus which, with the greatest possible expenditure, shall produce the least possible effect."

Lastly, at the French Academy, Général Morin read a paper on Ventilation and Heating by means of fireplaces. His experiments were performed in the room of the Director of the Conservatory of Arts. He found, first of all, that 400 cubic *mètres* of air passed every hour through the chimney without any fire. When eight *kilogrammes* of wood were burnt per hour in the same fire-place, from 1200 to 1300 cubic *mètres* passed up the chimney. It resulted from his experiments, that seven-eighths of the heat produced passes up the chimney and is utterly lost as regards the heating of the room, in the fire-place of which the wood is consumed.

### THE MEDICAL COLLEGE AT EPSOM.

WE print, at another page, a further appeal from the Council of the Royal Medical College at Epsom. The appeal is a most honest and legitimate one. We believe that there are still some ten thousand members of our profession who have not yet contributed any pecuniary support to this noble institution—a strange and remarkable fact, when we consider its highly useful and democratic character. But if the immense benefits conferred on the profession by the College are now so universally admitted as to need no illustration here, how comes it, then, that there are so many members of the profession who have hitherto withheld from it their support? We can well understand that there are many of our hard-working brethren with whom the struggle of life is far from an easy one, and with whom even a small pecuniary aid is not rendered without difficulty; but we would remind them that the benefits of this College are especially destined for those members of the profession and their families who have been least favoured by fortune in this battle of life. Those who have most reason to be anxious for the future of their families are just those who, above others, should by precept and example do their best to sustain and invigorate the growth of this paternal institution.

We would especially call attention to one point in this appeal. It is said that there has been a dread with many of their subscriptions being sunk in building. We now learn that those who entertain this idea can, by expressing the wish, have their donations, etc., added to an Endowment Fund. Such a disposition of their money no one can object to. We

sincerely trust, with the Council, that the establishment of this fund may eventually be the means of doing away with that most painful and expensive canvass which is at present necessary to the admission of foundation scholars, by increasing largely the number of scholarships. We would ask our brethren: Is there any more legitimate boon which we as a body can grant to the family of a brother in distress, than that of giving his children an excellent education? Could there be any greater good which an unfortunate or disabled father of a family could wish for his offspring, than that they should receive the benefits of that best of fortunes—a good education? It is to ask the profession at large to further this grand wish of theirs, that the Council now make their present appeal

### THE WEEK.

THE London and Liverpool Insurance Company has, as Mr. Spencer Wells points out, invented a new plan for torturing gratuitous medical advice out of medical men. That ingenious body, instead of applying directly to the private medical man of the person whose life is proposed for assurance, now have the application sent to the medical man by the person proposing himself. This is a distinct putting on of a severe thumb-screw. How can the private medical man refuse the request of his private patient to certify to his condition of health? Mr. Wells having had such an application made to him, answered it to the Company; and then writes the following excellent letter to his patient:—

“January 22, 1863.

“Dear Mr. —,—I received yesterday, from the Liverpool and London Insurance Company, a paper, called a ‘private medical report,’ containing a printed form, which the company have induced you to sign, requesting me to give them a great deal of information respecting your ‘habits, conformation, and general health,’ and informing me that this information is necessary to enable the directors to decide on the proposal of insurance.

“As a friend and patient, it would, of course, give me great pleasure to oblige you in any way, and it would give me far less trouble to fill up the paper sent to me than to write this letter; but there is a principle of great importance to the medical profession involved in this matter, which I will explain to you.

“Some years ago, most insurance companies obliged all who made proposals of insurance to come provided with a medical certificate, and also to submit to an examination by their own medical officer. But, as the companies gained very large profits, other companies were started, and competition had the good effect of lowering the rates of annual payments, and of dividing the whole or part of the profits of the company among the assured. But the tables are still so calculated as not only to insure the company against loss, but to secure so large a profit that a very considerable sum is paid yearly by every office as a commission to agents and others who bring in business; in other words, who introduce persons wishing to insure their lives. It is clear that the profit or loss of any office must depend, in a

great measure, upon a judicious selection of lives; and equally clear that the directors must be guided in their selection by the reports of their own medical officers, and of the medical attendants of the assured. Nearly all the oldest and most respectable offices have gradually been brought to acknowledge that they should pay for the information by which their acceptance or refusal of a risk is decided. A few still hold out, and argue that, as they pay their own medical officer, the assurer should pay his; and this would be fair enough if the engagement were one of mutual obligation; if the assurer were as anxious to insure his life in *one particular company*, as the company is to obtain business. But when there are not only one or ten, but twenty or fifty thoroughly respectable, rich, well-established companies competing for business, and perfectly willing to pay a fair or moderate remuneration for the information they require, no assurer of ordinary intelligence would make his proposal to an office which obliged him either to incur expense, or to ask a favour of his medical man, when he might go to equally good offices who imposed no such condition, but were perfectly ready to pay for the information required.

“I know nothing whatever of the Liverpool and London company; but of all the shabby modes of evading payment for necessary information, and of obliging assurers to obtain this information, that adopted by this company is the shabbiest I ever heard of.

“You, as a lawyer, would very properly resist any attempt of any public company to cut off the proper emoluments of your profession, and will feel that I, as a medical man, by exposing the artifice of this Liverpool and London Company, am only doing for my class what you would do for yours. I am quite ready to furnish you with the names of twenty companies who offer quite as many advantages to assurers as the Liverpool and London can possibly do, and who are not driven to the expedient of begging for gratuitous medical advice.

“Believe me to be, dear Mr. —,—,

“Very truly yours.

“T. SPENCER WELLS.”

His patient, being a man of sense as well as of law, at once sees the injustice of the insurance office's proceeding, and, therefore, writes to the secretary of the aforesaid Company the following note:—

“Dear Sir,—Since I was at your office in Liverpool the other day, I have seen Mr. Spencer Wells, my medical attendant, and having learnt from him that the letter I signed there, and which was addressed to him, is such as to exonerate the London and Liverpool Insurance Company from paying the usual fee, and as he refuses to take any fee from me for his services in this matter, I must decline to insure my life again in your office on such terms, much preferring to insure in an office which properly remunerates medical men for their advice.

“I am, sir, your obedient, etc.”

This is certainly a most excellent example; but can we hope to find many such sensible and reasonable patients as Mr. Wells's has shown himself to be? There may, however, be doubts as to the question who should pay the fee to the medical man, who has an undoubted right to it; and, if the office decline to pay it, we really cannot see why the person whose life is proposed should not do so. The assurance effected is for his benefit; and it is for him, as it seems to us, to settle the question with the office. Nevertheless, Mr. Wells's advice is excellent. Let every medical man do his best to persuade his clients to insure their lives only in those offices who will pay medical men for the information they obtain. We should

then soon have a stop put to their ingenious methods of obtaining the advice gratis.

THE Director of the French Administration General of Public Health has applied to the English Ambassador in Paris, requesting that he would, through the English Government, obtain from the medical men of this country information on the subject of *Tinea Capitis*, as observed in the United Kingdom, and in India, Canada, the Ionian Islands, etc. *Tinea capitis*—a comprehensive term—is, we believe, a much more widely spread disease in France than in England; so much so, in fact, as to become the subject of governmental interference. The Public Administration of Health in France is, it appears, about to organise the treatment of the disease on a more systematic plan. Before doing so, this application to other countries is made for information from those who have had most experience on the subject. A series of questions have been forwarded in schedules, to which answers are sought. The English Government, through Earl Russell, has in consequence applied to the London College of Physicians for its assistance in furthering the wishes of the Frenchman, requesting the College to obtain for him the information sought for. The College have referred the subject to a Committee; and the Committee have recommended that copies of the papers containing the questions be sent to Sir John Liddell, Dr. Gibson, Dr. Farre; to the senior physicians of the naval hospitals of Plymouth and Portsmouth and the military hospital at Chatham; to the medical officers of the Skin Hospital; to the Presidents of the Colleges of Physicians; and to the senior physicians of all the leading hospitals in the country.

MR. SERJEANT WHEELER, Liverpool County Court Judge, does not approve of medical degrees obtained without labour and residence. The learned serjeant thus delivered his judgment on the point last week in his court. Mr. Brown was called to show that the fees charged by a professional brother—Mr. Parker—were too high. Mr. Parker had charged at the rate of 7s. 6d. per visit; whereas he (Mr. Brown) charged only 5s. 6d. per visit, and 6d. for the toll-bar. The serjeant evidently did not approve of this sort of "reducing" evidence.

"Mr. Brown, who was called for the defence, said he was a physician. His Honour asked, if he was a physician, how could he speak to a surgeon's fees? It was intimated to his honour that the witness was a surgeon—that he was a Doctor of St. Andrew's. His Honour: Just as I expected. This is done away with now, is it not? The witness replied that it was not; residence was now required. His Honour said, formerly a person could go one day, get a degree, and walk away dubbed a doctor the next. He had a great objection to this, and preferred degrees obtained by hard work. It was further stated that Mr. Brown was a Member of the College of Surgeons of Edinburgh; and with this statement his Honour expressed his satisfaction."

Our readers will see, by the report of the trial given at another page, that the lawyer was non-suited, notwithstanding Mr. Brown's views of reasonable charges.

WE believe that the Government has made application to the Royal College of Physicians of London, demanding that the College shall receive a lease of its property from the Government. This demand has not a little astonished the College, and will, we have no doubt, be stoutly resisted. The Government asserts that the College is merely leasehold property; that it is held from the Government for a term of one hundred years, forty of which have expired; and now demands that the College shall enter into a lease for its remaining term of sixty years. What has made the kingdom of red-tape thus suddenly rise up and make such a claim upon the College is hard of comprehension. The College, we believe, has no other title to possession beyond the fact of actual and quiet possession, and from what is derived from the general idea of the property having been a gift from the Crown. It has no title-deeds. It has never yet received any lease from the Government, who ought originally to have granted one. The Government, therefore—on, we suppose, the principle of better late than never—is now attempting to repair its former negligence.

MR. TURNER, Dr. A. Ransome, and Mr. Knight, Chairman and Secretaries of the Manchester and Salford Sanitary Association, take exception to a portion of Dr. Buchanan's report, lately alluded to in these pages. In his report Dr. Buchanan observes, that

"Typhus fever (of the true Irish type), which had not prevailed epidemically since the year 1817-8, has in the present year again appeared, and in Preston and Manchester has assumed the epidemic form."

To this the following reply is made.

"We are willing to concede to Dr. Buchanan that twenty fatal cases of the disease did occur during the period of time specified by him. But do twenty cases in a population of nearly half a million, scattered over five months, constitute an epidemic? That no epidemic of typhus fever has prevailed in Manchester since the year 1817-8 is perfectly true, though sporadic cases have during each one of the intervening years never been altogether absent. Nor, if we consider the number and density of the population of Manchester, is there anything very surprising in such an occurrence. If the general standard of the public health is gradually deteriorating in consequence of the too doleful allowance of food meted out to the unemployed, it would be natural to expect that each succeeding month, or, at all events, each succeeding quarter, should exhibit some decided increase both in its general and fever mortality over that which preceded it. What, however, turns out to be the true state of the case? We find that, in the first six months of the year 1862, 31 deaths occurred in Manchester from genuine typhus fever. In the next quarter (and to this and the succeeding one the report more especially refers as those in which the disease took on its epidemic character), the total mortality from fever

is set down at only 78 cases, of which 11 are stated to have been due to typhus; and in that which followed (the last of the year 1862), the numbers given are 118 and 12. We thus see that, during the six months the famine epidemic is said to have prevailed, it carried off only 23 victims; while during the six preceding months it sacrificed no less than 31. We may further observe, that the total number of deaths from all causes in Manchester and Salford during the first six months of the year 1862 was 5,979, while during the last six months it was only 5,409. We have thus the satisfaction of finding that, in spite of the devastating effects likely to be produced by combined epidemics of typhus fever, scarlatina, and whooping-cough, in spite of the wan and haggard looks of the unemployed, in spite of the inadequacy of the food 'to preserve health and strength throughout a lengthened period', 576 fewer persons were conveyed to the cemetery and churchyard during the six months that have just elapsed than during the two quarters that preceded them. These figures speak for themselves."

VIRCHOW appears to be taking a prominent part in the world of politics, as well as of science. The task of drawing up the opposition address to the King of Prussia was, we read, "entrusted to Dr. Virchow, who, it is said, acquitted himself of it with his usual readiness and ability."

"Do you", writes a French journalist, "remark the place that ophthalmology—what a frightful word to write!—takes in our French journals, our book-shops, and on the walls of Paris? All the ophthalmologists of Germany have invaded the town. M. Sichel has made a famous opening there for his compatriots! Since the death of M. Deval, three oculists at least have appeared to take the place: M. de Wecker, M. Liebricht, and M. —, —I forget his name, who have lately arrived, have themselves much spoken of in the journals."

At the celebrated and ancient University of Alcalá, on the 19th of December last, the remains of Francisco Valles were exhumed. He was an illustrious physician of the sixteenth century, the Spanish Hippocrates, deified by his compatriots. Deputations from the Madrid Academy of Medicine, from the Medical Branch of the Army, the royal medical attendants, the press, etc., attended this "pious and imposing ceremony. The memory of the illustrious *savant* was loudly glorified in various discourses, and a banquet terminated this solemn homage rendered to the celebrated commentator of Galen and Hippocrates."

"I have", says M. Chassaignac, "twice practised amputations by caustics. In both cases, the amputation was performed at the middle of the leg, in patients so enfeebled that I dare not amputate in the ordinary way. Both cases were successful. In one case I used the Vienna paste, and in the other a mixture of sulphuric acid and powdered madder. The first of these caustics is not so sure a protection against hæmorrhage as the second, but its action is less painful. In these two cases I left the *bracelet*

fixed on for twelve hours; and five applications were necessary for the complete destruction of the soft parts, the bones being then divided by a chain-saw." It is, we imagine, not necessary for us to describe this last surgical instrument—the bracelet of M. Chassaignac.

The *Gazette Médicale de Lyon* writes thus of advertisements: "The insertion of advertisements in the medical journals is without excuse or justification. Whoever permits it, makes himself voluntarily and knowingly an accomplice in the barefaced falsehoods of the advertising system, and becomes morally responsible for the accidental misfortunes, or the injury done to mortality, which thence result. The *Gazette de Lyon*, we are happy to say, has existed fifteen years, and still exists, thank Heavens, without resorting to this disgrace!"

"I have employed, in the acute articular rheumatism of children, emollient and narcotic applications, large doses of nitrate of potash, leeches, bleeding, and opium, without deriving any real benefits from them. I therefore", says M. Bouchut, "now never resort to these agencies, and only employ sulphate of quinine or veratrine. These two agents are, in fact, actual specifics in acute rheumatism. In a very large majority of cases, they remove the articular inflammation with a rapidity surprising to those who are wont to witness the disease prolonged for weeks and months. Unfortunately, quinine is expensive; and it must be given in large doses, and is then apt to produce unpleasant consequences. Veratrine is equally efficacious, though its physiological action is totally different. Given in doses proper in this disease, it never acts as a purgative. The only action which it has in common with quinine is to reduce the pulse. In two or three days it will bring down the pulse from 120 to 100, 90, and even 60."

There is in London, writes *L'Union Médicale*, a society called *Du Cancer* (Cancer Society), where it is taught that cancer has never been observed in persons affected with an ulceration of the leg. M. Broca, therefore, produces a case at the Surgical Society demonstrative of the contrary.

The Imperial Academy of Medicine has received a communication from Dr. Robert Barnes of St. Thomas's Hospital, claiming the priority in practice of producing premature artificial confinement by means of the uterine dilatation lately extolled by M. Tarnier.

NETLEY HOSPITAL. Arrangements have been made at Chatham for the removal of the invalid *dépôt*, together with the staff at the general hospital, Fort Pitt, to Netley Hospital, which will be ready to be opened in about a month from the present time. The appointment of governor of Netley Hospital has been conferred on Colonel Wilbraham, C.B., governor of the General Hospital, Woolwich.

## ROYAL MEDICAL COLLEGE, EPSOM.

FEW of those who were instrumental in calling into life the Royal Medical College at Epsom, could have anticipated, ten years ago, that, after the lapse of so short a time, it would be enabled to take its place among the first educational institutions of the country. But those who stood by its cradle had a strong confidence in their cause, and in the powerful vitality of their profession. This confidence has not been betrayed. The infancy of the College has not passed away without some rude shocks, which served to test its vigour; the storms have swept over it without impairing its hold upon the profession from which it sprung, and the time has come when the friends of its childhood may hope to see those too rally round it, who, not animated by the same enthusiasm, failed to see in its young germs the same promise of ultimate success.

The time has arrived when the Council need no longer dwell upon mere aspirations, and point to a promise of future reward as an inducement to the profession to support the College at Epsom. They may now speak of a goodly company of boys they have already trained and sent out well prepared for the battle of life; they may point to some who, as in the great public schools of our country, have, through the bounty of benefactors, received gratuitous education; they may draw attention to the weary and invalid of our profession, who in the College have already found the solace and comfort of a home.

But what has been achieved must only be regarded as an earnest of what remains to be done; and as a guarantee that it will be done. The Council are desirous of increasing the number of Foundation Scholarships, and of placing their maintenance upon a footing, independent, at least in part, of the precarious support of annual subscriptions. This should be the noble aim of the entire profession, and if this call be responded to as one concerning each individual member, the realisation cannot be long wanting.

The exhibitors defray their own expenses; but from their payments there is no surplus, nor is there likely to be, for the other purposes of the College. The profession has a right to provide for its own offspring the education it deems fit, and upon its own terms; but it has also an imperative duty to perform to those, who, through the vicissitudes of fortune, have been prevented from securing to themselves, their widows, or their children, such maintenance as their rank and education demand.

Hitherto there has been an objection, on the part of many medical men, to contribute to what is essentially their own institution, from a fear that their money would be sunk in bricks and mortar. The building is now on the point of completion, so that this fear will soon cease to have any foundation; moreover, any donor, or subscriber, may prevent such an application of his contributions absolutely, by intimating a wish that they should be added to the Endowment Fund. When this fund has reached a certain point, it is earnestly to be desired, that the admission of the Foundation Scholars may no longer depend upon the present harassing and expensive method of a general canvass of all the governors, but take place by a competitive examination of the candidates, or some similar proceeding, which may at once render it a reward and a stimulus, while it takes from it that purely eleemosynary character which now surrounds it.

It is this consummation, to the fulfilment of which the Council would venture to call the attention of their

brethren. It is this noble object for which the Council now plead to every registered practitioner; its realisation will be the best evidence that there is such a thing as a strong professional brotherhood, and that the *unity of the medical profession* is more than a dream.

Donations and subscriptions received at Messrs. Goslings and Sharpe's, 19, Fleet Street; and by the Treasurer, John Propert, Esq., 6, New Cavendish Street, W.

## Association Intelligence.

## NOTICE REGARDING NEW MEMBERS.

By desire of the Committee of Council, the General Secretary requests that the Local Secretaries will be good enough to forward to him the names of all New Members who join the Association through the Branches; as otherwise the JOURNAL cannot be sent to them.

PHILIP H. WILLIAMS, M.D., *General Secretary.*

Worcester, November 10th, 1862.

## WEST SOMERSET' BRANCH: CONVERSAZIONE MEETING.

A CONVERSAZIONE meeting of this Branch was held at Clarke's Castle Hotel, Taunton, on Wednesday evening, January 7th; H. ALFORD, Esq., President, in the Chair.

*Communications.* The following communications were made.

1. Excision as a Local Mode of Treatment in Cancer of the Mamma. By H. ALFORD, Esq. He expressed himself as opposed to the operation, and gave a decided opinion, as the result of his experience and observation, that palliative treatment afforded a prospect of longer life than excision.

An animated discussion followed, in which Messrs. Collyns, Randolph, Bush, H. J. Alford, W. Liddon, and Mrs. Pring and Kelly, stated their opinions, cited statistics, and related cases. The prevailing opinion appeared to side with removal, where ulceration had not taken place, and the disease was uncomplicated with glandular affections; and that wherever a tumour presented *doubtful* character, its removal, with or without partial excision of the mammary gland, should be effected.

2. Mr. LIDDON read an interesting case of Aneurismal Tumour of the Femoral Artery, where the usual characteristic symptoms were absent. A formidable operation and its fatal termination were described and commented upon.

3. Mr. LIDDON also showed specimens of Calculi recently removed at the Taunton and Somerset Hospital. One of phosphatic formation, of the size of a small bird's egg, occurred in a boy born and bred in Taunton, and, so far as is known, presented a solitary instance of this disease in a native resident in the town. Until the last few years, cases of stone were almost unknown in this vicinity; and lithotomy was not performed at the Taunton and Somerset Hospital during the first fifty years from its foundation.

4. Mr. RANDOLPH read a remarkable case of Gun-shot Wound, where the charge of shot passed through the arm of a boy eight years old, dividing the brachial artery and median nerve. The limb was saved; and although for a long time it was almost deprived of sensation, and no pulse could be felt at the wrist, after a lapse of two years complete recovery took place, both of nervous power and of circulation through the radial artery.

5. Some interesting wet and dry preparations were exhibited, and short histories of cases given.

*New Member.* Dr. Hamilton Kinglake was elected a member of the Association.

## Progress of Medical Science.

**TREATMENT OF BURNS.** Dr. John Ashhurst, late Senior Resident Surgeon to the Pennsylvania Hospital, in a paper elicited by recent accidents in Philadelphia, observes that a burn is to be looked upon as a constitutional more than a local affection. The first question should be, does the sufferer feel cold; and his pulse and respiration should be carefully observed. Put the patient instantly to bed and cover him with as many blankets as can be obtained; give him quickly a moderate amount of stimulus and a decided anodyne; such as sixty drops of laudanum with an ounce of brandy. The first danger is from shock; of ten patients received into the Pennsylvania Hospital last September from the fire at the Continental Theatre, six died within twenty-four hours, and from shock; some having never reacted, and some after partial reaction sinking again with frightful rapidity. The surgeon should not be in a hurry to dress the patient before attending to constitutional treatment; they will perish from shock if reaction be not obtained. Brandy and opium are the remedies most to be relied on in the treatment of burns. Brandy should be given in the form of milk-punch in preference to being mixed merely with water. The amount of stimulation which is well borne and even necessary in these cases is surprising. For weeks and weeks Dr. Ashhurst has given patients two ounces of milk punch containing one-third brandy, every hour day and night, making a pint of brandy in the twenty-four hours, and this to delicate women and perfectly sober men. Large doses of opium are also required. He generally gives half a grain of the sulphate of morphia every six hours. When the surgeon has seen to the general condition of his burnt patients, and not before, he may properly inquire as to the extent of their injuries. And upon this must in a great degree his prognosis be formed. If half of the surface be involved, no matter how superficial the burn may be, or how good may be the patient's condition, he will almost surely die. Even a burn of one-third of the surface, if it be over the trunk, will almost necessarily prove fatal. And in no case should a recovery be certainly predicted, for burns are not only the most mortal, but the most deceptive injuries the surgeon is called upon to treat. Only a small portion of the surface is to be dressed at once, and it is well to have some systematic mode of procedure. Dr. Ashhurst usually dresses the arms (for they are almost always involved) before any other part, then proceeds to the body, and dresses the face last; this is important, as the dressings cannot be applied as closely to the face as to other parts, and are apt to fall off and require renewal during the changes of position necessary for securing the dressings to the chest or back. The material generally used at the hospital as a primary dressing is the "carron oil," consisting of linseed oil and lime water. This is the most convenient application; its results are, Dr. Ashhurst believes, as good as can be obtained from any other, and in his practice it has been found far more soothing than anything else. The zinc paint is a good dressing, but requires to be frequently renewed, as it becomes dry, and is then very irritating. It is made by incorporating the oxide of zinc with linseed oil, and is applied by means of a brush. He has also painted burns with the solution of lunar caustic, as recommended by Mr. Skey, but has not observed that the sensibility of the parts was diminished by the application. The best method of applying the carron oil is to soak pieces, not more than eight inches square, of patent lint, Canton flannel, or even old linen or cotton goods, in the mixture; and having laid the dressing thus prepared on the parts to be covered, to apply accurately over the whole oiled silk. Should the burn be of the first degree,

or even of the second, provided the vesication were not very extensive, carded cotton might be a good application, as recommended by several surgeons. Even in these cases he should be disposed to cover the parts thoroughly with the carron oil before applying the cotton. Where, however, the parts are more deeply involved, rendering suppuration inevitable, he prefers the dressing by means of patent lint and oiled silk. Although he has not himself used cotton, he is familiar with its application in the hands of others, and he has not observed from its use the great relief from suffering which Dr. Anderson considers one of its principal advantages. If cotton be used, it should be carefully prepared; as met with in commerce it is too apt to contain germs which heat and moisture will develop into maggots. The dressings should be retained in place by means of roller bandages. The face should be covered with a mask prepared in the same way, and having holes cut for the mouth and eyes. It is better to keep the cloth over the face wet by frequent reapplication of the oil; but if this cannot be done it may be covered with oiled silk, secured in this case by adhesive plaster, for a bandage around the head is unnecessarily confining. When the patient is dressed, he almost always expresses himself as feeling much more comfortable. He should be encouraged to make hearty meals. The bowels are very often constipated at first, and should be opened by mild enemata; in the course of a few weeks, however, exhausting diarrhoea is apt to set in. Retention very often, and sometimes suppression of urine, occurs during the first days. This is particularly to be watched for in women, who from modesty are often prevented from making their wants known. The most universal accompaniment of burns and scalds is extreme thirst, and from an injudicious gratification of this desire (in obedience, perhaps, to the vulgar impression that water will put out the fire supposed to be lurking in the system) arises one of the most unfavourable symptoms—viz., sickness of stomach. Dr. Ashhurst allows small pieces of ice to be held in the mouth, or gives small quantities of carbonic acid water; but on no consideration permits more than a mouthful of water to be drunk at once. When the patient has been comfortably dressed and has sufficiently reacted, he may be considered out of immediate danger if the extent of surface burnt is not too great. The third and the eleventh are often spoken of as being critical days, and certainly death is very apt to take place about these periods from hypostatic congestions and effusions upon the lungs or brain, from tetanus or other unavoidable complication. After reaction, if the patient eat and sleep well, if he be quiet and do not vomit everything he swallows, he may be considered as in a very favourable condition. If, on the other hand, he become delirious, his chances of life are very much diminished. The delirium of burns more closely resembles that of *mania à potu* than anything else. The local treatment in this the second stage of burns must depend on the condition of the surface. And it is most important that the sores should be dressed as seldom as possible. The first dressing should not be disturbed till absolutely saturated with the discharges; after this the harm of exposure entailed by a redressing will be less than that caused by the presence of so offensive a mass as the old dressing has become. Dr. Ashhurst has generally found it necessary thus to renew the dressing after two days; and thenceforward every other day it will be usually proper to dress our patients entirely anew. As soon as the slough has come away from any part, he removes the carron oil or whatever dressing has been applied at first, and makes use of simple cerate spread upon patent lint. For this may subsequently be substituted the carbonate of zinc cerate, or the ointment of oxide of zinc, according to the nature of the granulations. In washing burns, after removing the soiled dressings, and previous

to applying the clean, great care must be exercised. The water should be at least at the temperature of the room; better warmer than colder; the room itself should be warm. Care should be taken not to touch the raw surfaces with the sponge used in washing; the granulations are very sensitive and bleed easily. On the other hand, the new skin surrounding the sore should be carefully wiped free from all the discharge which accumulates upon it; for it is important for the patient's health that this skin should exercise as fully as possible its exhalant powers. For the same reason, in applying the dressings no more than the part really sore should be covered, for to cover the new formed skin renders it useless. In the latter stages of burns of the fourth degree and deeper, the sore presents the appearance of an ordinary healthy ulcer; here touching the edges with lunar caustic in substance is very useful in promoting cicatrization. Of course in this the third stage of burns care must be taken, by the use of suitable splints and bandages, to obviate the unsightly contractions which are apt to follow burns affecting more than the mere surface. Burns are the opprobrium of surgery, and will always continue to be so, under whatever treatment; but Dr. Ashurst firmly believes the mortality might be much diminished, could the rules which have been impressed upon his mind by sad experience be made equally clear to every practitioner. (*American Journal of Medical Sciences.*)

**ENORMOUS TUMOUR OF THE SIDE.** At the New York Pathological Society, Dr. Conant presented a large tumour removed from the side of a female, with the following history: Miss A., aged 36, presented herself before the medical class in the University of Vermont, with a large tumour attached to the right side from the median line in front to the median line behind over the crest of the ilium. The tumour was attached by a pedicle about sixteen inches long and four to five deep, and hung as low as the knee of the patient. It was somewhat pear-shaped, with the large extremity down, and was so heavy that the patient had to lift it over herself when she wished to turn in bed. It was estimated that the mass weighed thirty pounds. The patient was just convalescing from measles, and it was thought best to take a week for preparation before attempting an operation for its removal. She was again before the class, when, after having been administered by Professor Stiles, Dr. Conant assisted by Professor Allen and others, commenced the operation by first inserting strong bobbin through the entire pedicle at short distances, tying very tight the different sections as a precaution against hæmorrhage. The ligatures were not all satisfactory as they were constantly giving way during the manipulation of the tumour, so that more than half of them were broken before the operation was completed. The tumour was removed with the *écraseur* of Chassaignac, dividing the pedicle into parts as large as the chain would surround; it required six segments to divide the whole. The hæmorrhage was very slight from the side of the patient, but the veins were numerous and large, and the hæmorrhage from the cut surface of the tumour was so great that they were obliged to be ligatured during the progress of the operation. The time consumed in removing the entire mass was two hours and ten minutes. The surface uncovered was sixty-four square inches. The lips of the wound were brought together by strong sutures, and the patient removed to the ante-room; some hæmorrhage appearing, the wound was opened, and one bleeding vessel secured, after which there was no more trouble. She was removed on a lounge by members of the class to her boarding-house, and carefully watched three days. No unpleasant symptoms arose, dry cloths only were kept applied to the wound, which healed by first intention for about four-fifths of its length. The rest suppurated and healed by

granulation, and the patient returned home the second week after the operation. The patient was very thin, and small in stature, weighing only about one hundred pounds before the operation. The tumour weighed twenty-five, so that one fourth the entire weight was removed. Microscopic examination proved the diagnosis to be correct, and the tumour to be a hypertrophied integumental corium of a fibroma. The patient had numerous small ones in the skin over the body, and proposed to come down each spring and have the largest one removed. (*Phil. Med. Reporter.*)

**EXAMINATION OF THE URINE IN DISEASE.** M. Bouchardat has arranged the necessary agents for such an examination, so as to make the latter easy. The principal agents employed are heat, nitric acid, tannin, lime, and an ioduretted solution of the iodide of potassium. 1. *Heat.* A little above 100°; the urine becoming turbid, will separate albumen in the form of clots or flakes. But it must not be forgotten that every specimen of urine which becomes turbid under the agency of heat is not necessarily albuminous; hence we must employ. 2. *Nitric Acid.* Add some of this acid carefully to the urine. If albumen be present, flakes will be deposited. An excess of acid will dissolve the flakes. Any urine that becomes turbid under the influence of heat, and renders a precipitate under the action of nitric acid, contains, beyond all doubt, albumen. 3. *Tannin.* A solution is made by adding two hundred grammes of water to ten grammes of tannin, and ten grammes of ether are then added to preserve the solution. The action of this reagent cannot be relied upon, since the solution of tannin will produce an abundant precipitate, if soup, rich in gelatine, have been taken shortly before the analysis. 4. *Lime.* This detects admirably the sugar of diabetes. Fifty grammes of urine, and two grammes of lime, being boiled together in an assay-bottle, will give the colour of caramel, more or less dark, according to the quantity of sugar present. The quick-lime is slaked with water, and then introduced into a flask which has a tight cork. If fifty grammes of urine are not coloured when boiled with two grammes of lime, then two grammes more should be added. After the mixture is boiled again, if no colour appear, it is well to test the lime. For this purpose, a half teaspoonful of starch-sugar is poured into the flask. On boiling, if the urine should then be freely coloured, we have proof that the lime had been properly calcined, and that the urine contained no sugar independent of the starch-sugar which had been added. 5. *Ioduretted Solution of Iodide of Potassium.* This is prepared by dissolving one part of iodine and one part of iodide of potassium in fifty parts of water. This solution will communicate a chestnut-brown colour to urine containing sulphate of quinine or any other alkaloid likely to be administered in therapeutics. (*Jour. de Chim. Méd. and Amer. Med. Monthly.*)

**POISONING BY TINCTURE OF VERATRUM VIRIDE.** Dr. G. N. Edwards was summoned, on December 18th, to see a scientific chemist who had taken one drachm of tincture of green hellebore (equal to about twelve grains of the powder). Dr. Edwards found him sitting in the water-closet vomiting into the pan. His features were sunken; the skin cold, and covered with a profuse, clammy sweat; his pulse quite imperceptible. He complained of intense pain about the epigastrium. The vomited matter appeared to consist at first of the food and contents of the stomach; afterwards of glairy mucus. Dr. Edwards gave him immediately about an ounce and a half of pure brandy, which at once checked the vomiting. At this time, he was joined by Mr. Buxton Shillitoe, the patient's usual medical attendant. As the patient had slightly rallied, he was moved into a room a few yards from the water-closet, and laid on the couch in front of the fire. The surface of the body was still

very cold, especially the extremities. The clammy sweat continued, but the pulse could be felt indistinctly, beating, very feebly and irregularly, forty-four in the minute. A dose containing half a drachm of compound spirit of sulphuric ether and a drachm of aromatic spirits of ammonia was given, but immediately rejected by the stomach; but some brandy, given directly afterwards, was retained. A large mustard poultice was applied to the epigastrium, and a large hot-water bottle to the feet. Two or three efforts at retching afterwards took place, and he once or twice vomited food, mucus, and a small quantity of blood. Warmth gradually returned to the surface, and the pulse became somewhat better in volume and power. Brandy was given at short intervals; and, after about an hour, a second dose of ether and ammonia, which was retained. The patient then fell asleep, slept for about a quarter of an hour, and awoke with the expression, "I am all right now," and appeared comparatively well. There was no diarrhoea throughout. He had two or three times a slight return of the symptoms, did not sleep during the night, but was quite easy; and the next morning only felt the discomfort arising from the mustard poultice and the soreness of the muscles caused by the retching. He gave the following account of his feelings during the attack:—"Before taking the dose of the tincture, I had consulted Pereira, and finding Dr. Mead's dose of the tinct. helleb. nig. to be two teaspoonfuls twice a-day, and knowing the green hellebore to be of the same tribe, I considered, in taking one teaspoonful, I was rather under than overdoing it. The drachm of the tincture was taken about half-past four or a quarter to five o'clock p.m., and my stomach soon afterwards whispered that I had admitted a troublesome guest. I went upstairs and sat down, thinking a cup of tea would set all right; but the uneasy constriction of the stomach continuing, with a tendency to sickness, made me retire to the water-closet. The sickness once commencing, soon became alarmingly violent, with the most excruciating pain in the lower part of the stomach, the pain extending to about the size of my hand; the feeling of the seat of the pain was, that all the warm tea, water, etc., that I took to provoke the vomiting, went under the pain, making the constriction more and more violent. Finding the case getting desperate, I sent off for medical aid; the pain continued to increase, and the ejection from the stomach was now glairy mucus with blood, with running from the nose and eyes. The most painful and profuse cold sweating now came on, and the difficulty of breathing became more and more laboured. I could not help wondering at the presence of anything like heat or constriction of the throat; my mind was perfectly calm; and, although I thought it more than probable that I should die, I did not feel alarmed. Hearing and recognising the voice of one of my medical friends is all I recollected for some time afterwards. Immense circles of green colour appeared round the candle, which, as vertigo came on, and I closed my eyes, turned to red. The pain continued excruciatingly at the pit of the stomach, and a slight tendency to cramp existed when my legs were touched. It was some hour or more afterwards when I awoke, and found myself comparatively well. The sting of the mustard I can well recollect, and the horror of being forced to swallow brandy is even now with me. My bowels were not at all acted on. The next morning I took a dose of citrate of magnesia, and, in the evening, a blue pill with colocyth, which relieved my bowels this morning." No authenticated case of poisoning by veratrum viride has been recorded. The full dose of the tincture is eight minims. (*Med. Times and Gazette.*)

LOGWOOD AS A DEODORISING AGENT. A knowledge of its value seems to be more particularly desirable at this time when so many of our soldiers are suffering from sloughing and gunshot wounds. A simple aqueous

solution of extract of logwood applied to such wounds will effectually do away with all offensive odour arising therefrom. In cancerous ulcerations, it is equally valuable; and in cancerous disease of the uterus, that most horrible of all diseases of women, it may be used in the form of injections with complete success in removing the terrible odour which always accompanies such disease. (*Amer. Med. Times.*)

FOREIGN BODY IN THE FOOT FOR FIFTEEN YEARS. A case is related in the *Buffalo Medical and Surgical Journal*, in which a piece of glass, one inch long by about half an inch wide at the base, and terminating in a sharp point, was removed from the foot of a lady, after having been there for fifteen years. The glass was stepped upon, several pieces entering about the head of the metatarsal bone of the great toe; and all but this one were removed at the time. It had passed across the sole, and was extracted about an inch behind the head of the metatarsal bone of the little toe.

## Special Correspondence.

### LIVERPOOL.

[FROM OUR OWN CORRESPONDENT.]

THE usual annual meetings of our three great hospitals have recently taken place; and the following items in the reports seem worthy of notice.

The Royal Infirmary has a surplus of income over expenditure of £722, a much more satisfactory state of account than has often been presented at the close of the financial year. From the report of this institution, it appears that a handsome and commodious building has been erected, and is on the eve of completion, as a Nurses' Home, intended for the residence of females who are to receive instruction in the wards of the infirmary. It is also in contemplation to erect additional wards to be set apart for the reception of females suffering from uterine disease; a philanthropic and sympathising lady having placed at the disposal of the trustees, for this purpose, the munificent sum of £10,000. The managing committee have done a gracious deed in voting a donation of £200 to Mr. Parker, the late governor of the lunatic asylum, which constitutes a part of the establishment, who retires from ill-health after a servitude of eighteen years. It should be stated that, contrary to the usual arrangement in lunatic asylums, the late governor was not a medical man; but the vacancy is now filled by Dr. Stark, late medical officer at the County Asylum at Lancaster, and it is probable that for the future the appointment will always be in the hands of a professional man.

The Northern Hospital is not in so fortunate a position as to funds; the annual income falling short of the expenditure to the serious extent of £1500. This appears to have arisen from a considerable decrease in the number of subscriptions, as well as of donations and bequests; and is, probably, in some measure, the result of the stagnation in business consequent upon the cotton famine. There is good reason, therefore, to hope, in the words of the Mayor, who presided on the occasion, that "the cloud which has now so long been hovering over us will soon disappear, and, as the new year

rolls on, business may regain its former activity, when the hearts and purse-strings of the people will cheerfully yield a liberal response to the appeal on behalf of this excellent institution."

In the proceedings of the Southern Hospital, it was intimated that in the course of the present year the office of physician to the institution will become vacant by the retirement of Dr. Cameron, whose period of service will expire, in accordance with the tenure of office, which, at this hospital as well as at the Northern, is limited to a definite number of years.

Our parochial authorities are discussing the question as to whether it is requisite or desirable to extend the existing accommodation for the reception of fever patients by the erection of a larger fever hospital in a suitable locality, to supersede the present building, which is thought to be too small, and its present situation, within the precincts of the workhouse, undesirable. From the report of the medical officers, Dr. Gee and Mr. Fletcher, it appears that the present building is well ventilated, and sufficiently isolated from the adjacent buildings; and, in their experience, fever has not been communicated therefrom to the other parts of the workhouse. The number of beds (which is ninety-six) has for the past eight years been sufficient to accommodate all the pauper fever cases that have required admission; but if the number of patients now in the wards should prove to be the average, more extended accommodation will be necessary. As public bodies are proverbially slow in action, it is probable that official delay will afford an opportunity of determining whether the present high rate of fever in the town is only temporary, and thus enable the ratepayers to satisfy themselves as to the necessity of this additional burden upon their funds, before undertaking a work which, however desirable, would doubtless involve a considerable addition to the present expenditure.

The coroner's court has lately afforded another example of the prevalent evils of counter-practice by druggists, or, perhaps, in the present instance, of the incautious manner in which people often venture to become their own doctors. A father, finding that his infant, three weeks old, was very cross, went to a druggist's shop and purchased a pennyworth of syrup of poppies, and administered two doses of half a teaspoonful each to the child, who died the next day. A surgeon had been called in, who found the child narcotised; and upon his evidence, a verdict was returned of *Chance Medley*, accompanied with the opinion that the druggist had been much to blame in not having asked what the syrup was for, and stated the quantity to be taken.

Considerable activity and excitement are now prevailing in our medical world, in the prospect of three vacant appointments about to be filled up.

In consequence of the death of Mr. James Cooper, who held for many years the post of surgeon to the borough police force, the watch committee of the Town Council have determined to divide the office into two, one for the north and one for the south division of the borough, at a salary of one hundred guineas each; the duties being to examine all recruits before joining the force, and attendance upon men injured when on duty—

all other sickness occurring to the officers being already provided for by a benefit society of their own.

The select vestry of the parish have also a little patronage to bestow, owing to the resignation of Dr. Ayrton, one of the district medical officers. The remuneration and duties of this appointment have been fully detailed in one of my recent letters. As it is just possible that the bare announcement in your widely-circulated columns of these splendid openings might cause an influx of medical adventurers from distant parts, it may be well to add that although, of course, the field is open to all, and although the appointments, up to the time I write, have not been advertised, an active canvass has already been completed by the candidates, whose name is legion, and some of whom possess such local standing and influence as would probably reduce the chances of a stranger to a minimum. It is reported, but I cannot vouch for its accuracy, that there are no fewer than seventy applicants for the police appointments. With regard to the parochial district, I have authority for stating that there are already twenty-four candidates in the field. What a commentary upon the position and prospects of our overstocked profession!

## Reports of Societies.

### OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, JANUARY 7TH, 1863.

W. TYLER SMITH, M.D., President, in the Chair.

*Beef-Tea.* A preparation of Concentrated Beef-Tea was exhibited to the Society by Mr. BUCKLE, Culinary Chemist, of North Place, Gray's-inn Lane, convenient for administration in cases where expeditious employment of nutritive material is required.

ON VAGINAL LITHOTOMY. BY J. H. AVELING, M.D., SHEFFIELD.

The paper commenced by reciting the particulars of thirty-five cases in which this operation had been performed—twelve British, and twenty-two foreign. The author also gave another case, in which he divided the vesico-vaginal septum, and extracted a small rough stone. The wound was brought together with silver wire sutures. Gilt beads were passed over the ends of these, and run down to the lips of the wound. These were kept in position by a perforated shot, also passed over the ends of the sutures, and tightened upon them by a pair of forceps. He proposes in future to use a coil, made by winding a piece of the suture wire round a pin, instead of the beads. The wound healed in a week, and the patient returned to her home in a fortnight.

Mr. SPENCER WELLS congratulated Dr. Aveling upon the successful result of his interesting case. But he had begun to doubt whether the success which had followed the operation for the cure of vesico-vaginal fistula of late years was so much due to the use of wire sutures as to the improvements which Dr. Sims had originated in the mode of bringing the fistula into view, accurately paring the edges, and bringing them into perfect apposition. After many comparative trials on different parts of the same wound with wires of silver, iron, lead, platinum, and aluminium, and with fine catgut, horse-hair, telegraph wire, india-rubber thread, and the fine strong silk known as "Chinese twist," he had become convinced that wires offered no advantage over silk, while silk offered many advantages over every other material

used for sutures. In a recent case he had closed a vesico-vaginal fistula by five silk sutures, and perfect union resulted, although no catheter was used. The supposed necessity for the use of the catheter after closing vaginal fistula, was another error which time was correcting. The urine is by no means so irritating a fluid as some believe. With regard to stone in the bladder during labour being a cause of vesico-vaginal fistula, he had once removed in the Samaritan Hospital a large stone through a fistula before closing it; but it was very questionable whether it could often be necessary to remove a calculus through the vagina when no fistula existed, or to run the risk of making a fistula to remove a stone. Lithotomy was very easily performed in women; and large fragments of stone passed readily through the short female urethra, so that no form of lithotomy could often be called for. Where, from some exceptional condition of bladder or stone, lithotomy was inappropriate, vaginal lithotomy might become a valuable operation; but experience was still wanting to show that it was better than, or as good as, the lateral operation so successfully practised by Dr. Buchanan of Glasgow.

### TREATMENT OF SMALL-POX BY SARRACENIA PURPUREA.

LETTER FROM CHARLES J. RENSHAW, M.D.

SIR,—As there is some difference of opinion with regard to the efficacy of *sarracenia purpurea* in small-pox, I think the accompanying cases may be worthy of publication.

CASE I. E. A., aged 30, vaccinated when an infant, of good general health, complained on October 31st of feeling unwell, and thought she had taken cold. Nov. 4th. I was called to see the patient, and found her in a state of partial stupor, with severe headache, pain in the back, and feeling of nausea. The urine was high coloured and scanty; bowels costive; tongue dry, dark in the centre, and furred at the edges; pulse 130, hard. I prescribed a purgative to be taken immediately, and a saline every four hours. Nov. 5th, 10 A.M. The patient was unable to speak. The symptoms were no better. The arms, face, and parts of the body were covered with eruption. 8 P.M. She appeared easier; the eruption was spreading. Nov. 6th. Vesicles were forming. She appeared generally a little better. I gave her a decoction of *sarracenia purpurea*. Nov. 7th. The patient was better in every way. The stupor was entirely gone; the head was much easier; she had no nausea; the tongue was moist; pulse 100, soft. The urine was not so high coloured, nor so scanty. The eruption was rapidly assuming the pustular form. Nov. 8th. During the night, the pustules had filled and died; they were like scales elevated from the cuticle; not one had scabbed. The patient felt well, but weak. Nov. 9th. The patient continued to improve. The scabs began to drop off, leaving no pitting.

CASE II. T. A., aged 10, had been vaccinated when an infant. He began to complain November 3rd. On the 6th, the eruption made its appearance, with the usual symptoms of small-pox. I prescribed decoction of *sarracenia purpurea*. In two days the pustules fully formed and died; not one scabbed nor pitted, but all fell off in scales. The patient rapidly recovered.

CASE III. J. R., aged 21, who had never been vaccinated, began to feel poorly October 30th. On Nov. 1st, the usual symptoms of small-pox set in. Nov. 2nd. The eruption began to appear. Nov. 3rd. I prescribed the same decoction. After the first dose, he felt relief. The course of the eruption was completed in forty

hours, and the pustules appeared as scales. One only had burst, and that the patient had scratched; they all fell off without leaving a single instance of pitting.

I have used this decoction in two other cases, with similar effects.

The effect of the *sarracenia purpurea* in these cases seems to agree with the account of its properties given by Mr. H. Chalmers Miles in the *Lancet* for Oct. 18th. Though all the cases were of the simple variety, yet even in these cases the pustules generally burst, scab, and occasionally pit; and the disease is generally of much longer continuance. In each instance, the patient felt better after taking the first dose. By the third day, the pustules had formed and died. Only one had formed a scab, and that from accident. There was no secondary fever nor pitting in any of the cases.

The remedy is, I think, worthy of more general use.

I am, etc., C. J. RENSHAW.

Altrincham, December 1862.

### THE SULPHITES IN DIPHTHERIA.

LETTER FROM JOHN LYELL, M.D.

SIR.—In the March number (1862) of the *BRITISH MEDICAL JOURNAL*, the experiments of Dr. Polli of Milan on the action of sulphurous acid as an antiferment in blood-poison were briefly noticed. From that notice I have been led to the use of this as a therapeutic agent in diphtheria, so evidently toxæmic in its nature; and I beg here to call the attention of the profession to the use of it in that disease. Diphtheria has been prevalent here as an epidemic, and an opportunity thus given for testing the value of this and other curative means. From Bretonneau downwards, these have been acknowledged to be exceedingly unsatisfactory and inefficient; and on its first outbreak here, every means employed seemed to be utterly powerless, whether these were local or general. After a time, I began to use sulphite of soda in half-drachm doses, every six hours or every four hours where the case seemed more urgent. As the improvement following the use of this remedy has been apparently very marked, I have written this brief note in order that its value may be tested where diphtheria at present prevails. The prescription I have been using is the following: sulphite of soda ʒss; water ʒiv. A tablespoonful (ʒss) to be taken every four or six hours.

As a topical application, I use the insufflation of a few grains of calomel to the exudation on the fauces through a gutta-percha tube, together with the inunction of simple camphorated or iodised camphorated ointment. I have no faith in the application of nitrate of silver or other caustics to the parts. By pitting one side of the throat against another, I have found the cauterised side more tardy in getting well than the other. The permanganates and other topical applications I have used, but I cannot say with benefit. My object, however, in now writing is to get the sulphites tested as depurants and antiferments in this terrible toxæmic malady.

I am, etc., JOHN LYELL.

Newburgh, Fifeshire, January 13th, 1863.

EARLSWOOD ASYLUM. One of the most useful of our charitable institutions is the Asylum for Idiots at Earlswood. What is done there, in the way of reviving the flickering light of reason, can only be understood by those who have visited the asylum. Yesterday the annual New Year's festivities took place. There was a distribution of prizes to successful pupils in the schools, a dinner to the inmates, and subsequently a series of amateur dramatic performances. All passed off in a most satisfactory manner.

## Medical News.

**ROYAL COLLEGE OF SURGEONS.** The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners, on Jan. 20th:—

Baker, Thomas Franklin, Doncaster  
Bobart, William Matthews, Ashby-de-la-Zouch  
Bracey, William Arthur, Birmingham  
Brown, Isaac Baker, Connaught Square  
Chaudler, Edward, Chester Place, Kennington  
Cross, Arthur John Graham, New Street, Spring Gardens  
Elliot, George Hurlstone, Chichester  
Ellis, Edward, Fitzroy Street  
Fry, J. hu Blount, Edgbaston, near Birmingham  
Lattey, James, Upper Phillimore Gardens  
Megget, Archibald, Scarborough  
Mottershead, John, Macclesfield  
Randell, Edward Benjamin, Carshalton  
Roberts, James Dixon, Shipley, near Leeds  
Saville, John James, Sunderland  
Simpson, Philip John, Gower Street  
Smallhorn, Thomas, Dublin  
Spurway, Charles, Tiverton, Devon  
Willes, Joseph, Brighton  
Williams, John Wilkins, Paddington  
Wilson, John, Musselburgh  
Wood, Eltham, Toronto

**NAVAL SURGEONS.** The following gentlemen passed their examinations for Naval Surgeons at a meeting of the Court of Examiners, on January 20th:—

Allison, Thomas Dunlop, M.D. Glasgow, M.R.C.S. Eng.: diploma of membership dated June 25, 1858  
Hughes, Thomas Williams: June 13, 1856  
Keelan, Patrick, of H.M.S. *Neptune*, M.R.C.S. Irel.: Nov. 4, 1855  
Roche, William (B.), of the Royal Naval Hospital, Plymouth: May 24, 1855

**Admitted Members on January 21st:—**

Agassiz, Alfred, Bradfield, Essex  
Brittain, Thomas Lewis (M.D. Edin.), Chester  
Bruce, James, Islington  
Buckmaster, Charles Addams, Piccadilly  
Cartmel, Henry, Manchester  
Clarkson, Frederick Robert, Leeds  
Craister, Thomas Lawson, Leeds  
Davies, John, Coleshill, Warwickshire  
Hay, Robert, Belfast  
Leigh, Thomas, Chiswick  
Meeres, Albert, Thame, Oxford  
Miskin, George Albert, York Road, Lambeth  
Nest am, Thomas Cargill, Newcastle  
Pattinson, Henry Albert, Penrith, Cumberland  
Rains, Samuel, Manchester  
Reddrop, John, Tiverton, Devon  
Richards, Henry Ebenezer, Sloane Street  
Row, William, Clapham Road  
Sargent, George Pearce, Camberwell  
Stone, Robert Sidney, Bath  
Thorne, Richard Thorne, Leamington  
Turner, Arthur Newman, Bernouisey Square  
Wadsworth, Alfred, Leeds  
Walker, Samuel Edward, Warwick  
Welby, William Montague Hall, Newark, Notts  
Wright, George Vint, Edinburgh

**Admitted Members on January 22nd:—**

Arnott, John Lovell, Cheltenham  
Butlin, Charles Henry, Camborne, Cornwall  
Canny, Denis Joseph, Dublin  
Cooper, William, Beaumont Street, Cavendish Square  
Daniel, William Clement, Kennington  
De Leon, Jacob, Jamaica  
Dick, Thomas Thomson, Ayr  
Farwell, Arthur John, Chipping Norton  
Gregson, George, Harley Street  
Mapleson, Horley Thomas, Westbourne Place  
Meadows, Robert, Ipswich  
Smith, George, Hampstead Road  
Smith, Philip Henry Pye, Hackney  
Smith, William Frank, Nottingham  
Thornburn, John Edward, Cockermouth

**APOTHECARIES' HALL.** On January 22nd, the following Licentiates were admitted:—

Holbs, Henry Addison, Croydon  
Walker, George Edward, Wigan, Lancashire

## APPOINTMENTS.

\*DE MORGAN, Campbell, Esq., F.R.S., appointed Consulting Surgeon to the East Grinstead Dispensary, in the room of M. Henry, Esq.  
EDWARDS, Morgan J., M.D., appointed House-Surgeon to the Glamorganshire and Monmouthshire Infirmary, in the room of F. B. Hutchinson, L.R.C.P. Ed.  
EVANS, Caleb, Esq., appointed Surgeon to the Birkenhead Borough Hospital.  
GAIRDNER, William T., M.D., appointed Medical Officer of Health for Glasgow.  
GRADHAM, George W., Esq., appointed Senior Assistant Medical Officer to the Surrey County Asylum.  
HARVEY, Alexander, M.D., appointed Surgeon to the Aberdeen Ophthalmic Institution, in the room of the late J. Cadenhead, M.D.  
LAPRAIK, Thomas, M.D., elected Surgeon to the Glasgow Asylum for the Blind.  
SELWOOD, Henry C., M.D., elected House-Surgeon to the Birkenhead Borough Hospital, in the room of C. Evans, Esq.  
STAMPER, James F., M.D., appointed House-Surgeon to the Tunbridge Wells Infirmary, in the room of R. Hicks, Esq.  
WARD, Charles P., Esq., elected Visiting Surgeon to the Royal South London Dispensary.

## ARMY.

To be Staff-Assistant-Surgeon:—

JACKSON, R. W., from half-pay.

## ROYAL NAVY.

BRIEN, Charles R., Esq.  
DAVIES, Edward, Esq.  
FULLER, Charles H., Esq.  
LARDNER, Jason, Esq.  
LIDDELL, Henry, Esq.  
LAW, Ernest, M.D., Acting Assistant-Surgeon, to the *Buzzard*.  
RARIE, John, Esq., Surgeon, to the *Buzzard*.

To be Deputy Inspectors of Hospitals and Fleets, on the Retired List.

**VOLUNTEERS.** (A.V.—Artillery Volunteers; R.V.—Rifle Volunteers):—

PLYLE, T. T., M.D., to be Assistant-Surgeon 3rd Durham R.V.  
WALLACE, S., M.D., to be Assistant-Surgeon 1st Administrative Brigade Glamorganshire A.V.

## BIRTHS.

BARKER. On January 20th, at Bedford, the wife of \*T. Herbert Barker, M.D., of a daughter.  
FLOWER. On January 28th, at 39, Lincoln's Inn Fields, the wife of W. H. Flower, Esq., of a daughter.  
SWEETING. On November 3rd, 1862, the wife of the Rev. G. Sweeting, Perth, West Australia, and eldest daughter of \*F. Page, M.D., Southsea, of a son.

## DEATHS.

BOULT, Edmund, Esq., Surgeon, at Bath, aged 48, on January 24.  
CATLETT. On September 28th, 1862, at Sydney, New South Wales, Emily Marsh, wife of William Catlett, M.D.  
CRIGAN, the Reverend Alexander, M.D., vicar of Skipworth and Riccall, Yorkshire, at Sidmouth, aged 82, on January 25.  
FOWKE, Frederic, Esq., Ryde, Isle of Wight, aged 57, on January 24th; and on the same day, aged 59, Anne Waiuwright, his wife.  
HANNAH. On January 22nd, James W., eldest son of James Lee Hannah, M.D., Brighton.  
HOLDEN. On January 23rd, at 54, Gower Street, Frances, wife of Luther Holden, Esq., Surgeon.  
HUTCHINSON. On January 16th, at Ramsgate, aged 8, Montier Vaux, fourth son of T. Cayley Hutchinson, Esq., Surgeon-Major, Indian Army.  
MENZIES. On January 26th, at 23, Westbourne Park Road, aged 6 years, Agnes, only daughter of Duncan Menzies, M.R.C.P.L., Deputy Inspector-General of Army Hospitals.  
RANSAY, David, M.D., R.N., late H.M.S. *Gorgon*, at the Royal Naval Hospital, Simon's Bay, on December 16th, 1862.  
SMITH, George T., Esq., Surgeon, at Leamington, on January 19.  
WILLIAMS. On October 30th, 1862, at Melbourne, aged 61, Charlotte, widow of John M. Williams, Esq., Surgeon, Kennington.

**THE LECTURES AT THE COLLEGE OF PHYSICIANS.** Dr. Risdon Bennett, Dr. T. K. Chambers, and Dr. Pavy will this year deliver the Croonian, Lumsian, and the Gulstonian Lectures, at the College of Physicians.

**POPULATION OF VICTORIA.** Although Victoria has had to meet the temptation of the New Zealand gold-fields, the population continues to increase. The Registrar-General has issued his return for the quarter ending at Michaelmas last, and states the number of the people at that date to be 549,901, of whom 322,984 were males, and 226,917 females.

**A SURGEON COMMITTED FOR PERJURY.** Mr. Evan Thomas, a surgeon, one of the district medical officers of the Manchester Board of Guardians, has been committed to take his trial for perjury. The strange circumstances connected with the cause of his committal have been doubtless read by all our readers. The real facts of the case will probably be more fully elucidated at the next Liverpool assizes. Mr. Thomas is in the meantime liberated on bail.

**MEDICAL SOCIETY OF LONDON.** A course of three Lettsomian Lectures on the Surgical Diseases of Children, by Mr. Thomas Bryant, F.R.C.S., Assistant-Surgeon to Guy's Hospital, will be delivered February 9th, 16th, and 23rd. Lecture I will be "On the Differences between the Physiological and Pathological Processes in Children and in Adults; and on some Congenital Deformities, as Harelip and Malformations of the Rectum." Lecture II, "On the Differences between Surgical Diseases of the Nervous, Respiratory, Circulatory, Digestive, and Urino-genital Systems of the Child and the Adult." Lecture III, "On the Diseases of the Osseous System, and on Tumours, etc."

**MAN AND THE MONKEY.** A London correspondent says: "A valuable contribution to the science of anthropology is about to be given to the world by Professor Huxley, in a volume entitled *Man and the Ape*, or some such title, discussing, in a very complete form, the question at issue between Mr. Huxley, and the anatomists who agree with him, and Professor Owen. Meanwhile, by way of contributing further practical illustrations to the subject, Captain Burton has come to an agreement with M. du Chaillu to join the latter in a gorilla-hunting campaign in the Gaboon. The preliminaries were signed at a leave-taking dinner which M. du Chaillu gave his friends the other day, before starting for New York, where he has matters of business to arrange before facing again the Gaboon and the gorillas."

**THE STATE OF HEALTH OF MANCHESTER.** Although it is an undoubted fact that the calls made during the latter portion of the past year upon the diff rent hospitals and public medical charities proved unusually numerous, we have nevertheless satisfied ourselves that this circumstance is to be explained rather by the inability of the operatives to pay for medical assistance, than by any general increase of sickness; and we can conscientiously assert that we never remember the public health of Manchester and Salford, during the winter months, to be in a more satisfactory state than it is at the present time. Nor have we noticed, during the frequent occasions on which we had been brought into contact with the unemployed operatives, any of that "loss of strength, colour, and flesh," which is stated in the report to have been observed in the majority of the cotton districts. (*Report by Messrs. Turner and Ramsome.*)

**ROYAL COLLEGE OF SURGEONS.** The subject for the Collegial Triennial Anatomical Prize of fifty guineas is, "The Structural Anatomy and Physiology of the Lymphatic Vessels and Glands (the Anatomical Distribution not being required); the Communications (if any) between the Lymphatics and the Blood-vessels to be demonstrated; and the Influence (if any) which the Lymphatic Vessels or Glands exercise on the Fluid they transmit, to be elucidated. The dissertation to be illustrated by preparations and drawings." The essays on this subject must be sent in on or before Christmas Day 1864.—The subjects for the Jacksonian Prizes of twenty guineas, for the present year 1863, are: "The Pathology and Treatment of Diseases of the Larynx; the diagnostic indications to include the appearances as seen in the living person. The dissertation to be illustrated by drawings and preparations." And "The Normal and Pathological Anatomy of the various Syno-

vial Bursæ connected with the Muscles and Tendons of the Upper Extremity, and the Treatment of their Diseases. The dissertation to be illustrated by preparations and drawings." The essays on these subjects must be sent in on or before Christmas Day next. The terms and conditions may be known on application to the Secretary.

**COLNEY HATCH ASYLUM.** The annual winter entertainment to the patients, now numbering nearly 1,900, of this institution took place on the 20th inst., before a large assemblage of the county magistrates, their friends, and others interested in the subject of insanity. At four o'clock, about 250 men and 350 women assembled in the large hall, which was very brilliantly lighted, and decorated with flags, Chinese lamps, and evergreens. The amusements commenced with the tricks of a professed conjurer engaged for the occasion, who was followed by Mr. Punch, Mrs. Judy, and the faithful dog Toby. After this, at six o'clock, the patients retired to their wards, where they were regaled with plumcake, oranges, spiced ale, and lemonade, in which those who were unable to be present in the hall participated. At seven o'clock the hall was again filled with the busy and happy population, when dancing commenced, and was kept up until nearly ten, when the National Anthem closed the proceedings. We are happy to record that not a single casualty or unpleasantness occurred to mar the pleasure of the evening. During the time the patients were at supper, the magistrates entertained the company at a very sumptuous repast. It is right to add that all joined in dancing and the various efforts made to amuse the patients; and it was universally admitted that the Colney Hatch winter fête of 1863 is entitled to rank as the most brilliant and successful in the asylum's history.

**ACTION FOR THE RECOVERY OF MEDICAL FEES.** In the Liverpool County Court, Mr. Edward Parker, surgeon, of Kirkdale, claimed from Mr. Chilton, solicitor, the sum of £8:8, balance of an account due for professional services. The evidence adduced by the plaintiff was to the effect that from March to July 1861 he professionally attended the family of the defendant. On the 26th of June, the plaintiff was requested by Mr. Chilton to send in his bill, which was accordingly done; and in this bill he charged the sum of 10s. 6d. for a visit at night, and 7s. 6d. each for all other visits. The bill amounted to £6:10:6. Subsequent to the delivery of that bill, plaintiff made several visits, for which he charged 7s. 6d. each. For these latter services he sent in a bill amounting to £1:7:6. On calling for payment, he saw Mrs. Chilton, who informed him that the bill was disputed by her husband, on the ground that more visits were charged for than had been made, and the plaintiff agreed to send in a bill of particulars to Mr. Chilton. Mr. M'Oubrey said Mrs. Chilton would not be called as a witness. His Honour remarked, that it appeared to him the only question to be decided was whether the plaintiff's charges were proper. It was a very serious imputation upon a medical practitioner in Liverpool—who had undoubtedly, as far as had been seen in the witness-box, given his evidence with the greatest possible regard to truth—to turn round upon him in this way. The case had been adjourned to allow Mrs. Chilton to attend; but he had so good an opinion of her sex, that he should have been very sorry to have seen her go into the box to disparage the medical gentleman who had attended her. Mr. J. P. Harris, surgeon, of Rodney Street, deposed that the charges made by the plaintiff were fair and reasonable. Mr. Brown, who was called for the defence, deposed that he had professionally attended Mrs. Chilton; and his charge for ordinary visits was 5s. 6d. each, and 6d. for the toll-bar. This was the whole of the evidence; and his Honour gave a verdict for the amount claimed, in addition to £2:15 paid into court.

## OPERATION DAYS AT THE HOSPITALS.

MONDAY.....Royal Free, 2 P.M.—Metropolitan Free, 2 P.M.—St. Mark's for Fistula and other Diseases of the Rectum, 1.15 P.M.—Samaritan, 2.30 P.M.—Lock, Clinical Demonstration and Operations, 1 P.M.

TUESDAY.... Guy's, 1½ P.M.—Westminster, 2 P.M.

WEDNESDAY... St. Mary's, 1 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.

THURSDAY.... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—London, 1.30 P.M.—Great Northern, 2 P.M.—London Surgical Home, 2 P.M.—Royal Orthopaedic, 2 P.M.

FRIDAY..... Westminster Ophthalmic, 1.30 P.M.

SATURDAY.... St. Thomas's, 1 P.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY. Medical Society of London, 8.30 P.M. Clinical Discussion. Dr. Cockle, "On the Conditions of the Aorta Simulating Aortic Insufficiency"; Mr. Sreeter, "Disease of the Brain by Extension from the Ear"; Dr. Greenhalgh, "New Metrotome"; Dr. Richardson, "Nitrate of Amylene"; Communications from Drs. Gibb and Thudichum; Mr. Baker Brown and others.—Epidemiological Society, 8 P.M. Mr. Thomas Hunt, "On Certain Epidemic Forms of Cutaneous Disease observed in Schools, Workhouses, and Factories."—Entomological.

TUESDAY. Pathological.—Photographic (Anniversary).—Ethnological.

WEDNESDAY. Obstetrical Society of London, 8 P.M. Mr. Baker Brown, "On Vesico-Vaginal Fistula: Results of Fifty-five Operations at the London Surgical Home"; Dr. Shortt, "On the Medical History of Woman in India."—Society of Arts.—Geological.

THURSDAY. Royal.—Audiqurian.—Linnæan.—Chemical.—Harveian.

FRIDAY. Western Medical and Surgical Society of London, 8 P.M. Practical Evening for the Narration of Cases and the Exhibition of Specimens.—Royal Institution.—Archæological Institute.

SATURDAY. Army Medical and Surgical.

## TO CORRESPONDENTS.

\* \* All letters and communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen St., Lincoln's Inn Fields, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

L.R.C.P. AND M.D.—SIR: I believe I am correct in stating, in reference to your observations upon Dr. Styrap's communication, that the new Charter recently granted to the Royal College of Physicians of Edinburgh, secures, in general terms, to its Licentiates, any privileges which might appertain to the Licentiates of any other College of Physicians within the United Kingdom. Consequently, the Licentiates of the Edinburgh College have now the same claim to the doctorate as that possessed by the Licentiates of the Dublin College—be this what it may.

January 1863.

I am, etc., L.R.C.P.ED.

THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—SIR: I am astonished to find in the BRITISH MEDICAL JOURNAL of January 17th, the question as to the power of the King and Queen's College of Physicians in Ireland to confer the title of M.D. revived, after the decision on this point by the Court of Queen's Bench, Ireland, when this question of the College was tried by their Lieutenant, Mr. Barker, on a *mandamus* to compel his name to be restored as a Licentiate and as a Medical Doctor, by the Medical Registrar of Ireland; the M.D. importing Medical Doctor, having been erased, and the letters struck out, under the authority of the General Council.

Subjoined are the dates of the opinion of the Attorney-General for Ireland, and the subsequent decision of the Court of Queen's Bench. It is needless to say which is the higher authority, or to point out that if the power to confer the title or degree had existed in the Charter, they (the College) would have only been too glad of this opportunity of proving it, by the simple production of their Charter.

I am, etc., Δ

January 19th, 1863.

Opinion of Attorney-General, Ireland. "I think the Licentiates and Fellows, as such, of the King and Queen's College of Physicians are entitled to the degree and title of Doctor in Medicine, and to use the letters M.D. after their names."

" (Signed), R. DEASY.

Abstract of Decision, Court of Queen's Bench, Ireland, March 10th, 1861. "Their (the Corporate Bodies) licence entitled the party to be called a Licentiate of the particular Corporation; and in the schedule there is a marked distinction between a Doctor of Physic, which is a degree, and a Licentiate, because the medical corporations cannot grant a degree, entitling the party to be entered under their diploma as a Doctor of Medicine, but they may give a licence, thus creating the party a Licentiate, as in the present case. The distinction is taken in the most marked manner.... "The applicant, Mr. James Barker, jun., had a diploma from the College of Physicians (K. & Q.C.P.L.), but that was not any of the qualifications mentioned in the schedule entitling him to be registered as a Doctor of Medicine," etc. Counsel for the prosecution, Mr. Brewster, Q.C., and Mr. W. Smith. For the defendant, Mr. J. E. Walsh, Q.C., and Mr. Jellett.

S. R.—We believe it is quite true, that the carriages, neither of the medical men nor of the patients, are allowed to spoil the unity of the surface of the gravel roads in the Surrey Gardens. All must descend at the gate, and thence (if they can) walk on foot to the door of the temporary hospital. Our correspondent asks, Who is responsible for this absurd and childish act of authority? The question is difficult to answer, because the ruling power of St. Thomas's Hospital is not distinctly set forth before the public. We have, however, always understood that there is one prominent potentate, called the Treasurer, who is the dictator and absolute ruler of the roast for the time being. He is, therefore, we suppose, the issuer of the order in question, and responsible for the folly of it. Some of our readers will ask: Is this a specimen of the acts of the genius which presides generally over the welfare of the notorious St. Thomas?

COMMUNICATIONS have been received from:—Dr. J. BIRBECK NEVINS; THE HON. SECRETARIES OF THE WESTERN MEDICAL AND SURGICAL SOCIETY OF LONDON; Mr. T. M. STONE; Dr. HYDE SALTER; THE HONORARY SECRETARIES OF THE EPIDEMIOLOGICAL SOCIETY; Mr. A. G. OSBORN; Dr. P. M. LATHAM; Dr. LIONEL DEALE; Mr. LOWNDES; Dr. T. H. BARKER; Dr. JAMES RUSSELL; Dr. F. PAGE; Dr. J. B. HARRISON; Dr. HYDE SALTER; Dr. GRALY HEWITT; Mr. T. SYMPSON; THE REGISTRAR OF THE MEDICAL SOCIETY OF LONDON; and Mr. P. HEWETT.

ON

## STRANGULATED FEMORAL HERNIA.

DELIVERED AT ST. GEORGE'S HOSPITAL.

BY

PRESCOTT G. HEWETT, Esq.,

SURGEON TO THE HOSPITAL.

MARY A. C., aged 51, was admitted into the Princess Ward on December 4th, 1862, with a tumour, of the size of a small orange, in the right groin. It was of a globular shape, with a well marked, narrow pedicle, and for the main part overlapped the right abdominal ring; it was quite hard, very painful, even when slightly handled, and there was great tenderness over the whole of the lower part of the belly, as high up as the umbilicus; there was constant sickness, but the bowels had acted three times during the day; the pulse was small, and the countenance sunken and anxious. The history of the case was a somewhat peculiar one. It appeared that the patient had had a tumour in the groin for seven years: this tumour had apparently been taken for a cyst, for it had been punctured several times, and clear fluid drawn off: no suspicion had been entertained as to its being a rupture, and she had consequently never worn a truss. She was much in the same state as usual, when the tumour suddenly became larger and very painful, and the other symptoms soon followed, and had existed about nine hours when I saw her, shortly after her admission into the hospital. I determined upon operating at once, and she was put under the influence of chloroform. The sac was a remarkably thick one; it contained a quantity of blood-tinged fluid, and a knuckle of small intestine which was of a very dark colour, and somewhat rough on its surface; the stricture was very tight, and the ring a very small one. A grain of opium was given shortly after the operation.

The operation was followed by deep-seated inflammation around and within the sac; but with this exception the case did remarkably well. The bowels were left alone until the ninth day after the operation, when, as there was some slight griping pain, an injection was given, and this was repeated on the following day, as there had been no action of the bowels; a slight motion followed, and the day afterwards the bowels were freely relieved after another injection. From this time, matters went on well; liberal diet was allowed in due course of time, and the patient was discharged, cured, on the 3rd of January, within a month after the operation.

In commenting upon this case, I would first call your attention to its peculiar history. There had been a tumour in the groin for a period of seven years; this tumour had apparently been taken for a cyst, and at different periods tapped, clear fluid being drawn off on each occasion; there had been no suspicion as to the tumour being a hernia, and consequently no truss had been worn. Suddenly one morning, this tumour increases in size; this is followed by repeated vomiting, and the belly becomes swollen and painful, but subsequently to all this the bowels act three times.

On the one hand, then, there was the history of the tappings, and the action of the bowels at three different times, since the setting in of the urgent symptoms; and, on the other hand, sudden increase

in the size of the tumour, soon followed by constant vomiting, and subsequently by pain and distention of the belly. By what was I led to operate in this case? By the increase in the tumour, followed by constant vomiting. Such symptoms pointed to an obstruction in the bowels, a knuckle of which had, I thought, slipped out of the belly. True, the bowels had acted three times since then; but this night, I told you, have come from the portion of bowel below the stricture. Sickness, alone, is then sufficient to warrant the surgeon in cutting down upon a tumour in the groin to ascertain its nature. And well was it that there was no dallying in this case, for the ring was a very small one, and the stricture remarkably tight. With such a state of things, a few hours more of strangulation would, in all probability, have led to irreparable mischief; and, as it was, the bowel was already of a very dark colour, and rough on its surface.

Thus much for the present case. And now let me say a few words on different points connected with strangulated femoral hernia in general.

First, as to the administration of chloroform in such cases. By many surgeons who have no hesitation in resorting to the use of chloroform in various operations, this anæsthetic is avoided in strangulated hernia, on account of the sickness and depression which occasionally follow its administration. Such symptoms after an operation for hernia would add greatly to the gravity of the case, and might, if severe and prolonged, lead to a fatal issue. Indeed, independent of operations for hernia, several cases are already known in which chloroform-sickness has gone on notwithstanding all remedies, and induced such a state of collapse that the patient has been in great jeopardy. And if this sickness should, perchance, occur after an operation for hernia, doubtless the danger of a fatal termination would be all the greater. It must be borne in mind, however, that chloroform-sickness of a severe character is, after all, of very rare occurrence; and, as far as my own experience extends, I cannot say that I have ever seen a case in which severe sickness has followed the administration of chloroform in an operation for hernia. Balancing, then, this evil of rare occurrence against the immense use of which chloroform has proved itself to be in the reduction of a strangulated hernia, I have no hesitation in resorting to its administration in such cases.

As to the taxis, that you know was not even attempted in the case which we have just been considering. And why not? The globular and pedunculated shape of the tumour made me think that this was one of the cases of strangulated femoral hernia in which the taxis would fail; and added to this there was the exquisite tenderness of the tumour, which showed that great harm might be done even by gentle pressure. In strangulated femoral hernia, the surgeon cannot be too careful in his attempts at reduction by the taxis; and, do what he will, the taxis will fail in by far the greater number of such cases—in three out of four, at the very least. Let it then be a rule with you in all cases of strangulated femoral hernia, and mind I am now speaking of femoral hernia only, to be very careful, very gentle whenever you may use the taxis. If you are to succeed, depend upon it you will do so by gentle pressure, which ought not, moreover, to be prolonged beyond a few minutes; if you fail, get the

patient under the influence of chloroform, and then try the taxis again, but on no account with any thing like force; and if you still fail under such circumstances, make up your mind to operate, and operate at once. The chances of success after an operation for strangulated femoral hernia may, literally, be calculated by the more or less time during which strangulation has been allowed to exist, and by the more or less force used in the taxis. And yet, what is the history of most of the cases of strangulated femoral hernia with which we have to deal in hospital practice? Rarely is it that the period of strangulation can be counted by hours: it is by days that it must be counted in by far the greater number of cases. Take, for instance, the twenty-two cases of strangulated femoral hernia in which I have had to operate in this hospital: in fourteen out of these twenty-two cases, the strangulation had gone on for two days and upwards, existing in seven out of these fourteen cases for three days; in two, for four days; and in one, for five days. In one single instance, it had existed for five, and in another for seven hours; and in the remaining six, the least period was twelve hours. And whilst thus strangulated, the bowel had, with very rare exceptions, been subjected to the taxis, repeated at various intervals, and applied with more or less force. Indeed, in several of the cases, the force had been so great that the skin covering the tumour was of a dark purple colour, the cellular tissue extensively infiltrated with blood, the sac itself filled with bloody serum, and the bowel discoloured from blood extravasated in its coats.

The damage done to the bowel during its period of strangulation varies very much according to the size of the ring, and the consequent amount of pressure. Thus, in cases of recent hernia, cases in which the bowel is strangulated when it first comes down, the ring is very small and the pressure very severe; in such cases, a very few hours will often lead to irreparable mischief, and hence the reason why operations are, as a rule, so much more fatal in recent than in old femoral herniæ. The amount of pressure upon the bowel caused by the stricture is, then, the great source of danger in all cases, but especially in recent cases, of strangulated femoral hernia; and hence the reason why I have so strongly urged you, if the taxis fail, to operate at once.

Opening, or not opening the sac, about which there has been so much discussion of late, is, I am firmly convinced, quite a matter of secondary importance, compared with the period of strangulation, and the more or less forcible taxis.

For my own part, I invariably open the sac in operating for femoral hernia. I have never seen any harm arise from opening the sac; and great harm may arise, in some cases, from not opening the sac. For instance, in cases, and they are not uncommon ones, where the sac contains both bowel and omentum, and in which the omentum is more or less adherent to the sac, how can the surgeon be sure that a bit of the bowel is not left in the sac? Again, in cases where the omentum forms a complete sac enveloping the bowel, the stricture may be in the neck of the omental sac. Thus it happened in a case operated upon by Mr. Cæsar Hawkins. The sac, which was very thin, was laid open, and in it was found a large mass of omentum somewhat altered in structure. The neck of the sac and Gim-

bern's ligament were divided, so that the finger could be easily introduced into the belly. The omentum was then carefully examined, and a knuckle of small intestine, of a very dark colour, was seen through its folds, which formed a complete sac; this omental sac was laid open; but, before the intestine could be returned, it was found necessary to divide the neck of this second sac, which formed a very tight stricture; the intestine was then easily reduced. And again, in recent hernia, where the thin, transparent sac has not as yet contracted adhesions with the neighbouring parts, and especially where it has become glued by recent adhesions to the bowel, the sac, if not opened, may be readily pushed up into the belly along with the bowel, and the strangulation thus continue. The possibility of such an occurrence was made manifest in one of my last operations, in which such a state of things existed; and had it so happened that I had not, in this case, opened the sac, it would have been pushed up into the belly when the bowel was reduced; and, as recent adhesions partially glued the bowel to the sac, and especially to its neck, the strangulation would have gone on.

I have said that I have never seen any harm arise from opening the sac in strangulated femoral hernia; but on the present occasion I shall, however, refer only to the cases which have fallen under my own care. Incidentally, I have already mentioned that I have at this hospital operated upon twenty-two cases of strangulated femoral hernia; and out of these twenty-two cases, four only terminated fatally. And now, in looking to the cause of death in these four cases, I find that in no single instance had the opening of the sac anything to do with the fatal issue. Indeed, as far as this part of the inquiry is concerned, one of these fatal cases might be set aside altogether; for death was, in this instance, mainly caused by internal hæmorrhage, of the existence of which there was nothing to cause suspicion. There was no bleeding at the time of the operation, and subsequently no oozing of blood through the wound. The bowel, which had been strangulated for four days, was very much congested, and the sac also contained a small piece of omentum. Previously to the operation, there was great tenderness over the belly; this tenderness went on increasing, and the patient sank in forty-eight hours. At the examination of the body, a quantity of blood was found in the cavity of the peritoneum; it coated the various viscera, but the largest quantity had trickled down into the pelvis. A careful dissection of the vessels around the ring was made, but no injury was traced in any one of them, save in a very small vessel given off from a branch of the epigastric artery, and from this the hæmorrhage appeared to have proceeded. As to the parts which had been strangulated, they were evidently recovering themselves.

But to return to the three remaining fatal cases; in every one of these cases death was evidently the result of the strangulation, and in no way of the sac having been opened.

In the first case, the hernia was an old one, and the period of strangulation three days. When admitted into the hospital, the patient, a man aged 63, was perfectly collapsed, and in such a state of debility that it was thought doubtful whether he could live through the operation. The sac was opened, and the bowel returned, as, although dark,

it did not appear to be gangrenous; but, a few hours after the operation, a copious discharge of thin faecal fluid escaped from the wound. The patient sank rapidly. At the after-death examination, the mucous membrane of the bowel was found completely ulcerated in a circle corresponding to the seat of stricture, and in two points the other coats had given way.

In the second case, the hernia was a recent one, and the period of strangulation two days; and in this case, too, two spots of ulceration perforating the bowel were found at the point which had been strangulated. The patient was a woman, aged 76.

In the third case, the hernia was also a recent one, and the period of strangulation four days. The patient, a young woman, was in a perfect state of collapse, with stercoraceous vomiting, and great tenderness over the belly, which was tympanitic. Forcible taxis and purgatives had been repeatedly tried before her admission into the hospital. The sac contained a quantity of bloody fluid, and the bowel was of a very dark colour, and mottled. The patient never rallied, and sank in twelve hours after the operation. Extensive peritonitis of a low form was found at the examination after death.

Excluding, then, the case in which death was evidently caused by internal hæmorrhage, I find that I have, in this hospital, operated upon twenty-one cases of strangulated femoral hernia, in all of which the sac was opened; and that out of these twenty-one cases, three have died—that is, at the rate of one case in seven.

Such results will more than bear comparison with the most favourable results published by the surgeons who so strongly advocate that the sac should not be opened in strangulated femoral hernia. True, the number of cases is small; and in a greater number of cases, I might perchance not be so fortunate as I have been; but that the sac should have been opened in these eighteen cases, and that they should all, notwithstanding this, have done well, proves, at any rate, that the real danger does not rest with this mode of operating.

In the after-treatment, shortly after the operation, I usually give some opium, the dose of which is regulated by the state of the patient; but, as a rule, I do not give more than one grain, and this is repeated, or not, according to circumstances. The bowels I make a point of not interfering with. You will have seen in the wards of this hospital many of the cases of hernia on which I have operated, in which there has been no action of the bowels for several days—a week I find to be a very common period among my cases, and yet the cases, as you know, have done well. This is a very different state of things from what it used to be some few years ago at this hospital, when a drachm of salts and some infusion of roses immediately after the operation, and every two hours, until the bowels had acted freely, was the rule.

But should any symptom attributable to the non-action of the bowels perchance arise after a few days, it is then advisable to give either an enema of warm water, or some castor oil, according to circumstances.

As to diet, that ought, as a rule, to be of a generous kind: fluid, until after the bowels have been freely open, and then a gradual return to the ordinary mode of living.

But I cannot conclude these few remarks, gentlemen, without once more impressing upon your minds the imperative necessity of operating without delay in strangulated femoral hernia, as often as you find that the taxis, fairly tried, has failed. Recollect that the great source of danger is in the strangulation, and that the less this is allowed to go on, the greater your chances of succeeding when obliged to operate. And this is a fact which you ought to be careful to stamp upon the memory of every person afflicted with femoral hernia.

## Clinical Lectures

DELIVERED AT

### CHARING CROSS HOSPITAL.

BY

HYDE SALTER, M.D., F.R.S.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS; LECTURER ON PHYSIOLOGY AND PATHOLOGY AT CHARING CROSS HOSPITAL MEDICAL SCHOOL; AND ASSISTANT-PHYSICIAN TO THE HOSPITAL.

#### LECTURE V.—ON THE STETHOSCOPE.

*Principal Uses of the Stethoscope.—Rules for its Construction: 1, as to Material; 2, Length, Thickness, etc.; 3, Shape, etc., of Extremities—Practical Hints for its Manipulation—Method of Applying—Choice of Whereabouts to apply—Determining Limits of Sound—Ausculting Females and Children.*

[Concluded from page 108.]

HAVING thus described to you what I consider the essentials of a good stethoscope, let me give you some practical hints for its manipulation.

1. *Method of applying and holding the instrument.* Choose your part—apex or base of heart, apex of lung, axilla, or what not—and if you are not particular to a quarter of an inch, select it with the view of avoiding inequalities, and securing the most complete and uninterrupted apposition. Then apply the stethoscope thus (fig. 5), holding it between your

Fig. 5.

first and middle finger of either hand, according to the ear you are going to listen with; then press it firmly, applying your pressure to the spreading part of the chest-end. In this way, all chance of obliquity and partial contact is avoided, and the direction of the parietes alone influences the direction of the instrument. Then, keeping the chest-end gently but firmly pressed against the chest, bring the ear carefully and exactly over the centre of the ear-piece; then, applying sufficient pressure to secure the firm contact of the pinna, so as to stop all

chinks and support the stethoscope, remove the fingers that hitherto had held it against the chest. That is the right way. What is the wrong? The right way is one; but, as in other things, the wrong ways are many. One wrong way is to hold the stethoscope near the ear-piece; another, to place it obliquely against the chest; another, to approach the stethoscope to the ear, when stooping to listen, as well as the ear to the stethoscope; another, to keep the fingers in contact with it after the ear is applied, and support unnecessary. If the stethoscope is held near the ear-piece, it is not at liberty to adjust its direction to the chest, its direction is regulated by the hand and not by the thoracic parietes; for in proportion to the distance from the chest-end that the stethoscope is held does its perfect adjustment to the chest's surface become difficult and a matter of chance. If it is held obliquely so that only one edge of the chest-end is in contact with the chest, and between the other and the skin there is a chink, the column of air in the stethoscope is not isolated, but is in communication with the external air, and that murmurous noise is generated, like that which one hears on applying the ear to a shell, and to which I have already referred. I have often seen this method of handling the instrument fatal to efficient auscultation, and have watched the auscultator listening with the greatest solemnity when he could not possibly have heard anything except the droning hum of an open stethoscope. Then again, when the auscultator is stooping to bring his ear to the stethoscope, he very often unconsciously brings the stethoscope to his ear, especially if he is holding it near the ear-piece, so that by the time the ear is adjusted the chest-end is tilting up on one edge, although it has just been applied quite flat. The only antidote to this is to press the stethoscope firmly against the chest, in the way I have mentioned, till the ear is fairly over the centre of the ear-piece, then press the ear firmly against it and keep the head fixed. Perhaps the commonest fault of all is holding the stethoscope in the hand while listening: this is perfectly unnecessary, for the pressure of the head against the instrument is quite sufficient to support it, and the continued application of the hand often produces disturbing adventitious friction-sounds.

2. In choosing the point at which you will listen, if the object of your search is such as to give you liberty of choice, choose those parts that are the least covered with muscle or fat. Sometimes half an inch will make all the difference. I have not unfrequently seen both medical practitioners and students listen on the thick edge of the *pectoralis* or *latissimus dorsi* when the movement of the stethoscope one inch or less would have thrown them into the axilla, with nothing but the thin digitations of the *serratus* between the stethoscope and the ribs. If, for example, you wish to ascertain the general character of the respiratory murmur, any part of the chest will, with certain qualifications, give you the information required; but no parts are so good as the axilla and the neighbourhood of the apices in front, because in none is the muscular and fatty integument thinner, and therefore in none is the sound clearer. This, however, involves a corollary; namely, that in estimating the standard of sound in different situations regard must be had to the amount of intervening fatty and muscular tissue in those particular situa-

tions. For an amount of indistinctness and obscurity of breath-sounds that would be abnormal if heard in the axilla, would be quite natural if heard through the female breast.

3. In endeavouring to ascertain the limits of a sound, work gradually towards it and then gradually from it; the former will give you the limits of its first appearance, the latter the point of its first diminution. But in estimating the extent of the seat of a sound by the limits of its audibility, the character of the sound must be regarded as well as its distribution; for a loud sound transgresses the limits of its generation more than a feeble one, a dry sound is heard further than a moist one, and a deep sound than one of high and slender pitch.

4. In auscultating a female's chest, if you should wish to apply your bare ear to the bare skin, (and I do not hesitate to say, that for getting the most perfect information it is sometimes extremely desirable that you should,) or if you want with your bare hand to examine a friction or souffle fremitus, always pave the way by first applying the stethoscope. A physician in search of a diagnosis is a being of no sex, he is a mere machine; a woman's bare breast is to him only so much integument intervening between him and the object of his interest; he sees twenty in a day, perhaps, and thinks no more of seeing a female chest than he does a female tongue. But it is not so with our patients; and a woman in undergoing a thorough and free auscultation does so at the sacrifice of a certain amount of instinctive sensitiveness and modesty. No doubt, no sensible or reasonable woman would for a moment hesitate, or balance feeling against thorough results; but still there is the feeling and it has to be overcome, and we cannot be too careful not to do violence to it. It may seem a mere trifle, a mere sentiment; but it is not, it is a most important element in our constitution, and plays a most important part in the social and moral system of our race. There is a very good French proverb to the effect that "Modesty is the rampart that nature has raised around virtue"; and a Latin one more generally and less happily expressed—"Pudore amisso omnis virtus ruit." And he would be a bad philosopher who would regard as a trifle a feeling normally universal, and in its nature respectable and beneficent.

5. There is nothing more difficult than using the stethoscope with children, (very young children I mean,) and successful auscultation with them often requires a good deal of strategy and *finesse*. Once set a child crying, and it is all over; you get nothing but the held breath and the roar. The difficulty is enhanced from the fact that different ages and different children require different management. Some children are afraid, and roar as soon as you produce a stethoscope, although they do not mind your applying your bare ear to their chests. Others enjoy it as a sort of game, and are immediately quiet and good when you apply the "trumpet" to them. Sometimes, therefore, it is better to use the stethoscope, and sometimes the bare ear; sometimes to shew the instrument, and sometimes to hide it. As a rule, older children are quieted and interested by the mystery of the stethoscope; the younger ones are afraid of it and resent it. My practice with infants is this: never commence by auscultating them; always occupy them while doing it; always listen to the back first; always listen with the bare ear before

applying the stethoscope; always warm the stethoscope before using it. I have known it of inestimable value as a toy, occupying the little patient in front, while I have been stealing a march on him in the rear and employing immediate auscultation without his knowledge.

## Remarks

ON

## THE MOLECULAR THEORY OF ORGANISATION:

IN REPLY TO DR. BEALE.

BY

JOHN HUGHES BENNETT, M.D.

PROFESSOR OF THE INSTITUTES OF MEDICINE, AND SENIOR PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF EDINBURGH.

I AGREE with Professor Beale that there are few questions of greater interest to those who are investigating the principles upon which medicine is based, than a consideration of the laws governing the ultimate molecules of which every living organism is composed. I have great pleasure, therefore, in replying to his remarks; because, probably from want of clearness on my part, he has misapprehended the nature of the theory which, after long and mature consideration, I have ventured to place before the profession in the pages of the *Lancet*.

Dr. Beale thinks that, because I have described histolytic molecules as being *often* larger in size than histogenetic molecules, and as being *sometimes* associated with the *débris* of broken down textures, there is a discrepancy in my figuring the latter in disintegrated tubercle unconnected with such *débris*. But I have never stated that the one class of molecules may not exactly resemble the other; and a glance at the figures representing the development of *ascaris mystax* must prove the contrary. Moreover, as it is an essential part of my theory that the histolytic molecules of one period may become the histogenetic molecules of another, there is nothing contradictory in making one figure represent both. Dr. Beale says that I "surely will not maintain that lifeless particles become aggregated together and form a living mass." But tubercle is not lifeless, and is subject to the general law of organisation. As to when, how, and where life is communicated to matter, these are questions I need not now discuss.

Dr. Beale says I ignore the use of high powers and reproduce figures ten years old, drawn under a magnifying powers of 250 diameters linear, an enlargement far less than he and others employ in the present day. I have frequently used powers varying from 700 to 1200 diameters linear; but in rare cases have gained any advantage thereby. If a thing can be seen distinctly under a low power, we seldom see anything new by making it four times as big. Inexperienced persons, also, by the use of such high powers, are peculiarly liable to be led into error. For the purposes of illustration, therefore, I consider that in most cases (not all), a power of 250 times

linear is amply sufficient, and it has the great merit of saving space and expense in wood cutting.

Dr. Beale says that the term molecule can scarcely be properly applied to a body nearly as large as a blood-corpuscle. But I can see, say in milk, no difference in structure between the larger and smaller molecules. I have always maintained that, whatever powers are employed, you cannot reach the ultimate molecule; I am far, therefore, from disputing that many of them may be less than the twenty-thousandth of an inch, and still possess all their vital and physical properties.

In the formation of vibriones, I have certainly never seen two particles in the very act of uniting, any more than I presume Dr. Beale has seen them divide under his eye. Either view is a matter of inference. But if Dr. Beale has been fortunate enough to see them actually divide, this is no objection to my theory, as there is no reason why they may not form in one way and multiply in another. In the same way, having been produced by precipitation, they may increase by absorption or imbibition of nutritive fluids.

Dr. Beale thinks it an objection to my statement, that the formation of bone is connected with the molecular law of aggregation, because "the laminae of the Haversian system are formed layer *within* layer, while the layers of calculous matter are deposited layer *upon* or *outside* layer". But molecular aggregation may take place equally from within or from without; and, as in bone the nourishing fluid is derived from vessels lining the Haversian canals, it is only from within that one could expect such aggregation to be produced.

Dr. Beale thinks there is some confusion in the definition of molecules, because they may be living and dead, simple and compound; may originate from others, and be precipitated from fluids; may be so large as the 1-4000th of an inch, and so small as not to have been reached by the highest magnifying power; and because they have different properties. I can see no inconsistency in all this. Other elementary parts—for example, fibres—possess equal differences. Cells also vary in size, origin, chemical composition, complexity, and properties; yet they are still cells. As to whether molecules of the same kind or molecules of different kinds become aggregated together, there can be no question that coalescence may occur in compound organisms, both between the same and between different molecules, although the former is the most common. When a minute particle of oil is precipitated in an albuminous fluid, there is aggregated round the former a layer of albumen; and so a simple is at once converted into a compound molecule.

I have thus endeavoured to answer all the topics contained in Professor Beale's communication, in which I have been unable to see either facts or arguments in any way opposed to the molecular theory of organisation. On the other hand, were it necessary, I could easily prove from the valuable facts Dr. Beale has placed on record, and from the laborious investigations which he has made into the structure and growth of the tissues, that he has himself furnished most powerful arguments in its support.

I would deprecate further discussion on this matter until the whole of my lectures are published, when I shall be most happy to argue the subject, in all courtesy, with any opponents who, like Dr. Beale, possess an earnest desire to elucidate the truth.

## HOSPITAL PRACTICE:

METROPOLITAN AND PROVINCIAL.

### BIRMINGHAM GENERAL HOSPITAL.

CASES OF RHEUMATIC PERICARDITIS.

Under the care of JAMES RUSSELL, M.D.

PERICARDITIS of the rheumatic variety presents, in its tendency to recovery, a striking contrast with the non-rheumatic form of the malady; the tendency of the latter being, too generally, to death. Ormerod, as quoted by Dr. Markham (*Diseases of the Heart*, p. 16), states "that 91 per cent. of his non-rheumatic cases were fatal, whilst of the rheumatic sort 18 per cent. only were fatal." Dr. Gairdner (*On Pericarditis*, p. 29) gives a still more favourable aspect to the disease, by asserting: "Of rheumatic pericarditis and of pericarditis without previous disease, acute or chronic, I have not had under my own personal care a single fatal case." Elsewhere, however, he rather modifies his assertion (p. 32): "As physician to the Royal Infirmary, I have not had under my care a case of rheumatic pericarditis fatal during the acute period of the attack." There can, I think, be little doubt that the more favourable result of cases of this disease in the present day mainly results from the single circumstance of our recognising in the disease a tendency to health rather than to death, and thus freeing our minds from much of the over-anxiety which led to mischievous interference, and leaving ourselves free to obey the indications afforded by each particular case. The same remark is applicable to pneumonia with, probably, still greater force.

Nevertheless, among various cases of rheumatic pericarditis, we witness the widest diversity as regards the intensity of the symptoms, from complete latency to extreme distress in the patient, exciting most serious alarm for the issue of the case—alarm sometimes justified even by death. The following cases illustrate such diversity. In the severe forms of the malady, our main, if not our entire, interest is concentrated upon the condition of the heart's fibre; it may be truly said that almost, if not quite, all the general symptoms, and some of the most important physical signs also, relate to the manner in which the heart is exerting its contractile power; the chief sufferings of the patient result from failure in the heart's power. Thence also arises the danger of the case; and by the same element, more than by any other, we ought to be guided in our choice of measures.

The contractile power of the heart is liable to be lowered in pericarditis by more than one cause. There is fluid effused and compressing the feeble auricles; there is also the immediate neighbourhood of acute inflammation, with its paralyzing influence upon muscular fibre. We see each of these influences in powerful operation in the second case below, doubtless intensified by the severe treatment to which the patient was subjected. There is, however, another peril to which the muscular fibres are exposed in this disease, which does not exhaust itself in immediate effects. The inflammation may extend from the pericardium to the tissue of the heart itself, and may permanently cripple the muscular fibre. The first of the following cases affords an interesting illustration. Throughout the case, evidence of depressed cardiac power was manifest. Before the pericardial signs had well developed themselves, the duski-ness of face, the tendency to delirium, the high rate of the pulse and respiration, and the feebleness of the first sound

of the heart, suggested that the muscular tissue of the heart was already suffering; most serious evidence of great congestion of the heart's cavities afterwards appeared; and after the acute symptoms had passed away, even though recovery seemed progressing, the same indications prevented our feeling at ease respecting the chance of perfecting the cure. The history of the case, except in its longer continuance, almost resembles one of pyæmic pericarditis, of which an interesting example will follow; a form of the malady in which Dr. Kirkes has shown that the muscular fibre of the heart is primarily affected by the formation of so-called secondary, or more properly tertiary abscesses, in its substance. The morbid changes exhibited the disorganising result of inflammation in the deposit of fat and of fresh fibrous tissue amongst the muscular fascicles, crippling the latter, and causing them to atrophy; whilst the unfavourable condition of the entire organ, as regards nutrition and function, was further evidenced by the interstitial fatty change—a true fatty degeneration—which was commencing in the fascicles of the more healthy part, just as occurs in cases of ordinary valvular disease, when at last the heart fails in the struggle.

The immediate cause of death was of the nature of an accident, but one to which the patient's condition directly led—formation of a fibrinous mass in the right cavities of the heart. With a right ventricle firmly attached to the bony walls of the chest, its thin walls more than half converted into fat, and the patient's blood loaded with fibrine, as is the case in acute rheumatism, every circumstance combined to favour this fatal occurrence.

It is worthy of note how quickly and completely the pericardial adhesion had consolidated itself. Ten days before August 31st (when she was first seen) is the earliest period at which the inflammation could possibly have commenced; friction-sound ceased to be heard on September 30; the patient died on November 9th, with very close adhesions, almost identifying the pericardium with the heart, and both with the osseous wall of the chest.

CASE I. Caroline Taylor, aged 13, servant, was admitted August 30th. She had had a hard place, and had been much exposed to wet and cold in an open shop. She had been ill with acute rheumatism for ten days; and three or four years ago, was confined for a few days with the same complaint. Her father died of rheumatism and diseased heart.

On August 31st, her chief symptoms are reported as follows. There was considerable effusion in the joints of the upper and lower extremity. She perspired freely. Pulse 122, respiration 44. The first sound of her heart was decidedly rough; the roughness being most pronounced under the sternum, on a level with the second intercostal space; in quality, the abnormal sound had more of a blowing than of a rubbing character.

Notwithstanding the unfavourable prognostics attending the opening of the case, it was three days longer before the pericardial inflammation developed decided physical signs, though during that interval the patient's condition boded evil. The pulse and respiration remained at 132 and 34. There was so much general distress added to the severe rheumatic affection of the joints, that for one day opium was prescribed at the rate of half a grain every two hours. Moreover, a very decided tendency to delirious wandering manifested itself from the first; and although there was no physical sign indicative of an increase in the cardiac affection, yet the impulse and the first sound of the heart were very feeble, and a marked leaden hue of the features forced itself early upon our attention. Her urine, I should observe, was speedily rendered alkaline by potash.

On the fourth day (September 3rd), no further doubt as to increase in the inflammatory affection of the peri-

cardium remained; the cardiac dulness was extended; and, by the evening of September 4th, rose to the first intercostal space. A remarkably dry-to-and-fro friction-sound was distinct over the upper left chest, most intensely beneath the upper part of the sternum. The pulmonary portion of the chest, however, remained in a satisfactory condition. The pulse and respiration mounted to 152 and 68. Inspiration was peculiarly sighing and hard to draw.

The general symptoms of the disease became rapidly more urgent, and evidence of depressed cardiac power, and of consequently loaded cavities, more unmistakable. The lips were first livid, and then almost black; the face pallid and leaden; its expression anxious, and indicative of great distress. The delirium was constant; she was incessantly springing up in bed; and frequently divested herself entirely of her clothes; or she lay uttering a continuous melancholy moan. Her bowels were purged, and she passed her stools under her; her urine was abundant. It is to be observed that notwithstanding the effusion of fluid which had taken place in the pericardium, the friction-sound was maintained, though with lessened power. She was ordered tincturæ opii *mxv*; potassæ bicarbonatis, *ʒi*, every three hours; and to have a blister applied over the heart. Ten ounces of wine were ordered.

Such was the state of things, with some variations, through September 3rd and 4th. On the following morning, a tendency to improvement was manifested. The pulse and respiration were 128 and 47; the lips had lost their lividity, though the face was still leaden; the delirium was less persistent, and the patient was easily roused. Once only a catheter was required, and one stool was passed involuntarily.

A considerable tendency to quiet sleep accredited the evidence of amendment which was now established.

It was not, however, until September 30th that the physical signs indicated entire removal of the fluid. Previously to that date, indeed, the effusion had again increased. On the 30th, the rubbing sound had perfectly ceased; but its disappearance disclosed a loud mitral blowing sound, which for eighteen days previously had been rising into notice, distinct in quality from the rubbing sound. During the interval, the patient's health had much improved; her appetite for meat had returned; and she had lost much of the discomfort which yet remained. But it was remarked, as being inconsistent with this general improvement, that the region of the heart was liable to be the seat of uneasiness; and what was more important, that the pulse and respiration continued persistently high: on the thirty-second day from her admission, they were 128 and 40 to 46; and no explanation of this abnormality was offered by the condition of the lungs. Moreover, her face was easily rendered livid.

Three weeks more (October 19th) saw the patient sitting up for a short time, with good appetite, improved nutrition, tranquil countenance, and increased force in the heart's impulse. The mitral bellows-sound had attained a musical pitch. Still, notwithstanding the favourable aspect of the case, the pulse and respiration were never below 124 and 28 or 30; the respirations sometimes rising to 36, and on November 6th to 42; and, in consequence, I never felt at ease respecting my patient's progress.

The date just mentioned was the seventy-ninth day of the case. She was on that day pale and feeble, and complained of rheumatic pain. On the next day (the 7th), the pulse and respiration were 144 and 76; her breathing was panting; she had very severe paroxysmal pain in the left side, below the mamma and across the front of the chest; skin cool; face pallid, but remarkably free from any expression of distress.

She died three days afterwards. The pulse and respiration rose to 140 and 96; incessant vomiting came

on; she could only speak a few words consecutively. Her pupils were natural; her face pallid; the jugular veins not distended. The pain was at times intense. She did not cry out, but lay on her left side moaning, and in such distress that, almost against my judgment, I again resorted to the opium, ordering one-third of a grain of morphine every third hour, with some benefit. The evening before death, the pupils were greatly contracted, and the morphine was omitted.

**SECTIO CADAVERIS**, thirty hours after death. Close and firm adhesions united the pericardium intimately to the sternum, and to each lung. All the large veins were remarkably full of loosely coagulated dark blood. The pericardium was almost identified with every part of the heart's surface with which it could be brought into contact. The left ventricle was somewhat dilated, and its walls were thicker than normal. A mass of pure yellow firm fibrine occupied a large part of the right auricle. Passing into the ventricle, a continuation of the same mass lay upon the septum, to which it was loosely adherent; and from this portion a cylindrical process, of the thickness of the largest lead-pencil, passed up the pulmonary artery, to which, however, it was hardly attached; it followed the bifurcation of that vessel, terminating at the root of the lungs. Some loosely coagulated blood lay in the auricle upon the fibrine. The aorta was much contracted. All the valves of the heart were healthy, excepting the mitral, each curtain of which, but chiefly the parietal, was contracted and corrugated, without being thickened by adventitious deposit. The endocardium was healthy. The muscular tissue of almost the entire surface of the heart beneath the adherent pericardium presented a very marked yellow colour for the depth of about one-eighth of an inch; the altered colour blending gradually into that of the normal tissue, precisely as occurs when a superficial deposit of fat upon the heart has encroached upon its muscular fascicles. In one part of the right ventricle, the change in question involved nearly the entire wall. In the remainder of the walls, the tissue presented a perfectly normal aspect.

The changed portion in some parts offered considerable resistance to tearing by needles. Large oil-globules, sometimes in extensive groups, sometimes more loosely scattered, were interposed among the fascicles of the diseased portion of the walls, and appeared to have occupied the place of many. In addition to the oil, a fine fibrous tissue could be seen crossing the fascicles, in some portions constituting the entire substance, intermixed with oil; large strands of beautifully waving fibrous tissue fringing the margin. A large number of the remaining fascicles were perfectly opaque, from a dense collection of minute oil-globules; yet there were others, side by side with those most diseased, which exhibited the normal structure with beautiful distinctness. Free oil-globules of minute size floated around the specimens in such abundance as to impart to the water the aspect of an emulsion.

The remainder of the heart's tissue exhibited a condition of fatty degeneration to a very moderate extent. Certain fascicles were opaque; but the majority retained their transverse striae, and merely presented small groups of bright globules. The septum had advanced far more in this alteration than the walls. There were no free oil-globules. The lungs were very oedematous, but far from being anæmic, though equally far from being loaded with blood. Nearly the whole liver showed itself below the ribs—no doubt from protracted depression of the diaphragm during the final dyspnoea; it weighed three pounds. Its tissue was anæmic. The kidneys were healthy, but very anæmic.

[To be continued.]

## Original Communications.

### ANEURISM OF THE ARCH OF THE AORTA : PRESSURE ON THE SUPERIOR VENA CAVA.

By ASHBY G. OSBORN, ESQ., Northampton.

**SUMMARY.** *Aneurism of the Arch of the Aorta, below the Origin of the Arteria Innominata : Characteristic Obstruction to Return of the Venous Blood from the Neck and Face: No Abnormal Valvular Sound: Bronchitis: Death.*

A WELL proportioned English yeoman, aged 40, whose brandy and water cost about £10 *per annum*; drove a very hard-mouthed horse a distance of eighteen miles at the beginning of November 1852. Within a fortnight he perceived peculiar fullness of the face and neck—a bloated sensation; and it was remarked by his friends how unusually fat his face seemed. In company he would sometimes hang down his head, to show how much this alteration in position increased the turgescence and lividity of his countenance. The surgeon to whom he applied for advice examined his heart, but neither he nor I could find anything abnormal in its rhythm or sounds. There was slight cough; but the face and neck were the only parts congested.

Purging with jalap and elaterium, and cupping, gave temporary relief; but we both thought unfavourably of the case. The local affection remained unimproved, but he continued his customary active life for two months longer, *i.e.*, till January 1st, 1853, when he again drove over the same ground, *viz.*, from London to Brentwood, and felt the cold severely.

The following day (Sunday) he was worse; the turgescence of the face had by the evening become extreme; he felt pain and uneasiness at his chest, and great pain in the region of the kidneys; there was slight cough without expectoration; almost stertorous breathing; and the small quantity of urine passed contained much blood. I do not find in my notes that he was unconscious.

The case being regarded as one of local dropsy from some disease of the kidneys aggravated by cold, the *indication* seemed to be to relieve the local renal congestion which was looked upon as the origin of all the mischief. He was bled to twenty ounces; and a dose of calomel and jalap was given immediately, and an ether mixture every three hours.

The prognosis was very unfavourable.

Dr. Grouse of Brentwood saw him for the first time on January 3rd, and thought there was unusual *resonance* of voice just at the centre of the upper third of the sternum. From the history, and this auscultatory sign, he suspected there was a tumour of some kind originating in the over-straining, and pressing upon the superior vena cava.

For nearly a fortnight, our patient continued to improve under the treatment adopted; the countenance shrunk, and with quiet and small doses of mercury became much more natural. The urine gradually returned to its normal condition. He relapsed, however, when moved from his own to another room, that he might sit up by a fire in his bedroom; bronchitis supervened; and he died on January 12th, 1853, nearly ten weeks after the commencement of the symptoms.

**AUTOPSY.** There was a cicatrised appearance of the coats of the ascending portion of the arch of the aorta, just before the commencement of the arteria innominata, and in the immediate neighbourhood, considerable aneurismal dilatations sufficient to enclose a large orange, pressing, of course, on the superior vena cava. There was a large quantity of clotted blood in the aneurismal sac.

The valves were quite healthy, and none of the large vessels were involved. The lungs were œdematous.

**REMARKS.** Perhaps the first thing worth noticing in this case is, that a large aneurism, probably of sudden origin, should exist so near the aortic valves without effecting any difference in their sounds, or producing that peculiar vibration which we call the aneurismal "whir."

The habit of constantly stimulating the system which this man had pursued for some years, probably softened the coats of the arteries, and thus rendered them less able to bear tension without yielding.

The termination of the case shows the value of Hilton's remark that there is never local congestion, especially of a venous character, which may not be explained by the existence of some obstruction to the withdrawal of blood from the part; here the venous congestion of the countenance was mistaken for the flushed face of renal disease (the apoplectic seizure of albuminuria).

The pathology seems to be this: by great muscular exertion the circulation of blood through the system is accelerated, but when the muscles are kept in a contracted state for some time, the entrance of blood into their texture is impeded, and thus the backing up of the stream takes place between the propelling power—the heart, and the obstruction—the contracted muscles.

In this instance the heart was acting with unusual force, whilst the muscles of the arms and chest were firmly contracted in controlling a hard-mouthed horse.

Had the arterial canal, particularly its middle coat, been in a healthy state, it might have yielded temporarily, and, perhaps, afterwards regained its calibre without any portion having given way, but this not being the case its middle coat ruptured, and thus an incurable disease was set up.

The temporary relief experienced from the treatment and rest recommended, can be accounted for by the bleeding and drastic purgatives diminishing the quantity of the circulating fluid, and calming the action of the arterial system.

The *practical observations* to be derived from this case are:—

Never rest satisfied till the cause of partial congestion is clearly ascertained.

Distinguish carefully the venous congestion from general fullness of the vessels, as in a flushed face.

Wherever there is reason to fear that the return of venous blood to the heart is impeded by some cause situate within the thorax, too much care to avoid cold cannot be taken, for in this case, though the aortic aneurism would have gone on to a fatal termination, yet the patient's death was occasioned, and no doubt much hastened, by bronchitis of organs already gorged with blood, and not directly from the pressure of the aneurism on the superior vena cava; and the bronchitis was caught in merely moving from one bedroom to another.

### CANCER OF THE BLADDER.

By F. PAGE, M.D., Southsea.

IDIOPATHIC cancer of the bladder is considered by most authors as a very rare disease. Some of high standing, as Sömmerring, deny wholly the existence of primary cancer of this viscus; Lallemand affirms that it is extremely rare; Civiale gives authority to the prevailing notion of the rarity of the disease; Sir B. Brodie also says he never met with a tumour wholly resembling scirrhus.

A case of this kind having lately come under my care, I think it is not altogether void of interest, and may be of use in forming a correct diagnosis in similar cases.

A. B., a man aged 64, applied to me on December 3rd. He was much emaciated, and appeared sinking from or-

ganic disease. He had been ill twelve months, gradually getting worse.

The symptoms were constant pain in the bladder; frequent desire to pass urine; increased and unbearable pain after each effort; striking lancinating pain through the perineum, anus, and the end of the penis. The urine was constantly bloody. The bladder was never distended. I sounded him, but found no stone.

On examination by the rectum, the prostate was found not enlarged, but I felt a hard circumscribed tumour in the posterior parietes of the bladder. The diagnosis which I formed was that of cancer in the bladder. Under the use of suppositories, anodynes, etc., the symptoms somewhat mitigated; but debility increased, and he died on January 10th.

On *post mortem* examination, there was found a circumscribed tumour of the size of half an orange, situated behind the prostate in the floor of the bladder. Its surface was softened down and ulcerated; it was covered with irregular fungoid granulations, with deep interstices, filled with soft pulpy matter. The base of the tumour was three-fourths of an inch thick. The tumour was of stony hardness when cut through, of a white glistening colour, and presenting very clearly cancerous stroma. The peritoneal covering was normal.

It appears that the deposit had its origin in the submucous tissue, involving the mucous membrane, and eventually ulcerating internally. Cancer-cells, with nuclei, were visible under the microscope.

### MIDLAND BRANCH.

CASE IN WHICH BILIARY CALCULI ESCAPED THROUGH A SINUS IN THE ABDOMINAL WALL.

By THOMAS SYMPSON, Esq., Lincoln.

[Read December 12th, 1862.]

C. F., aged 25, unmarried, a pallid, sallow complexioned countrywoman, having light hair and eyes, was admitted, under the care of Mr. Sympson, into the Lincoln County Hospital, on December 21st, 1857.

The opening of a sinus was seen on a level with and about three inches to the right of the umbilicus, through which a probe passed deeply upwards and outwards towards the right hypochondrium. The sinus yielded a free discharge of thin pus; and the adjacent soft parts were greatly thickened and indurated.

On the 22nd, a more particular examination was made, when the skin was found to be clammy, and the extremities disposed to be cold. The tongue was clean and flabby; the pulse 96, small and soft; the urine copious and pale; the bowels were said to act regularly; the catamenia had been absent since the commencement of her illness.

She stated that up to six months ago she had always enjoyed good health; but that she was then seized with a severe pain in the hepatic region, accompanied with jaundice, and followed by a swelling, which slowly descended towards the umbilicus, and, six weeks afterwards, was opened by a surgeon, when a teacupful of pus was evacuated. Since then, the jaundice had recurred several times, and the matter escaping from the sinus had occasionally assumed a bright green tint. The presence of a solid substance at a considerable depth from the surface was detected by a probe; but an attempt to reach and remove it by means of forceps proved unsuccessful.

She was placed on a liberal diet and tonics, and a linseed-meal poultice was directed to be applied over the fistula.

By January 10th, 1858, several biliary calculi had

passed through the fistula. By February 24th, she had got rid of more gall-stones, the discharge was diminishing in quantity, and she had much improved in health. The calculi varied in size from that of a millet-seed to that of half a horse-bean, and in tint from almost white to a deep brown; they were distinctly faceted. On every occasion of their passing, she had great pain in the right hypochondrium for a few hours prior to their appearance; the discharge from the sinus then became of a green colour, and then one or more of them escaped, with instant relief to all the symptoms.

On April 26th, when she was discharged from the hospital, several more gall-stones had passed; there was scarcely any discharge from the sinus; the surrounding thickening and induration had almost entirely disappeared; and her general health was completely re-established.

Roughly analysed, the calculi appeared to be composed of cholesterine, biliary colouring matter, and phosphate and carbonate of lime. One of them was made up of almost pure cholesterine.

### LANCASHIRE AND CHESHIRE BRANCH.

ON THE TREATMENT OF ASCITES AND ANASARCA.

By J. BIRKBECK NEVINS, M.D.(Lond.), Liverpool.

[Read December 18th, 1862.]

THE principle of treatment in these diseases which I wish to lay before you is, the importance of *operating early for the removal of the fluid by means of tapping or by acupuncture, instead of looking upon this method of treatment as the last plan we should resort to*. I believe that, when the mechanical removal of the fluid is effected at an early period, the chances of the patient are much improved; and that, instead of regarding tapping merely as a palliative to relieve the last urgent sufferings of the sick person, we ought to look upon it as an important curative agent. As I am not aware that this course has been prominently laid before the profession, I am desirous of stating the grounds upon which I recommend it, though it is very possible that the same reasons and the same treatment may have been suggested by other members of the profession, and have escaped my notice.

I have frequently observed the difficulty experienced in obtaining the free action of diuretics in cases of anasarca, until the fluid has been removed by some other means, after which the diuretics have produced the desired increase of urinary secretion; and, as a consequence of this, the further accumulation of fluid in the cellular tissue has been prevented. The means by which the fluid has been removed in the first instance have sometimes been copious sweating in a steam-bath, sometimes free purging by hydragogues, and at other times acupuncture of the legs and feet; but, in whatever way the object has been accomplished, the effect has been the same—viz., the natural action of diuretics, which had previously failed to operate.

In looking for an explanation of this phenomenon, I have come to the conclusion that the secreting portions of the kidneys are so enfeebled in their action by the pressure of the accumulated fluid present throughout the cellular tissue of the body, that they are unable to perform their duties aright, until the pressure is removed by some of the various methods just mentioned. The steam-bath or hydragogues would naturally be tried in the first instance; but, if they do not *speedily produce the desired effect*, I urge the early employment of *acupuncture*, and think the results of my experience are now sufficiently extensive, to warrant my bringing the subject thus prominently before my medical brethren. I have for some years laid this principle before my class

in lecturing on diuretics at the Medical School; but I have waited for accumulated experience before making more public mention of it.

In addition to its effect in promoting the action of diuretics, I consider the early employment of acupuncture important with reference to the condition of the patient's skin. When it is employed early, and before the skin has become enfeebled by the great and long continued distension, I have never seen any bad consequences follow the operation; but when it has been delayed to the last moment, and the legs have long been swollen to a painful extent, I have seen inflammation follow the operation, which has been troublesome in more than one instance.

In performing the operation, I advise that a few punctures only should be made—say half a dozen in the first instance—in one leg and foot; and that the patient should afterwards sit up as much as he conveniently can. The limb should be folded in flannels, which should be frequently changed as they become wet; and it is frequently necessary to apply warmth to the foot in bed. I recommend the employment of a common stout round sewing needle, in preference to a cutting edged needle, which I have for some time ceased to employ, as I have seen the wounds made by a three-cornered needle followed by inflammation more frequently than those made by a round one. The round punctures do not allow the escape of the fluid quite so freely as the others; but the comparative freedom from subsequent inflammation is important; and the operation with a common needle supplied by the patient himself, appears much less formidable to him than when the instrument is taken from the surgeon's instrument-case. As soon as the oozing of fluid ceases, the operation should be repeated if the swelling still continue.

With reference to the treatment of *ascites by early tapping* I have less extensive experience; but the following cases appear to me to hold out sufficient encouragement to warrant the fair trial of any plan which gives us reasonably increased hopes of cure in so generally hopeless a disease as dropsy of the abdomen. When the ascites is apparently dependent upon simple disease of the serous membrane (as, for example, in hydrocele), I think we have considerable encouragement in hoping for recovery; and even if it is due to cardiac obstruction, or to disease of the liver, I should still adopt the same mode of treatment, because it offers tangible advantages to the patient, with no corresponding disadvantage, so far as my experience extends.

It is familiar to us all how difficult it is to obtain the good effects of elaterium, in consequence of the vomiting which it excites; and, owing to this circumstance, we are frequently obliged to resort to tapping merely as a palliative, to relieve the urgent sufferings of the patient. Now, if the delay of the operation enabled us to make one tapping suffice for cure, we should be warranted in urging our patient to bear his sufferings, in the expectation of radical relief; and he would be repaid for his patience. But, since we find that repeated tapplings are the rule, and not the exception, it appeared to me very doubtful whether, after all, the benefits from delay did repay the prolonged distress from waiting; and I, therefore, repeated the tapping as soon as the patient became uneasy, without waiting for positive suffering.

I have further observed that, in some cases, hydrogogues acted upon the bowels after the patient had been tapped, although they had produced vomiting, or failed to purge before the operation; and I venture to suggest, therefore, that in this case also, the removal of pressure enables the organs to perform their functions, which they were previously unable to do.

I have now adopted this plan of treatment in three cases of ascites, which have resulted in perfect cures. The first case was that of a woman in whom the early tapplings were delayed in accordance with our usual

practice, and she was tapped many times before the fluid ceased to accumulate; but at length she was discharged cured, and died eighteen months afterwards of some other disease. The second patient was a man, who recovered after three tapplings; and the third was a woman, who also recovered after three tapplings.

I regard *constant mechanical support of the abdominal walls as a very important part of the subsequent treatment*, by enabling the tissues to regain their natural tone and vigour, after the extreme and enfeebling distension to which they have been so long subjected; and I, therefore, strictly enjoin the constant use of a flannel abdominal bandage, which I do not allow to be given up until the fluid has ceased to reappear.

In the course of *one or two days after the operation, I always resume the use of elaterium or jalap* in such doses as the stomach will bear without sickness, which ought always to be carefully avoided; and I have frequently found that a single pill daily, containing one-sixteenth of a grain of elaterium, produces copious watery purging without sickness after the operation, though the patient derived no benefit from it before the tapping.

The health should be sustained by a liberal diet, of which malt liquor or spirits may form a part or not, according to the circumstances of the case. Iron tonics have also appeared to be useful.

I feel that some apology is necessary for laying so much stress upon the results of so small a number of cases as the three which I have brought before you; but the principles upon which the treatment is based appear to me to be rational; and, if we can throw even but a little hope into the treatment of a disease which is generally so intractable as ascites, our patients cannot be great losers, and may possibly be great gainers. I trust that the kindness of my medical brethren will induce them to communicate to the profession whether their experience in future bears out or contradicts the principles now laid down; viz., that, in the treatment of ascites and anasarca, we ought to *resort early to the mechanical removal of the fluid*, instead of considering tapping as a last resource; to *employ long continued mechanical support afterwards*; and to *administer such doses of appropriate medicines* as the patient's stomach will bear, *early after the performance of the operation*.

*Discussion.* In the discussion which ensued, several members confirmed the observation about the increased action of remedies after the operation of acupuncture; and it appeared to be thought that the plan of treatment recommended in the paper offered a reasonable ground of hope, which rendered it deserving of trial.

**SCIENCE IN TURKEY.** The lectures on chemistry in course of bi-weekly delivery at the Dar-il-Fanoum, Constantinople, by Dervish Pasha, have attracted large and enthusiastic audiences. The lecture-theatre is very comfortably fitted up *à la Européenne*, and the lecturer is amply provided with excellent instruments, diagrams, and materials for experiment—all at the expense of the Turkish Government. At the conclusion of the series, the present lecturer will be followed by Salih Effendi, late President of the Pera Municipality, who will deliver a course on Natural History, and will be in his turn succeeded by Edhem Pasha, who will discourse on geology. "Shades of Amurath and Bayazid!" exclaims the *Levant Herald*, "can all this be taking place within the very shadow of St. Sophia?"

**OZONE IN CITIES.** Kosmann asserts that ozone in cities is more abundant during the night than in the day; but that where there is much vegetation, the reverse holds good. He shows that ozone is discharged from the green portions and the leaves of plants.

## Progress of Medical Science.

**ICTERUS IN PREGNANT WOMEN.** Dr. O. Saint-Vel relates that in 1858 the island of Martinique was, without appreciable cause, visited by an epidemic of jaundice, remarkable for its severity in pregnant women. It broke out at St. Pierre towards the middle of April, attained its maximum height in June and July, and terminated towards the end of the year. All races were attacked; the patients were mostly adults; no liver-complication could be detected; nor could any resemblance be traced between the disease and yellow fever. It was fatal to females only, especially during pregnancy. Of thirty pregnant women who were attacked at St. Pierre, ten only arrived at the full period of pregnancy without presenting any other symptoms than those of ordinary jaundice. The other twenty all had abortion or premature labour at the end of a fortnight or three weeks, and died in a state of coma, which appeared a few hours before or after the abortion. The females who died were from the fourth to the eighth month advanced in pregnancy. In some cases, slight delirium preceded the coma, which was never interrupted, but became more and more profound up to the time of death. Its longest duration, in two cases, was twenty-four and thirty-six hours. It was not preceded by any notable modification of the general sensibility, nor of the respiration or circulation. Hæmorrhage was absent, except in one case, where a female had it before delivery. When death was delayed till three or four days after delivery, the lochia were healthy. Almost all the children were still-born; some lived a few hours; one alone survived. None of them had the icteric colour; nor was there any sign of jaundice in the ten children who were born at full term of mothers who had had the disease. (*Gazette des Hôpitaux*, 20 Novembre 1862.)

**MECHANISM OF DISLOCATION OF THE LOWER JAW.** M. Maisonneuve has succeeded in producing dislocation of the lower jaw on the dead body, by strongly depressing the chin, pushing the condyles forward by placing the fingers behind them, and suddenly raising the jaws by means of the index and middle fingers of each hand, placed behind and under the angle, so as to imitate the action of the masseters. This plan, he says, has never failed in more than thirty instances. On dissection, M. Maisonneuve has found that the condyles are carried in front of the transverse root of the zygomatic processes, and rest on their anterior face; that the coronoid processes, completely enveloped by the tendon of the temporal muscle, are depressed below the zygomatic arches, which they scarcely ever touch, and that they oppose no obstacle to bringing the jaws together; that the capsule of the joint is much stretched, but is not torn; that the external ligament, of which the normal direction is oblique from before backwards, becomes oblique from behind forwards, and is stretched, as are also the speno-maxillary and stylo-maxillary ligaments; that the temporal muscle is elongated, but its tendon is not torn; and that the external pterygoid muscles and masseters are strongly stretched, but that the general direction of the action of their fibres is in front of the dislocated condyles, and not behind them. M. Maisonneuve found also that reduction was not facilitated by dividing the coronoid processes at their base, nor by dividing the zygomatic arches, nor by opening the capsule of the joint. On dividing merely the stylo-maxillary and speno-maxillary ligaments, as well as the posterior fibres of the external ligament, the dislocation was reduced by the slightest pressure. He believes that the difficulty of reduction depends on the fixing of the con-

dyle in front of the transverse root of the zygoma, by the passive resistance of the ligaments and the energetic contraction of the elevator muscle. He concludes hence that the best method of reduction is to gently depress the chin so as to relax the ligaments, and to push the condyles strongly back by means of the thumbs, introduced into the mouth, and resting on the coronoid processes. (*Gazette Méd. de Paris*, 8 Novembre 1862.)

**CAUSES OF OBSTRUCTION OF THE TRACHEA.** Dr. Hermann Demme arranges the causes of obstruction of the trachea under three principal heads; viz.: 1. Compression; 2. Disease of the walls of the trachea itself; 3. Foreign bodies in the tube. 1. *Compression* is generally produced by tumours of neighbouring organs, among which the most important are: Tumours of the thyroid gland—a very common cause: Tumours of the thymus gland—very rare: Tumours of the œsophagus, especially canceroid and carcinoma—very frequent: Tumours of the lymphatic glands—frequent: Tumours of the vertebral column—rare (a case is recorded by Ollivier): Congenital hygomatous cysts—rare (cases recorded by Wutzer and Hawkins): Aneurism—by no means rare; the bronchi are more frequently compressed by aneurism of the aorta, the trachea in aneurism of the carotid and arteria innominata. The occasional abnormal course of the subclavian artery between the trachea and œsophagus, producing sometimes dysphagia and difficult respiration, must also be remembered. Compression may also be produced by abscesses in the neighbourhood of the trachea, such as retropharyngeal and œsophageal abscesses, abscesses of the thyroid body, and diffuse phlegmon of the cervical muscles; by effusions of blood; or by foreign bodies, such as bullets, lying encysted between the œsophagus and the trachea. 2. *Obstruction from disease of the trachea itself* may be produced by extensive circular cicatrices, the result of tubercular ulceration, typhous processes, syphilitic ulceration, burns, and ulcers following croup. The trachea may also be narrowed by infiltration into its walls; by croupy exudation; by suppuration and the formation of abscesses around the cartilages; by necrosis of the cartilages; by diffuse thickening of the submucous areolar tissue, hypertrophy of the cartilages, and calcareous deposits, observed especially as the result of chronic catarrh; and by new formations of various kinds, such as papillary growths and polypi of the mucous membrane and submucous tissue; canceroid of the mucous membrane; and carcinoma, rarely primary in the walls of the air-tubes, but generally extending to them from neighbouring organs. 3. *Obstruction from bodies in the trachea* may be produced by foreign substances introduced into the larynx; sequestra of the cartilages detached as the result of necrosis; and croup-membranes. (*Archiv für Klinische Chirurgie*, 3 Band, 3 Heft, 1862.)

**NEW MOTOR SYSTEM OF THE HEART.** Professor von Bezold of Jena states that he has, in the course of some researches on the motion of the heart, discovered a new source of motor nerves of this organ, which connect it much more intimately and importantly than the cervical sympathetic or even the par vagum with the cerebro-spinal system. The following results were arrived at by him from experiments on animals paralysed by woorara. 1. When the pneumogastric and sympathetic nerves were divided in the neck, so as to cut off the hitherto recognised conduction of nervous influence from the central organs to the heart, irritation of the medulla oblongata produced a very marked increase in frequency of the pulse and an uncommon augmentation of the pressure of the blood in the arteries—the latter being sometimes more than doubled. 2. When, further, the spinal cord was divided in these animals at any point above the seventh cervical vertebra, the acti-

vity of the heart was almost immediately diminished: the pressure of the blood in the carotid was diminished to three-fourths, the beat of the heart became weak, and its sounds almost inaudible, etc. On the other hand, when the division was made in the neighbourhood of the third or fourth dorsal vertebra, no such effect was produced. Hence the centre of innervation does not extend below the fourth dorsal vertebra. 3. If, after dividing the cord above the seventh cervical vertebra, the medulla oblongata or the portion of the cord above the division be irritated, however violently, whether mechanically or by electricity, no change is produced in the pressure of the blood or in the frequency of the pulse. But if the portion of the cord on the distal side of the division be irritated, the blood-pressure and the heart's action, which have been diminished by the section, may be raised to or even above the normal height. Hence the motor nerves (exclusive of the par vagum and cervical sympathetic) do not come off above the seventh cervical vertebra. 4. If, in partially poisoned animals, the medulla oblongata and the peripheric portion of the divided vagi be simultaneously irritated, the results are, not an increase, but a diminution, of the pressure of the blood; not an acceleration of the pulse, but a retardation or even cessation. Bezold derives the following conclusions from his experiments. *a.* He believes he has ascertained the existence of a new central organ for the motions of the heart, having its seat neither in the medulla oblongata nor in the brain. *b.* Its fibres run through the cervical spinal cord, and pass out between the seventh cervical and fifth dorsal vertebrae. *c.* They very probably pass through the lower cervical and upper dorsal sympathetic ganglia, and enter the breast as the lower and middle cardiac nerves. *d.* This central motor organ normally furnishes three-fourths of the entire propulsive force of the heart; when it is abnormally irritated, the energy of the contractions of the heart may be increased sixfold. *e.* This cardiac nervous system, apparently having its seat in the medulla oblongata, stands in a reflex connexion with the sensory cerebro-spinal fibres. *f.* Various poisons, especially digitalis and strychnia, increase and strengthen the heart's beat, after division of the vagus, by increasing the irritability and activity of this cerebro-spinal cardiac nervous system. (*Berlin. Med. Centralzeitung*; and *Wiener Med. Wochenschrift*, Dec. 20, 1862.)

**SUPPURATIVE AORTITIS: ITS INFLUENCE IN PRODUCING PURULENT INFECTION.** M. Leudet of Rouen has published a paper on this subject, which, though the observed facts are as yet few, is of some importance. In 1829, M. Andral, in his *Précis d'Anatomie pathologique*, described an abscess existing in the coats of the aorta. The correctness of his interpretation of what he saw was, however, long doubted; and Rokitsansky suggested that a softened atheromatous deposit had been mistaken for an abscess. On the other hand, Virchow, in 1847, stated that he had been on the point of supposing an abscess to be a softened atheroma, until microscopic examination revealed the presence of distinct pus-corpuscles. In 1852, Spengler published the first case in which the clinical history had been ascertained. The patient, after exposure to cold, had subacute articular rheumatism; then, after being again exposed to cold, he had general symptoms of thoracic and cardiac inflammation, followed by symptoms of purulent infection. At the *post mortem* examination, there was found to be ulcerative endocarditis, with an abscess between the coats of the aorta opening into the heart. In 1856, Dr. Schutzenberger communicated to the Strasburg Medical Society the history of a man who was recovering from pneumonia of the left lung, when he was attacked with violent rigors occurring at irregular intervals, copious sweating, and a peculiar yellow tint of the skin and sclerotic. At the autopsy, an abscess of the size of a

nut was found, which had formed between the external and middle coats of the aorta, and opened into that vessel. M. Leudet has also observed a case similar to those related by Spengler and Schutzenberger. In all three, abscess was at the origin of the aorta; but this is not always its seat, for M. Leudet refers to two cases noticed by Rokitsansky and Lebert, where the collection of pus was higher up in the vessel. Suppuration may also, in place of being idiopathic and primitive, be a consecutive result of the deposition of atheroma. In the cases collected by M. Leudet, the pus was collected in a small cavity in the external cellular coat, and was infiltrated into the middle elastic coat. These two coats, especially the external, presented marked vascular injection. Fine capillary vessels sometimes extended into the thickness of the middle coat, but never reached the inner coat, which most generally was not at all coloured. In no case were false membranes or clots observed at the level of the inflamed artery. The pus presented the ordinary characters of this secretion. The large opening by which the abscess communicated with the vascular canal had no doubt introduced a small quantity of pus into the blood during life. The existence of pyæmia was denoted by the simultaneous presence of abscesses in the liver, lungs, spleen, etc. In M. Leudet's patient, there was meningitis; in Rokitsansky's case, abscess of the spleen; and Spengler's patient had hypostatic pneumonia. The study of the symptoms of suppurative aortitis is rendered very difficult by the coincidence of numerous lesions, which may mask the peculiar symptoms of the disease. The first stage of the disease is one of inflammation, probably simply exudative, of the coats of the vessels or of the heart. This inflammation is generally intense, as appears from the results of *post mortem* examinations. It is that form of endocarditis which M. Bouillaud terms phlegmonous, in opposition to superficial; he compares the first to phlegmonous, and the second to simple erysipelas. Nothing in the symptoms of the cases appears to have led to the suspicion of so intense an inflammation. After the manifestation of symptoms which may be supposed to denote the presence of exudative inflammation, there is a kind of remission, which is, however, far from constituting complete convalescence. These symptoms of purulent infection set in—especially rigors. This symptom may lead to a diagnosis, when no inflammation can be discerned elsewhere, especially in the venous system. (*Archiv. Génér. de Méd.*; and *Gazette Méd. de Paris*, 20 Decembre 1862.)

**PNEUMONIA FOLLOWED BY ABSCESS IN THE LUMBAR REGION.** Dr. Brandicourt of Amiens relates the case of a young woman aged 22, who in April 1861 had an attack of pleuropneumonia followed by empyema of the left pleura. In July, she was attacked with severe pain in the left renal region; and at the end of August, a swelling appeared at the outer part of the spine on the left side, two finger-breadths above the crest of the ilium. Fluctuation was not distinct, but there was a pasty feeling under the finger. The patient had an obstinate cough, and expectoration was very copious. In the middle of September, Dr. Brandicourt opened the swelling, by plunging in a bistoury to the depth of nearly two inches. A very large quantity of serous pus, of good colour, immediately escaped; the flow being influenced by the respiratory movements, and resembling the jet of an intermitting fountain. The discharge, which amounted to three litres, was partially restrained by closing the aperture; and on auscultation, the respiratory murmur in the lung, which had not been heard during several months, was detected. The pus continued to be discharged during a month, during which time the patient had rigors every evening, and became very weak. Under the use of tonics, including quinine, the rigors disappeared; the suppuration gradually dis-

appeared; and by the beginning of November the left lung was discharging its functions nearly as well as the right. In a short time, the patient recovered perfectly. (*Gazette des Hôpitaux*, 21 Octobre 1862.)

## British Medical Journal.

SATURDAY, FEBRUARY 7TH, 1863.

### THE ATTEMPT TO CONVERT A PRIVATE CHARGE INTO A PUBLIC SCANDAL.

DR. BURROWS was last year elected President for the year of the British Medical Association. By accepting the office he committed an unpardonable mistake or crime in the eyes of the *Lancet*. Whether it be *post hoc* or *propter hoc* of this presidency—our readers may judge for themselves—it is a fact that, for the last three weeks, Dr. Burrows has been prominently introduced into the pages of that journal, under the heading of “Alleged Consultation with a Homœopath”. Carefully abstaining from making any direct accusation against our President, the *Lancet*, with the true spirit of Tartuffe, has quietly allowed (with a sort of “I could now an’ if I would” language) the idea to go forth to the profession that there was some actual truth in the accusation. Having, however, striven its best during three weeks to find out, if not overt, some kind of constructive treason; and, having utterly failed in its respectable efforts, the *Lancet* now admits with the worst of grace, and forced by the strength of facts, “that in many respects the letter of Dr. Burrows is satisfactory”; which, being put in plain language, means that “we admit the charge brought through us against Dr. Burrows, and which for the last three weeks we have been carefully fomenting, is without foundation in fact; we admit that Dr. Burrows did not knowingly meet a homœopath in consultation.” In this way the *Lancet* characteristically withdraws the charge which it has published, which it has manifestly patronised, and which it cannot sustain.

Our readers will remember that we dealt with this case as we have dealt with every other of the kind which has been brought under our notice. We have never allowed such a grievous imputation to appear in our pages, unless the evidence in our hands was clear and unmistakeable. In this case, when the statement was brought under the notice of Dr. Burrows, he positively denied that he ever, to his knowledge, had met a homœopath in consultation. Dr. Burrows is a man of honour; and we willingly took his word that, in meeting this man at Bedford, he did not know he was meeting a homœopath. More than this: we showed his letter to two of the hospital medical officers at Bedford, and both expressed their belief that Dr. Burrows had not

knowingly met the homœopath. Under such circumstances, and in the absence of any evidence to the contrary, to have introduced the incident week after week into print, and to have tacitly allowed the reader to think we believed in the truth of the charge, would have been, in our opinion, simply the fomenting of a gross scandal. Had we done this, we might have very fairly laid ourselves open to the charge of having made use of the pages of this JOURNAL for the purpose of gratifying private malevolence.

Such is our opinion. The *Lancet* thinks otherwise; and in order to cover its retreat from a false position, and annoyed at the discovery of the mare’s nest over which it has been three weeks brooding without hatching, it cannot retire without its usual *mud-fling* at this JOURNAL.

Let the members of the Association hear from the high-toned morality of the *Lancet* what sort of a JOURNAL they possess, and what sort of honour and honesty presides over its management. “In the following week,” says Tartuffe’s organ, “the servile print which disgraces the honourable Association of which he is President bent itself in adulation, and declared naïvely that it had determined, if possible, to avoid all public allusion to the matter,” and that the charge “was made under an utter misunderstanding of the facts of the case.” Here Tartuffe has surely overdone it: we mean his old game of praising the Association and abusing its JOURNAL. Is it logical to say that an Association can be *honourable*, whose JOURNAL is *servile*? At all events, we are now taught by the mouthpiece of the *Lancet* that to act according to the ordinary principles of honour and of charity, which are supposed to guide the intercourse of gentlemen and members of the profession, is to perform an act of disgraceful servility. We must leave our readers to form their own comments on the character of their JOURNAL, and on the morality of the *Lancet*; remarking only that we will not, until assured of the fact, believe that the lines referred to were penned by any member of the medical profession.

Let us recapitulate the facts of the case. Dr. Burrows is summoned to Bedford by a gentleman who, it turns out, is notoriously (in Bedford) a practitioner of homœopathy. He meets him in consultation with the physician of the infirmary there. Dr. Burrows has not the slightest idea of this person’s homœopathic principles; not a word thereon is insinuated to him by the local physician, who must have been well aware of the fact, and whose silence on the occasion is inexcusable. The patient is treated, not homœopathically, but medically; not one word of the globalistic method is suggested or thought of in the consultation. Throughout the whole affair, Dr. Burrows is free from the very smallest imputation of having dealt knowingly,

either directly or indirectly, with homœopathy or its practisers. But now steps in Don Basilio, calumniator in chief, and *insinuates* that Dr. Burrows must have known that he was dealing with the thing, because this very person's claim for registration under the Medical Act came under the consideration of the Medical Council on an occasion when Dr. Burrows was himself in the chair. Now to this allegation Dr. Burrows's answer is most explicit: "I certainly did not remember that the name of Coombs was among those who had applied to be registered on diplomas granted by a homœopathic college; and even if I had remembered that name, I should not have suspected that it was that of a former pupil, who, as I have elsewhere stated, has frequently requested me to prescribe for his patients on principles diametrically opposed to homœopathy." Dr. Burrows assures us that he had not the slightest recollection that the man whom he met at Bedford had ever applied to be registered as an M.D.; and that, even if the name of the man who sought the registration in 1860 had come across his mind, he would not have had any suspicion that it was the name of him at Bedford, who was his former pupil, and who had previously sent him patients to be treated medically. And it is well to remember that this Medical Council meeting took place two years and a half ago.

This is the answer which Dr. Burrows gives to the *Lancet*, who has furbished up the scandal; and who says: "It is for Dr. Burrows to explain this striking discrepancy." Dr. Burrows has, we will venture to say, given an answer which will be accepted by every member of the medical profession. But how does Don Basilio receive the reply to the question which he asked? He asked it insinuatingly, and he receives the reply insinuatingly. Like his prototype, the *Lancet* could neither boldly nor truly bring the accusation; he produced it obliquely. And now, when the positive denial has come, true to his character, he admits, from the very force of the facts, that "Dr. Burrows's letter is in many respects satisfactory," and then proceeds to accept the explanation exactly as he made the accusation, insinuatingly and obliquely. And this is the journal which, not many months ago, actually threw its shield over and bedaubed with the most fulsome flattery a gentleman who avowed that he met homœopaths in consultation, and openly defended the practice! No; it is not true to say that Dr. Burrows's answer is "in many respects satisfactory." His answer is not satisfactory unless it is completely so. Either the accusation is true or it is false. But it has been proved to be utterly devoid of all foundation, and, therefore, the answer is wholly satisfactory. As such, we are sure, notwithstanding all the artifices of Don Basilio, it will be received by the profession at large.

We, of course, do not for one moment wish it to be understood that any blame in this matter is to be attributed to the gentlemen who brought this question under the notice of the medical press. We think, on the contrary, they only did their duty in so doing; and we are satisfied that no persons will be more gratified than they to have their doubts cleared up as they have been by Dr. Burrows's emphatic answers.

#### CHOLESTERINE: ITS PHYSIOLOGICAL AND PATHOLOGICAL IMPORT.

CHOLESTERINE is a product of the animal body regarding which, though it is found in sufficient abundance, and the localities in which it exists are tolerably well determined, physiologists have as yet failed in ascertaining precisely where it arises, or what becomes of it, or whether it has any pathological importance beyond its frequent presence in gall-stones. Thus, Longet, writing in 1861, says that "it is one of the products destined to be expelled from the economy"; but in what manner he does not attempt to shew. Robin and Verdeil also speak of its physiological import as altogether unknown; and, not to quote more instances, our physiological treatises in general are equally deficient of information on more than the existence and locality of this substance.

Dr. Austin Flint, junior, of New York, has made some observations in order to clear up the unsettled points relating to this substance, and has published his researches, with the results at which he has arrived, in the October number of the *American Journal of the Medical Sciences*. He has examined cholesteroline in its relations with seroline, a substance found hitherto occasionally in small quantities in the blood, but which Dr. Flint discovers to exist normally in fæces, and which he therefore calls *stercorine*. He holds that these two substances—cholesterine and seroline or stercorine—have a direct relation to each other; that the knowledge of this relation is likely to be of great pathological as well as physiological importance; that, in fact,

"What the discovery of the function of urea has done for diseases which now come under the head of uræmia, the discovery of the function of cholesteroline may do for the obscure diseases which may hereafter be classed under the head of cholesteræmia."

The general facts that cholesteroline is found in the bile, brain, liver, brain and nerves, and also in the crystalline lens, meconium, and (occasionally) faecal matter, and that it is eliminated by the liver, being recognised, Dr. Flint applies himself to the examination of the question: Where is the substance formed? Its principal seats being the liver and the nervous system, he has endeavoured first to determine whether it is formed or merely deposited in the brain and nervous system, by making comparative analyses of arterial and of venous blood. His results, in six

experiments on animals, shew a marked increase of cholesterine in the blood of the internal jugular vein, and also an increase in the blood returning by the femoral vein, as compared with the blood of the carotid artery. He infers hence that the cholesterine is produced in the brain and absorbed therefrom by the blood; and, since the increase in the blood of the jugular vein can only have come from the formation of cholesterine in the brain, he argues, supported by the known results of chemical analysis of the tissues, that the cholesterine found in the general venous system must be produced in the nerves.

To further confirm this theory, he has analysed blood taken from each arm of three patients suffering from hemiplegia; the result being that on the sound side the blood yielded from 0.481 to 0.808 parts of cholesterine per 1000; while on the paralysed side not a trace could be found.

Dr. Flint has also made analyses of the blood of the portal and hepatic veins, as compared with that of the carotid artery. He finds in them proof that cholesterine is eliminated by the liver; and that, apparently, the diminution of cholesterine in the blood of the hepatic vein is nearly equal with the increase of this substance in the blood that has passed through the brain. Hence he sees in the bile two important elements having separate functions.

"1. The bile contains the glycocholate and taurocholate of soda; which are not found in the blood, are manufactured in the liver, are discharged mainly at a certain stage of the digestive process, are destined to assist in some of the nutritive processes, are not discharged from the body, and, in fine, are products of secretion.

"2. It contains cholesterine; which is formed in the blood, is merely separated from it by the liver, and not manufactured in this organ, is not destined to assist in any of the nutritive processes, but merely separated to be discharged from the body, and is a product of excretion."

At this point, Dr. Flint takes up the examination of the hitherto undetermined question: What becomes of the cholesterine after it has been discharged from the liver?

Cholesterine has been said by several authors on physiology and physiological chemistry to be present in fæces. Dr. Marcet, however, has noticed its absence; and Dr. Flint's analyses lead him to the same conclusion. Convinced, however, that the substance must be discoverable in some shape, he has, by treating dried fæces with ether and alcohol, etc., obtained a substance in the form of delicate transparent needles, having all the characteristics of seroline. This substance being found in large quantities in the fæces, he terms *stercorine*. It is not, according to him, the same substance as that which has been described by Dr. Marcet under the name of *excretine*.

The observations which Dr. Flint has made in regard to stercorine are as yet incomplete; but he brings forward the following evidence to show that it is a result of a change of the cholesterine during

the digestive process. Cholesterine is found in the meconium, where stercorine is absent. This arises from the fact that bile is formed long before any food is taken into the alimentary canal, and before the intestines have had an opportunity of performing their digestive function. As soon, however, as digestion is established and the digestive fluids are secreted, the cholesterine is lost, and stercorine appears in the excrements. In hibernating animals also, cholesterine is found in the fæces during the period when no food is taken, but disappears when the animal awakes and takes food. Again, normal fæces do not contain cholesterine; but, by examining the discharges of fasting animals, Dr. Flint has succeeded in finding small quantities of cholesterine in conjunction with the stercorine. Hence he infers that the change of cholesterine into stercorine is evidently connected with the digestive process.

The effect of cutting off the supply of bile from the intestines on the presence of stercorine in the fæces has been noticed by Dr. Flint in the case of a patient who had jaundice from duodenitis. The fæces were clay-coloured for a time; and, on examination, no cholesterine nor stercorine could be found in them. Nineteen days afterwards, when the fæces had regained their normal colour, they were again examined; and 0.34 of a grain of stercorine was found in 502 grains.

Further, the theory of the conversion of cholesterine into stercorine is supported, according to Dr. Flint, by the fact that the amount of stercorine found in the fæces corresponds very nearly with the calculated average amount of cholesterine discharged from the liver.

Regarding the pathological relations of cholesterine, Dr. Flint promises more complete observations than are contained in his present paper. So far, however, as his investigations have gone, he has arrived at the conclusion that the retention of cholesterine in the blood is liable to produce a train of symptoms of blood-poisoning, which he designates *cholesteræmia*. He explains in this way the difference in the gravity and fatality of the symptoms of two forms of jaundice; one being attended only with yellowness of the skin, and dependent merely on the retention of the bile in the excretory passages, and the absorption of its colouring matter; while in the other the cholesterine is retained in the blood. In the former case, that of simple jaundice, such as that depending on duodenitis, the amount of cholesterine in the blood is not necessarily increased; while in jaundice connected with structural change, as cirrhosis, the increase over the average maximum in healthy blood has been found by Dr. Flint as high as 146 parts in 1000.

The morbid condition which Frerichs terms *acholia* is explained by Dr. Flint on the theory of the retention of cholesterine. In it there may or may not

be jaundice; but, as described by Frerichs, the patients may "become unconscious, and be afterwards seized with noisy delirium, from which they pass to deep coma, and in this state die." In one case observed by Frerichs, there was "spasmodic contraction of the muscles of the left side of the face." In such cases, attempts have been made to discover the elements of the bile—biliary acids and pigment—in the blood; it being argued that they ought to be accumulated in this fluid in the same way as urea in uræmia. Yet, as has been shown by Frerichs and Moleschott, they have not been found. Dr. Flint suggests, however, that if search had been made for cholesterine, the result would have been different. As regards this acute form of jaundice, Dr. Flint has not had an opportunity of actually determining the retention of cholesterine; although the analogy of the symptoms referrible to the nervous system with those found in cases of cirrhosis, where the retention of cholesterine has been ascertained, is strongly marked.

The degree to which cholesterine may be retained, and the quantity of stercorine in the feces correspondingly diminished, varies in cases of cirrhosis with the amount of structural disease. If the liver be but partially affected, the symptoms of cholesteræmia may be slight or absent; for the same reason that the function of the kidneys may be partially interrupted without producing symptoms of uræmia.

These researches of Dr. Flint, of which we have given an outline, and which we hope he will extend, are apparently of considerable importance. They seem to show that, physiologically, cholesterine bears the same relation to the liver and bile as urea does to the kidneys and urine; and that, pathologically, the retention of cholesterine in the blood produces a train of symptoms designated by Dr. Flint as *cholesteræmia*, which may be compared with those resulting from the retention of urea—uræmia. Finally, as Dr. Flint observes:

"When we add to these conditions the cases of what is ordinarily called biliousness, attended with drowsiness, an indefinite feeling of *malaise*, constipation, etc. (and all this relieved by a simple mercurial purge, which is said to promote the secretion of the liver), cannot we hope that some light will be shed on their pathology by a knowledge that there is a condition called cholesteræmia? As yet this is but speculation; but the discovery of the important function of cholesterine opens an almost boundless field of inquiry in this direction; and ere long the physician may talk of 'biliousness' and 'liver-complaint' with some definite ideas of their pathology."

Here for the present we leave Dr. Flint and his researches. If at a future time he should continue and publish his observations, we will endeavour to lay them before our readers. What he has already laid before the profession on the subject of cholesterine, we commend to the careful attention of British physiologists and chemists, and practical

physicians; in order that they may test for themselves how far the observations of our able American *confrère* are trustworthy, and his conclusions sound.

### GRATUITOUS MEDICAL SERVICES.

WE have already pointed out the great use of "cottage" village hospitals, and the peculiar services which they are capable of affording to the sick and wounded of the district wherein they are located. It is very probable that the one which has already succeeded so well at Cranley may be the model for the construction of many similar ones throughout the country. We have, in fact, received a circular announcing the intention of establishing a "cottage" hospital at East Grinstead; and we, therefore, at once strongly urge upon the consideration of the medical men who may be attached to such hospital the most important question of gratuitous services. In the plan which lies before us, one part of the programme is, that the medical officer is to "give his professional services gratuitously"; and, in fact, we gather from the circular that here, as in like cases, the chief promoter of the scheme is a member of our profession. Now we would ask that gentlemen to tell us what are the grounds upon which he thus tenders his services gratuitously. He may answer, that he is only doing like all the rest of the professional world; and truly it is not with any idea of blaming him that we ask the question. Our wish is to try and arrest an evil which is ruining and degrading our profession; and to prevent, if possible, its extension into this new field of competition which appears opening before us. We simply ask this: Can any gentleman, who gives or offers these public services gratuitously, adduce one single reasonable argument in favour of the suicidal folly, as we must, in the meantime, be permitted to call it. Here are the Medical College and many medical benevolent funds continually ringing in our ears the direst tales of distress and misery falling upon members of our profession. Continually, also, we have loud complaints of the miserable receipts of the hard-worked and over-worked surgeon; and yet daily do we continue and extend this mad system of doing the work of the community gratuitously. Does the lawyer ever do one stroke of public business without pay? Where is the highly educated, experienced, and wealthy vicar, dean, or bishop, who does regular gratuitous public work in a hospital? Do the surveyors of our public medical charities survey gratis? Do wealthy contractors lay their bricks gratis? Do butchers supply the hospital sick with beef gratuitously? Is there one single class of persons in this country, from the Queen down to the scavenger, who do public work gratis, except medical men? Undoubtedly not. To us alone belongs the silly, thankless palm of performing public work—the work

of the community at large—without pay and without thanks. Nay, more than this: we actually go down on our knees and ask the public permission to do this work.

Let it be remembered, the system is one of modern invention; it was begotten by selfishness, out of competition. It was no love of doing the heaven-work of pure charity which presided over, and which still presides over, its existence. We would, therefore, earnestly ask the medical supporters of these cottage hospitals to pause before they assist in the extension of this absurd system of professional spoliation.

#### THE "POMMADE DIT HOLLOWAY."

"PROFESSOR" HOLLOWAY has gained the day against his agent, Mr. Sellen. The court has decided that Mr. Sellen did not obtain from the French Government the permission required by the "Professor," and was, therefore, not entitled to his pay. "Professor" Holloway agreed to pay the agent £500 if he could obtain him permission to sell Holloway's Ointment in France and her colonies. By the French law, which prohibits the sale of secret remedies, that could only be done by permission of the Minister of the Interior. Holloway's Ointment was a secret remedy, and was so treated. To obtain a patent for it, it had been treated as a cosmetic and called a "pomade," and as the analysis showed that it contained only butter, lard, turpentine, and wax, the French had laughed at it, and said there was nothing noxious in that, it might be sold as a "pomade."

But even the patent to sell the "pomade dit Holloway" was worthless; for when offered to the defendant by the plaintiff it was long after it had been granted, and when it had become void though the non-payment of certain fees.

Who in future will venture to say that a "rose by any name would smell as sweet"? Here is the famous invention which as "Holloway's Ointment" is a "sovereign remedy," and which as "Pomade dit Holloway" is an unsaleable article. A part of the "court," it is worthy of note, in the shape of Justice Williams, could not let slip the occasion of bringing under the notice of the public at large an excellent application,

"Mr. Justice Williams said he should be ungrateful if he did not express his obligations to the *pomade* known as *Pomade Divine*, from which he had frequently obtained benefit."

The "Justice" did not (as he should have done) tell the public whether it was from the application of the "pomade" to his skin or to his wig that the benefit resulted. We trust the proprietors of the divine pomade will not fail to thank Mr. Justice Williams, and have his words and name distributed over the surface of the earth on the backs of their ointment-pots.

#### THE WEEK.

OUR attention has been called to the following announcement in a country paper, and from the statement made at another page we cannot doubt as to its general correctness. We sincerely trust that if the manifest evil done in the present case is irremediable, the fact may lead to the prevention in future of such unwarrantable exercise of power. It seems to us that the gift of the appointment ought to be placed in more responsible hands than in that of a Government Inspector of Factories; and we should strongly recommend those gentlemen who are moving in this case to apply also to the Home Secretary to have the gift of the appointment placed in more fitting hands. We read in the *Oldham Standard* as follows:—

"We are informed that the office of government medical officer for the factories for this district, vacant by the death of Dr. Earnshaw, has been conferred on Mr. Coles, the son of Mr. Coles, the government sub-inspector of factories. Mr. Coles is quite a young man; and has scarcely had any experience in his profession to warrant his appointment to such an important office. It is one of the worst pieces of jobbery perpetrated here for some time; and we understand that the medical gentlemen in the town very properly intend memorialising Sir George Grey on the subject. Surely youth and inexperience ought not to be preferred to age and merit."

SIR E. B. LYTTON, as some of our readers may remember, last year insulted the common sense of the British people by the publication, in *All the Year Round*, of a Mesmeric tale. The fanciful baronet did this, we must suppose, for the purpose of puffing his favourite science—the Mesmeric. We are not surprised, therefore, to find that a journal which could admit such transcendental nonsense into its pages should also admit a fling at "illiberal doctors"—the illiberal doctors being those who refuse to meet homœopaths in consultation. Having exalted the virtues and miraculous powers of Mesmerism, naturally enough *All the Year Round* would defend the high priests of the art, even though at the expense of the medical profession. In its current number, it in fact thus abuses a resolution of the Dublin College of Surgeons, for the purpose of praising the epistle of his Mesmeric Grace the Archbishop of Dublin. One can only deplore the illogical ignorance which could dictate the insertion of such a paper in a journal of such pretensions, and may fairly suppose that the great defender of the faith, Sir E. B. Lytton, had a finger in its construction. If so, we wish the homœopaths joy of their new friend.

THE Royal College of Physicians has refused to entertain the subject of the matter in dispute between Dr. Tweedie and Dr. Murchison.

THE *Chemical News*, in speaking of the cleanliness of the process pursued by Messrs. Stevens in their bread making, winds up with the following excellent bit of advice, which we recommend to the consideration of all honourable purveyors of sound articles of food and physic :—

"In conclusion, let us advise the company most strongly to have nothing to do with testimonials from the numerous adulteration-mongers, from whom, we have no doubt, they have long since received applications to analyse their bread. If their bread is good—and the samples we have tasted were excellent—the public will soon find it out, and bestow on them the best of testimonials, a large trade; while fulsome letters from half-a-dozen 'chemical and microscopical analysts,' with half the alphabet added to their names, can only bring suspicion on their wares, and make sensible people chary of dealing with them. If 'good wine needs no bush,' what shall we say of that still greater rarity, good bread? The company has commenced in a spirited and dignified manner, without puff or flaming advertisements. Let them go on so, and we venture to prophesy that their household loaves will soon become 'household words.'"

## Association Intelligence.

### NOTICE REGARDING NEW MEMBERS.

By desire of the Committee of Council, the General Secretary requests that the Local Secretaries will be good enough to forward to him the names of all New Members who join the Association through the Branches; as otherwise the JOURNAL cannot be sent to them.

PHILIP H. WILLIAMS, M.D., *General Secretary.*

Worcester, November 10th, 1862.

### BRANCH MEETING TO BE HELD.

NAME OF BRANCH.	PLACE OF MEETING.	DATE.
SHROPSHIRE SCIENTIFIC. [Annual.]	George Hotel, Shrewsbury.	Friday, Feb. 13th, 2.30.

### NORTH WALES BRANCH: GENERAL MEETING.

A GENERAL meeting of this Branch was held on Tuesday, January 27th, at 1.22 p.m., at the Dudley Arms Hotel, Rhyl, under the presidency of Dr. G. TURNER JONES of Denbigh. There were also ten other members present. Several letters were received from members, regretting their inability to attend.

*Annual Meeting.* It was unanimously resolved that the annual meeting of the members of this Branch be held on Tuesday, the 7th of July next, at 1 p.m., at the Royal Hotel, Rhyl.

*Papers.* The following papers and cases were communicated, and elicited a long and interesting discussion.

1. Diphtheria, followed by Ascites and Recovery. By T. E. Jones, Esq., Llanasa.

2. Case of Retention of Urine. By L. Lodge, L.R.C.P. Ed., St. Asaph.

3. Case of Occlusion of Vagina and Anus. By J. C. Davies, M.D., Holywell.

4. Case of Hermaphrodite. By J. Williams, Esq., Holywell.

The members afterwards dined together, and passed a pleasant and agreeable meeting.

### METROPOLITAN COUNTIES BRANCH.

*Gratuitous Medical Services.* At a meeting of the Council of this Branch, held on February 3rd, the following proposals for the restriction of the system of gratuitous medical services were approved, and ordered to be published in the JOURNAL.

1. To give publicity to all hospitals and dispensaries that recognise the principle of payment for medical services. (This has done good service in the case of the insurance companies.)

2. To append to every medical vacancy announced in the JOURNAL the amount of salary or honorarium, if any, that is attached to the post, just as the value is given with every clerical vacancy.

3. To bring from time to time the expediency as well as the justice of paying for medical, no less than for legal and clerical services, under the consideration of the governors and committees of all institutions.

*New Members.* The following gentlemen, residing in the Metropolitan Counties district, have been duly elected members of the Association, according to Law xiv, at meetings of the Council of this Branch held on January 13th and February 3rd.

Atkins, Jas. R., M.D., Grove House Asylum, Stoke Newington Green  
Barker, Alfred J., M.D., Upper Holloway  
Blackstone, Joseph, Esq., Gloucester Road, Regent's Park  
Bridgeman, George W., Esq., 73, Margaret Street  
Bryant, Thomas, Esq., Assistant-Surgeon to Guy's Hospital, Finsbury Square  
Burrows, William A., Esq., Quadrant Villa, Islington  
Cahill, Thomas, M.D., Albert Terrace, Knightsbridge  
Challice, John, M.D., Great Cumberland Street  
Clark, Alfred, Esq., Twickenham  
Clark, Andrew, M.D., Assistant-Physician to the London Hospital, Montague Street, Russell Square  
Clark, F. Le Gros, Esq., Surgeon to St. Thomas's Hospital, St. Thomas's Street  
Dixon, Thomas, M.D., Porchester Place, Bayswater  
Dow, John, Esq., St. Martin-le-Grand  
Edwards, D. O., Esq., Giltston Road, Brompton  
Eyles, Richard S., Esq., St. Andrew's Court, Holborn  
Forbes, John Gregory, Esq., Devonport Street, Hyde Park  
Forsyth, John, Esq., C.D., late Bengal Medical Service, Oriental Club  
Galton, Robert Cameron, M.D., Harley Street  
Gibson, John R., Esq., Surgeon to Newgate Prison, Russell Square  
Grant, Alexander, Esq., late Bengal Medical Service, Park Road, Haverstock Hill  
Hawkins, Francis, M.D., Registrar to the Medical Council, Bolton Street  
Hayward, Henry H., Esq., Queen Anne Street  
Headland, Edward, Esq., Upper Portland Place  
Holt, Barnard, Esq., Surgeon to the Westminster Hospital, Savile Row  
Hunt, Alfred, Esq., Hammersmith  
Kisch, Joseph, Esq., Circus Place, Finsbury  
Kitching, George, M.D., Enfield  
Langmore, John C., M.B., Oxford Terrace  
Latham, Peter M., M.D., Grosvenor Street  
Leared, Arthur, M.D., Physician to the Great Northern Hospital, Old Burlington Street  
Lee, Newton B. C., Esq., Talbot Terrace, Westbourne Park  
Mackmurdo, Gilbert, Esq., F.R.S., Surgeon to St. Thomas's Hospital, New Broad Street  
Mapleton, Henry, M.D., Inspector General, Army Medical Department, Whitehall Yard  
Mushet, William B., M.B., Fulham  
Norton, Robert, M.D., Westbourne Grove West  
Pearse, George, L.R.C.P. Ed., Regent Street, Westminster  
Phillips, Richard, Esq., Leinster Square  
Randall, John, M.D., Medical Officer to St. Marylebone Infirmary, Portman Street  
Rendle, James Davy, M.D., Medical Officer to the Government Convict Prison, Brixton Hill  
Rose, Henry Cooper, M.D., Hampstead  
Russell, William A., L.R.C.P. Ed., St. Alban's  
Sankey, William H. O., M.D., Asylum, Hanwell  
Skey, Frederick C., Esq., Surgeon to St. Bartholomew's Hospital, Grosvenor Street  
Slyman, William D., Esq., Wellington Road, Kentish Town  
Smith, Thomas, Esq., Demonstrator of Anatomy at St. Bartholomew's Hospital, Montague Street  
Smith, William A., M.D., Physician to the City Dispensary, Doughty Street  
Spitta, Robert J., M.D., Medical Officer to the Clapham Dispensary, Clapham Common  
Stone, Thomas A., Esq., Grosvenor Street  
Witten, Edward W., Esq., Gibson Square

## Reports of Societies.

### MANCHESTER ROYAL INSTITUTION: MEDICAL SECTION.

DEC. 3, 1862.

L. BORCHARDT, M.D., in the Chair.

*Iridectomy.* Mr. THOMAS WINDSOR exhibited a case in which he had performed iridectomy, chiefly with the view of showing how beautifully the ciliary processes were displayed.

*Encephalocele.* Dr. LORIMER exhibited a case of encephalocele evidently protruding from the occiput, and about which he purposed making some future remarks.

*Rupture of the Uterus.* Dr. THOMAS exhibited an uterus ruptured transversely across the fundus. The pelvis was slightly contracted; and ergot had been given by a homœopathic practitioner.

*Diabetes Mellitus.* The debate on Dr. Noble's paper was resumed, and was of considerable interest. Dr. J. O. Fletcher, Dr. Roberts, Mr. Greaves, Dr. Edward Smith of London, and others, took part; and the opinion that there is at any rate a practical distinction between certain classes of diabetes was generally maintained.

*Medical Diary.* Dr. BARLOW read a narrative of a voyage to Australia and back in the *Donald McKay*. It was of much interest, and abounded with practical hints suitable for various emergencies.

ANNUAL MEETING, JANUARY 14TH, 1863.

L. BORCHARDT, M.D., in the Chair.

*Report.* The annual report was read and approved of. It showed that the society was never in a more flourishing condition as regards numbers or general activity; but regretted the gradually increasing financial difficulties; and suggested that to meet these, as well as to increase the attractiveness of the library, it was advisable to raise the annual subscription.

In accordance with this suggestion, it was afterwards resolved that the subscription for town members be increased to two guineas.

*Office-bearers and Committee.* The following gentlemen were then elected office-bearers:—*President*, E. Lund, Esq.; *Vice-President*, Dr. D. Noble; *Treasurer*, Dr. Borchardt; *Honorary Secretary*, Dr. W. Roberts; *Honorary Treasurer*, Thomas Windsor, Esq.; *Honorary Editor*, Dr. J. Thorburn. *Committee*, Dr. Alcock; M. K. Day, Esq.; G. Greaves, Esq.; Dr. Medd; Thomas Mellor, Esq.; Dr. Samelson; Dr. W. Skinner; R. B. Smart, Esq.; Dr. Stone; Dr. Thomas; Dr. Thorburn; J. Windsor, Esq.

### EPIDEMIOLOGICAL SOCIETY.

MONDAY, DEC. 15TH, 1862.

CHARLES MURCHISON, M.D., in the Chair.

REPORT ON THE STATE OF EPIDEMIC DISEASE IN GREAT BRITAIN IN 1861-2. BY J. N. RADCLIFFE, ESQ.

THE Report referred to the twelve months ending the 30th September 1862. The following is a recapitulation of some of the principal facts recorded.

The health status of the English population, as estimated from the unusually low rate of mortality throughout the year, was generally good, notwithstanding dearth of provisions and an excessive amount of pauperism. The health status of the Scottish population was markedly below the average, as shewn by the large amount of sickness prevalent in the last quarter of 1861, and the high rate of mortality since the commencement of 1862.

The average death-rate of Scotland, it is well to remark, is below that of England. Thus, during the six years 1855-60, the annual proportion of deaths in England was 219 per 10,000 population; during the same period in Scotland, the proportion was 208.

The high range of temperature in the winter months and low range during the summer, in England, exercised a favourable influence over the health, notwithstanding much wet and variability of weather. In Scotland, similar conditions of temperature and weather existed, but to an exaggerated extent; and the great changes which were experienced, and especially the undue humidity of the atmosphere, were apparently the fostering causes of the influenza and throat-affections, which appear to have been more common there than in England.

The epidemic diseases most prevalent in England were continued fever, scarlatina, measles, diphtheria, whooping-cough, and small-pox. In Scotland, the same diseases, with the exception of small-pox; also, and more particularly, sore-throat, often assuming a diphtheritic character, and accompanied by diphtheria, played the chief part in the epidemiology of the twelve months.

In both parts of the kingdom, continued fever prevailed most commonly in the autumn quarter of 1861; and in England, the affection would appear to have been more general in the northern than in the southern portion of the kingdom.

In both countries, *scarlatina* was widely prevalent in the northern districts in the last quarter of 1861; but the disease became more active in the southern districts in the third quarter of 1862.

Measles prevailed extensively, and in some instances very fatally, in the winter quarter in England. In Scotland, the disease appears to have been most prevalent in the spring and summer quarters.

Diphtheria was, in England, principally fatal in the autumn quarter; but the disease prevailed more or less in every registration district during the year. In Scotland, the disease, together with sore-throat, appears to have been epidemic throughout the year.

Whooping-cough was widely prevalent in England during the winter quarter; in Scotland, during the winter and spring quarters.

Influenza was epidemic in Scotland in the autumn and winter quarters.

Finally, small-pox broke out in many districts of England, but more particularly in the eastern and south-western and northern counties, and in Yorkshire.

In no instance did an outbreak of any of the different diseases referred to, as occurring in England, assume what may be termed general proportions. The outbreaks were essentially local. But the dispersion of the various maladies, or of their centres of manifestation, over the kingdom; the cropping out of exaggeration of these diseases in different localities; and the effects they apparently exercised upon the sickness and mortality of certain districts, without heightening the death-rate of the whole kingdom, present a study of great interest. From this study, it is reasonable to conclude that, in dealing with these local outbreaks of epidemic disease in ordinary periods, the best chance is afforded of warding off the wide spread and more deadly outbreaks of extraordinary periods.

The detailed mortuary returns for Scotland extend as yet only to the year 1857; but the returns for England are brought down to 1860. From the latter, then, may be obtained information as to the status of the several epidemic diseases most prevalent in the twelve months discussed, immediately prior to that period.

Since 1857, the mortality from continued fever has slowly declined. In that year, the deaths from this cause amounted to 19,016; in 1860 they were 13,012.

In 1855, the mortality from scarlatina was 17,314. In 1856 and 1857, the number of deaths from this dis-

ease fell considerably—the mortality in the latter year being 12,646. The year following, the mortality increased enormously, becoming well-nigh doubled—the number of deaths from the malady being 23,711. In 1859, the number fell to 19,310; and in 1860, it became as low as 9,395. Prior to 1855, deaths from scarlatina, cynanche maligna, and diphtheria, were not separated in the Registrar-General's report. Whether the detailed reports of the Registrar-General will show an increase in the mortality in the whole of England from scarlatina, during 1861 and 1862, as great as occurred in London, cannot be predicted. It is certain, however, that the activity of scarlet fever was great in several parts of the kingdom.

The deaths from cynanche maligna in 1855 amounted to 199; in 1858, to 770. In 1860, the mortality from the disease had decreased to 376.

The mortality from measles was largely augmented in 1858; and there was a steady increase in the number of deaths from the disease in the two subsequent years.

The deaths registered from diphtheria in 1855 numbered 186; in 1859, 9,587. In 1860, the mortality from this disease had decreased to 5,212.

The mortality from whooping-cough in 1860 was the lowest since 1852; and the mortality from small-pox had declined from 6460 in 1858 to 2749 in 1860.

The reduced rate of mortality throughout England, which occurred in 1860, was chiefly due, Dr. Farr states, to the decline of the number of deaths from scarlatina, diphtheria, and diarrhoea. A decrease also in the mortality from small-pox, erysipelas, and cholera, contributed to the favourable results.

The most noteworthy fact in the epidemiology of the metropolis during the twelve months, was the remarkable outbreak of typhus. In 1858, 1859, and 1860, typhus had become so rare a disease in London, that the question of converting the Fever Hospital to other uses, was seriously entertained. In 1861, typhus again became epidemic; and since January 1862, the number of admissions to the Fever Hospital for typhus has exceeded that at any period of the history of the hospital. Dr. Murchison attributes this epidemic to the *artificial scarcity* produced by the system of strikes, which had for some time previously disorganised the labour market, and the condensation of population caused by the arrival of labourers in the metropolis from the country in search of work. (See Dr. Murchison's recently published *Treatise on the Continued Fevers of Great Britain*, p. 52, for an account of this epidemic.)

The mortality from continued fever in London, doubtless owing to the outbreak of typhus, was in excess of that of any like period since 1848. Indeed, the total mortality of the winter, spring, and summer quarters of 1862 (2839), from this disease, was alone in excess of that of any year since 1848. The true source of this excess of mortality would not have been rightly understood except by the careful nosological and etiological distinction of the forms of continued fever, insisted upon by Dr. Murchison.

The mortality from scarlatina was but a little below that from continued fever during the twelve months—the total mortality from the former malady being 3437; from the latter, 3463. Next in order of mortality was whooping-cough. Continued fever, scarlatina, and whooping-cough, were the chief epidemic affections of the period under observation in the metropolis. The mortality from continued fever increased to a maximum in the second quarter of 1862. The mortality from scarlatina was at its maximum in the last quarter of 1861, then decreased throughout the two succeeding quarters, but largely increased again in the summer quarter of 1862. The mortality from whooping-cough was greatest in the first quarter of 1862. Diphtheria was still largely fatal, having occasioned 625 deaths.

Mr. Radcliffe detailed the history of the outbreak of

typhus at Preston in Lancashire to the date of reading the report. He dwelt also at some length on epizootic diseases; brought together the chief accessible information on epiphytics; and terminated his report by a brief analysis of the principal contributions to epidemiological literature in Great Britain during 1861-2.

The chief diseases prevalent among domesticated animals were epizootic pleuropneumonia, and the vesicular disease of the mouth and feet. Scores of sheep suffered and were lost from *filaria* in the bronchial tubes and abomasum; there were several local but very fatal outbreaks of influenza among horses; and an outbreak of *variola ovina* occurred in Wiltshire. The history of the latter outbreak, which excited great alarm at the time, will be imperfect until the official reports are published. There was no special disease among plants during the year.

Dr. MURCHISON complimented the author on the valuable report which had been read to the Society; and observed that a continuation of such reports would be of great service to future writers on epidemics. With regard to continued fevers, he pointed out the necessity of distinguishing the different forms, before drawing conclusions as to their causes. The terms "typhus" and "continued fever" were commonly employed to designate different idiopathic fevers arising from totally different causes, as well as many febrile affections symptomatic of local inflammation, which might put on typhoid symptoms. Consequently, all official returns, from which these sources of error were not excluded, were of no value for drawing any inferences as to the probable causes of an increased or diminished prevalence of the diseases in question. He proceeded to allude to certain instances where great misunderstanding had arisen from confounding the different forms of continued fever. Twenty years ago, a memorable discussion took place between the late Dr. Alison of Edinburgh and the London Poor-Law Commissioners, respecting the causes of "fever"—the latter maintaining that it was often due to putrid emanations from decaying organic matter, and was independent of destitution; whereas Dr. Alison asserted that its main cause was destitution, and that putrid emanations had nothing to do with it. Both observers were right; but they referred to different diseases. Dr. Alison's observations were made upon typhus and relapsing fever; those of the London observers on enteric fever. Again, the year 1858, in which the filthy condition of the Thames attracted so much notice, had often been referred to as proving that enteric fever was independent of putrid emanations, because "fever" was less prevalent in London than it had been for many years before. Dr. Murchison did not believe that the condition of the Thames in that year was sufficient to give rise to enteric fever; but he insisted that there was no diminution in the prevalence of enteric fever in London in 1858: the diminished prevalence of "fever" was due to the almost complete disappearance of typhus, which was acknowledged to be independent of putrid emanations. Dr. Murchison then alluded to the present condition of Lancashire, in reference to the appearance of fever. Typhus had broken out at Preston early in October; and from the reports published in the *Times*, as well as from private information, he believed it to be due to overcrowding consequent on destitution. The unparalleled relief which had been afforded to the distressed operatives, and the great ability with which this relief had been distributed, had alone prevented the outbreak of an epidemic, like that which devastated Ireland in 1847, after the failure of the potato crop. It had been repeatedly stated that throughout Lancashire there had not as yet been a single death from starvation. In London, on the other hand, the daily papers reported numerous deaths from starvation; and the poor population had been condensed by the arrival of numerous

labourers from the country in search of employment. Consequently, London had been suffering from the commencement of 1862 from an epidemic of typhus, greater than any which had visited it for many years. Since January 1st, nearly 2,000 cases of true typhus had been admitted into the London Fever Hospital, a far larger number than in any previous year of its existence; and there had also been numerous cases in the other metropolitan hospitals.

Dr. LAWSON, Inspector-General of Army Hospitals, directed attention to the probable existence of a certain epidemic influence, which, for want of a better term, he designated *epidemic force*. His own observations, systematically conducted in several parts of the globe, had shown that, the ordinary local predisposing causes of epidemics being present, epidemic outbreaks recurred with curious regularity. This periodical recurrence indicated, he thought, a law of epidemic action, independent of, although acting concurrently with, the recognised fostering causes of epidemics, which was deserving of wide and attentive examination. The epidemic force, as he characterised the phenomenon, became at times pandemic. He suggested the propriety of keeping this probable epidemic influence in view, in examining the mortality records of this kingdom. They would doubtless throw much light on the subject.

Dr. RICHARDSON remarked that he had been much struck, whilst listening to Mr. Radcliffe's report, with the tacit assumption by the author of the spontaneous development of certain epidemic contagious affections. He thought that the question of the spontaneous development of contagious maladies of an epidemic character was open to much doubt. He believed that it was a question which might with much advantage be submitted to discussion by the Society. He would, therefore, with the permission of the members, take an early opportunity of asking the Society to express an opinion upon the debated points.

#### LIVERPOOL MEDICAL INSTITUTION.

JANUARY 8, 1863.

A. B. STEELE, Esq., Vice-President, in the Chair.

*Imperforate Anus.* The CHAIRMAN mentioned that the case of imperforate rectum reported at the last meeting had terminated fatally. Obstruction had come on, followed by swelling of the belly and sinking. He was not allowed to make a *post mortem* examination.

*Tumour containing Hair.* Mr. LOWNDES shewed a tumour of about the size of a filbert, which was removed from the upper part of the outer angle of the orbit, and contained loose hairs in it, and had hair growing on its lining membrane.

*Cystic Disease of Breast.* Mr. FLETCHER shewed a specimen of cystic disease of the breast, removed from a woman aged 35. It had existed for a year. It was found to be a complete cystic tumour with a large fungus protruding into one cyst.

*Wound of the Penis.* Dr. NOTTINGHAM brought forward a case of extraordinary wound of the penis. He said it was more properly a wound of the penis received in an extraordinary way. A gentleman, after intercourse with his wife, observed hæmorrhage, and an incised wound of the penis. It appeared that his wife had been using a glass syringe some days before. On examination, Dr. Nottingham found a piece of glass behind the uterus fixed at one point. He made use of a four-barred speculum to open out the vagina, and removed the piece of glass with forceps. It suggested itself to him that, in such a case, the fragment might be pushed through the peritoneum. The woman was unconscious of its presence. He shewed the fragment, which was very thin and sharp; and also the syringe from which

it had become detached. In another case, he had found several pieces of glass in the vagina. These glass perforated syringes are very thin and dangerous, and he always recommended a Higginson's syringe and porcelain tube.

Mr. DENTON had met with a case in which, during intercourse, the husband met with an alarming accident. A stem pessary which the female was wearing had become inverted, and the stem, projecting into the vagina, had entered the man's urethra and caused great pain and great hæmorrhage.

Mr. HIGGINSON said that some pessaries, when the stems are short, are liable to turn round, and also to drop out entirely. He might be allowed to say that he had no doubt in the world of the value of a stem in cases of anteversion, retroversion, and dysmenorrhœa.

*The Turkish Fever Ship.* Mr. HIGGINSON read a paper on information collected at Malta and Alexandria respecting the crew of a Turkish frigate, on their voyage from Egypt and return thither, in reference to the outbreak of fever in Liverpool in 1861. Mr. Higginson observed that the medical history of that outbreak of fever is contained in thirteen papers in the *Medical Times and Gazette*, April to July 1861; in four papers in the *Lancet*, April 1861; and in a paper by Dr. Duncan in the first volume of the *Transactions of the Epidemiological Society*, 1862. Thirty-two sick men from the *Schah Gehaad* were admitted into the Liverpool Southern Hospital, four of whom died of dysentery; "there was no typhus." Nevertheless, typhus attacked those who attended on the Egyptians on board the ship, at the baths, and in the hospital; thirty-one people were seized with typhus, and eight died. Mr. Higginson learnt at Malta that when the *Schah Gehaad* arrived there from Alexandria on her way to England, seventy-three of her crew were received into hospital; namely, seventeen cases of febris intermittens, thirty-seven of febris continua, eight of gastritis, four of diarrhœa, and seven of other diseases. One case only of those of febris continua proved fatal; and he was told that the cases classed under this head presented "a pulse of about 100, skin hot, no eruption, tongue white and coated, but not dry; they always had an appetite." Into the same hospital, there were received from the *Voyageur de la Mer*, on her way from England to Egypt, nine cases, of which two were classed under the head of febris continua, and of these one died. There were one case of gastritis, four of diarrhœa, and two of rheumatism. The captain also died of fever, and a resident engineer, who worked on board one night, also took fever (true typhus), and died about the ninth day. At Alexandria, Mr. Higginson learnt that about twenty-five of the Arab crew had been taken to hospital, fourteen of whom had symptoms of continued fever, and of these one died, which was the only death of those arriving in Egypt. Six European passengers, who suffered from a febrile attack more or less severe, all recovered. No contagion is known or suspected to have emanated from these cases. From these data, Mr. Higginson inferred that, in the case of these Egyptians, the same poison may produce fever in hot and dysentery in cold climates.

Dr. CAMERON said that in Mr. Higginson's account it seemed that out of seventy-three cases in the first series, only one proved fatal. These could not then be cases of true typhus, but might be of febricula. This form of fever is recognised and described by Dr. Murchison. With regard to the cases that were under his own care at the Southern Hospital, much had been said and written about them, and he had re-considered them most carefully, and the only conclusion he could come to was that they were certainly not cases of true fever. There was a total absence of prostration; the patients were generally able to walk, and they could eat well; there was no delirium; the tongue was clean. Again, more than 200 men worked on board the ship, and did not

take fever. This was not like the contagiousness of ship fever. He referred to several authorities on this point.

Mr. IRVINE, referring to his own published statement on this subject, said that the cases he had there classed under the head of constipation might, perhaps, like Dr. Cameron's, have been cases of febricula. During their stay these patients shewed no signs of true fever, and they bore with impunity the rough treatment they were subjected to on board ship.

Mr. FLETCHER thought Mr. Higginson's paper valuable as proving that there was nothing like typhus at Malta, whatever the physician there chose to call the slight cases under his care. The dirt and emanations from these Turks at the hospital were quite sufficient to give rise to fever. At the Paul Street Baths men took fever after being only a very short time in contact with these patients.

Dr. NOTTINGHAM said that these Egyptians had been closely packed, and exposed to all the circumstances calculated to cause an outbreak of fever; had they been Saxons they ought to have had fever, at any rate when they got into the typhus regions. He is disposed to believe that that Oriental race is less liable to typhus than we are.

Dr. CAMERON said it was very remarkable that those patients of his, whatever disease they themselves had, imparted true typhus to the Europeans who were exposed to the infection.

Dr. Vose, during the outbreak in question, had attended a clergyman who had contracted the disease at the Southern Hospital. He had distinctly typhus—measly eruption, etc. These filthy Egyptians seemed able to radiate a disease distinct from their own.

## WESTERN MEDICAL AND SURGICAL SOCIETY.

FRIDAY, JAN. 16TH, 1863.

M. BAINES, M.D., Vice-President, in the Chair.

ON SOME POINTS IN CONNECTION WITH CEREBRAL HÆMORRHAGE. BY T. JONES, ESQ.

The author's opinions were based upon forty fatal cases which had occurred at St. George's Hospital. These were taken indiscriminately; but after a careful scrutiny, selecting only those cases in which a perfect *post mortem* examination of all the organs of the body took place, and in which a visible hæmorrhage could be demonstrated from the cerebral arteries, thirty-six cases were found perfectly reliable for his remarks. Of the predisposing causes, the influence of age was first discussed; and, contrary to what had been often advanced, he shewed that the greater number of cases occurred between the ages of 40 and 50; for in thirty-eight cases, he had found three had occurred between 30 and 40 years; thirteen between 40 and 50; ten between 50 and 60, nine between 60 and 70; and three between 70 and 80. But a further examination showed that by comparing the numbers of cases with the respective numbers of population at similar ages, the period of life at which the disease was most prone to occur relatively was between 60 and 70; for between 30 and 40 years, three cases occurred in a population of 2500; between 40 and 50, thirteen cases in a population of 1800; between 50 and 60, ten cases in 1300; between 60 and 70, nine cases in 1000; and between 70 and 80, three cases in a population of 500.

With regard to sex, males were shown to be more liable to the disease than females; for of forty cases, 11 only were females.

Mr. JONES next described the efficient causes of cerebral hæmorrhage, and the intimate connexion between the latter and disease of the kidneys, heart, and arteries. This being one of the principal objects of the paper, he entered minutely into details of the thirty-six fatal cases,

in which disease of the kidneys, or the heart, or arteries, was found, conjointly or singly, with cerebral hæmorrhage. The analysis of these thirty-six cases was then examined; the result being that disease of the cerebral and other vessels, of the heart, of the kidneys, was found in conjunction ten times; disease of the cerebral vessels, of the heart, of the kidneys, twenty-two times; disease of the heart and kidneys, twenty-nine times; of the cerebral vessels and kidneys, twenty-two times; of the cerebral vessels and heart, twenty-four times; of the cerebral vessels and heart (hypertrophy), ten times; of vessels not cerebral and kidneys, thirteen times; of vessels not cerebral and heart, thirteen times.

The further results of the analysis showed that in more than one-half the cases, the kidneys, heart, and cerebral vessels were simultaneously affected, and in almost all those cases in which there was absence of disease in one or other of these organs, there was the history of an accident to which the attack was attributed.

The various morbid appearances found in the kidneys, heart, and arteries, under the foregoing circumstances, were fully and minutely explained, the author being strongly of opinion that the diseased condition of the kidneys first led to that of the arteries, and subsequently to the heart.

In support of this opinion, Mr. Jones offered an hypothesis to the effect that the kidneys, from their disorganised state, being unable to depurate the blood on the one hand, but allowing the albumen to unduly pass away on the other, this fluid was rendered unfit to carry on the nutrition of the tissues, and that the arteries suffered early from this defective nutrition. The conclusions which the author drew from his examination of the subject, were:—

1. Cerebral hæmorrhage, when associated with renal disease, is almost always found to be dependant upon rupture of one or more of the cerebral arteries, in consequence of certain morbid changes having taken place in their walls.

2. These changes in the walls of the vessels are induced by the altered state of the blood, the effect of advanced disease of the kidneys.

3. The enlargement of the heart is the immediate effect of the renal disease, conjointly, perhaps, with the alterations in the coats of the vessels.

The paper concluded with some remarks upon the treatment of these cases, in which a tonic and stimulating plan, rather than a lowering one, was advocated, and two cases were given, which seemed to justify it.

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JANUARY 27TH, 1863.

SAMUEL SOLLY, Esq., F.R.S., in the Chair.

CASE OF WHITE FIBRO-SEROUS DISCHARGE FROM THE THIGH. BY A. B. BUCHANAN, M.D., GLASGOW.

[Communicated by E. H. STEVEKING, M.D.]

THE author recorded the history of a remarkable case of discharge of white fibro-serous fluid from the posterior cutaneous surface of the thigh, under his care in Glasgow. The patient was a woman, in other respects in fair health, aged 46, and mother of six healthy children. The discharge was white, like milk, and flowed from excoriations produced by the rupture of small vesicles scattered over the back of the thigh; and particularly from an infiltrated patch, of the size of the palm of the hand, on which the vesicles and excoriations were most abundant. The milky fluid coagulated a few minutes after being passed. It contained a fatty molecular base, similar to that of chyle, and a few nucleated cells. The results of a chemical analysis closely corresponded with those yielded by "chylous urine."

The patient dated the commencement of her malady from a shivering fit twenty-one years ago, shortly after which she noticed a "lump" in the situation of the affected surface. Fifteen years ago vesicles appeared, from which a brownish fluid exuded on scratching. For the last six years the discharge had been milk-white, and was always worst in wet weather, and while the patient was walking about, when its amount might be half a pint per hour. At night it ceased to run, recommencing about an hour after the patient rose in the morning; but in dry and frosty weather it was occasionally absent for a week or two. The veins of the affected limb were varicose, but no enlargement of the lymphatic glands could be detected. The author succeeded in controlling the discharge for two months by a long elastic stocking; the use of which, however, had to be discontinued, owing to severe lancinating pains in the thigh. The breasts also swelled, and began to secrete small quantities of colostrum. Immediately on ceasing to use the stocking the uneasy sensations subsided, and the discharge commenced anew.

After remarking that cases of this affection were extremely rare in temperate latitudes, Dr. BUCHANAN pointed out, by referring to several recent examples, that they were probably more frequent in warm climates. He cited, however, and gave an account of, two unequivocal cases of the same affection, both dating from the seventeenth century; one of which, in a male subject, occurred in Germany, and the other, in a female, in France.

While referring to various pathological theories, the author fully recognised the identity of the above disease with "chylous urine," or, as he would prefer to call it, "white fibro-serous urine." He objected particularly to the theory which identified white fibro-serous discharges in general with chyle. He gave his reasons for believing that it was more natural to consider them as equivalent to the white liquor sanguinis—to transudations of the serum of the blood during its periodical milkiness after meals, but with certain modifications inseparable from the mode of its secretion. Thus, while the water, albumen, and salts, and possibly also the fibrine, would come from the blood directly, he showed that the cells present in the discharge must be derived from the secretory layer of the skin, or from the epithelium of cutaneous glands. He contended that the molecular base was unquestionably derived from the blood; but that the molecules could not be conceived to filter directly through the walls of the vessels without presupposing the existence of a uniformly and intensely milky serum while the discharge was flowing, even at long intervals after meals. To avoid this difficulty, it might be supposed that the epithelial cells of the glands of the skin had the power of separating, by a perverted function, fatty matter from the blood, much as the epithelial cells of the intestine are concerned in filtering it into the lacteals. The cells would then become gorged with fatty molecules, and the uniformly white colour of the discharge would be accounted for without its being necessary to suppose that the liquor sanguinis was ever milky except, as usual, after meals. On this view, white fibro-serous discharges would depend immediately on deranged glandular action, and the foregoing case might be defined as a rare functional affection of the glandular apparatus of the skin.

The paper was illustrated by specimens of the milky discharge and by a drawing of the diseased surface.

REPORT ON SYPHILIS AS A CONSTITUTIONAL DISEASE. BY J. MARSTON, M.D.

A portion only of the report was read, and its further reading was adjourned to Feb. 10th.

#### NEW LITHOTRITES.

Mr. HENRY THOMPSON exhibited some lithotrites of a new construction, on behalf of Messrs. Weiss and Son,

who wished to show them to the fellows of the Society before making them generally public. As the alteration appeared to him a real improvement, he readily assented to do so. He premised that this related entirely to the mode of applying and disengaging the power, and not at all to the part concerned in crushing the stone. In order to demonstrate the qualities of these instruments, it was necessary to call to mind what are the main points to be achieved in constructing the movement of a first-rate lithotrite. 1. Economy of time in its action; anything which shortened the period necessary to a proper performance of the operation in the bladder was so much clear gain to the patient. 2. To reduce to a minimum vibration or concussion in its action. 3. To permit the utmost delicacy of perception, especially valuable in dealing with small fragments. He showed the deficiency of the old screw instrument in all these respects, and the inferiority of this latter to the instrument known as Charrière's, which was now so commonly substituted for it. He showed the improvement made by Mr. Coxeter, and placed in the International Exhibition; and finally demonstrated the action of Weiss's new instrument as uniting all the characters given above with the greatest strength, comparing it also with the rack and pinion instrument, to the advantage of the former. The power in Weiss's instrument is that of the screw; it is disengaged and converted into sliding action with the most perfect ease, and without moving the hand, while the entire instrument can be changed in direction, or even entirely rotated, by a light application of the finger and thumb. The apparatus for accomplishing this is exceedingly simple, at the same time very strong, and not liable to get out of order.

## Correspondence.

### PREFERMENT BY AFFECTION.

SIR,—I venture to address you on a subject which is at present engrossing the attention of the medical profession in this town, and which, I have reason to believe, is not indifferent to the general public.

You are no doubt aware that there are in Lancashire, numerous medical appointments, in connection with the staple manufacture—cotton, of considerable value; these being held for life, as under the Poor-law, or during the *good behaviour*, as it is called, of the incumbent.

They are government offices, and in the gift of the Inspector of Factories for the district in which a vacancy occurs. Those who hold them are denominated, "certifying surgeons to the factories," because all children under the age of 16 have to undergo medical inspection before they can be employed as factory operatives. The *direct* pecuniary value of these appointments varies from £100 to £400 *per annum*; and *indirectly*, they are a means of introduction to much surgical practice, considerably more. In the town of Oldham, there are two such appointments; one, the largest in the country I am told, is supposed to yield between £400 and £500 *per annum*; the other from £250 to £300. It is with the latter I have to do.

You may naturally suppose, that whenever a vacancy occurs, there is much emulation amongst the medical residents to gain the prize, especially as the duties pertaining to the position are by no means onerous, and perfectly compatible with the conduct of a large general practice.

It has been customary for the Inspector when called upon to discharge this public trust, to nominate some medical gentleman of established reputation, resident in the town, and possessing the confidence of the public.

During the past week, the death of Mr. Earnshaw, one of the certifying surgeons here, has placed at the

disposal of the Inspector of the district the appointment of a successor. Judge of the surprise of the profession when it was announced that, ignoring age, reputation, and status, he had violated his trust by nominating a non-resident young gentleman, who has just completed his education, the son of a sub-inspector in a neighbouring district! Is it a matter of surprise that all here view this proceeding as a deliberate insult, and a gross piece of official jobbery? We are anxious to take such steps as may manifest this opinion, having in view either the annulling of this appointment, or the prevention in future, here and elsewhere, of a similar injustice. It has been determined, therefore, to call a meeting of the profession in the course of a few days; and it would much aid their object to be fortified by the support of the medical press. It is to the interest of all of us that nepotism should be strangled in its birth.

I am, etc., BETA.

Oldham, January 27th, 1863.

### DYSCHROMATODERMA.

LETTER FROM C. HANDFIELD JONES, M.B., F.R.S.

SIR,—Will you allow me, through the medium of the JOURNAL, to call Mr. E. Wilson's attention to an interesting instance of dyschromatoderma, which he has not alluded to in his recently published essay? I refer to the peculiar dark suborbital tinging of the skin which accompanies aguish disorder, and which is perhaps oftenest observed in children. It forms a curve, commencing and being deepest near the inner canthus of the eye, and gradually shading off into the usual tint of the face as it passes below the inner and lower part of the orbit. The parents notice it readily, and say their child is "so dark under the eyes". It does not appear to be a permanent discoloration, as it disappears when health is regained. It is a really valuable sign of the presence of aguish affection, and as such I have long been acquainted with it. Till lately, however, I have been rather inclined to ascribe it to some venous congestion; but I am now more disposed to adopt the view that it depends on pigmentary deposit, derived from abnormal changes taking place in the blood. It is very probable that other causes besides malarious disease may induce it, but I have not observed it so marked in any other states as in this.

I am, etc., C. HANDFIELD JONES.

London, January 1863.

### THE TITLE OF DOCTOR.

SIR,—I have found the opinions editorially enunciated by you in our JOURNAL generally so just, that it is with diffidence I venture to differ from you as to permitting the claim set up by some of the Licentiates of the Edinburgh College of Physicians to the title of "Doctor". No doubt Licentiates practising as physicians only have been customarily addressed as Doctors, as no other title could properly designate them; but the case is widely different when my unscrupulous opponent—the general practitioner—invests £10 in a license, with the purpose of imposing upon the public by falsely representing himself as having a title which gives him a superior professional status to myself. We have in our town two of these Edinburgh Licentiates, and one of them (who signs himself Dr. —, Physician, Surgeons, etc.) industriously circulates the report that he has a higher professional title than myself; and I am convinced that, if we silently allow this assumption, the public will be cheated into this belief; indeed, I have daily knowledge that such is the fact. Then why should I lend myself, contrary to my conscience, to aid in disseminating a falsehood by calling a general practitioner "Doctor", when he has no degree, and his only

title to it is "humbug"? Of what is he Doctor? Certainly not of medicine; and I do not understand how any honourable Licentiate can expect as a right to be called Doctor, when his College cannot and does not pretend to give him the title. I shall, therefore, as a duty to myself, oppose such an assumption, and decline to address a mere Licentiate as "Doctor", even at the risk of "exposing myself to the charge of discourtesy and to angry rebuke". I hope that our Association will take up this matter, and follow the example of the Manchester Medico-Ethical Society, which some time ago resolved that a Licentiate was not entitled to be called Doctor, as I am convinced that the more respectable members of our profession will not from any feeling of courtesy give the title of Doctor to those who, from the desire to rise higher than their competitors, resort to such an imposition.

I am, etc., F.R.C.S.

February 3rd, 1863.

[Our correspondent must recollect that, if there is any blame to be attached to any one in this matter, it is to the authorities of Colleges of Physicians, who during that famous year of grace (or money-making) deluged the country with ready-made physicians. No one before that day refused the courtesy title of "Dr." to a physician; and we must confess (and for reasons which we have already given at length) that we do not see how the title can be refused now. There are, we believe, still alive gentlemen, non-diplomatised, to whom the London College many years ago actually gave distinct permission to take the title of Doctor. How would our correspondent deal with them? The tacit gift of the "Doctor" was part of their bargain with the College. But if we give the title to one physician, how can we refuse it to any physician? But there is another important view of the question, to which we would seriously invite attention. Do these titles really give a man any special advantage in the eyes of the public? Is not a man's honourable position won by his own honourable conduct, whatever be his medical testimonial—whether diploma or license? We have given long and earnest consideration to the subject, and we can come to no other conclusion than that we have done. EDITOR.]

### PUBLIC GRATUITOUS MEDICAL SERVICE.

SIR,—Mr. Spencer Wells deserves the thanks of the profession for exposing the injustice attempted to be inflicted on us by the Liverpool and London Assurance Office. As this is, perhaps, the only species of the numerous demands on our gratuitous service that has been successfully resisted, it occurs to me to ask whether the other Protean exactions on the time and skill of the profession cannot be withstood on the same grounds?

Foremost, and may be parent of all, there is the monstrous injustice of gratuitous service at our hospitals and dispensaries, where the general public require us, at the cost of much time, skill, and labour, to treat the ailments of their nominees, dependants, or labourers, as the case may be. Now, the public (*i.e.*, the subscribers to these institutions) obtains a large amount of valuable service, if not actual profit, from the labour rendered or preserved to it by us at these institutions. Ought we not, therefore, to participate in this profit as a reward for our services? "Woe unto him," exclaimed the prophet of old, "that buildeth his house by unrighteousness and his chambers by wrong; that useth his neighbour's service without wages, and giveth him not for his work." (Jeremiah, chap. xxii, 13.) Now, that cottage hospitals and dispensaries are being opened every day, it is high time that some steps, such as those suggested by Dr. Gibbon, should be taken by our Association to scotch if not to cure the evil.

I am, etc., M.D.

## Medical News.

**APOTHECARIES' HALL.** On January 22nd, the following Licentiate was admitted:—

Nesham, Thomas Cargill, Newcastle

**Admitted on January 29th:—**

Brittain, Thomas Lewis, Chester  
Ellis, Heber Dowling, St. Bartholomew's Hospital  
Gray, Frederick John, March, Isle of Ely  
Handley, Joseph, King Street, Oldham  
Johnson, James Mercer, Everton, Liverpool  
Lyman, John, Weston Favell, Northamptonshire  
Mann, John Dixon, West View, Kendal  
Matthews, James, Cowes, Isle of Wight  
Miller, John Nicholas, The Square, Hampstead  
Patrick, Samuel Alexander, Tipping Street, Manchester

### APPOINTMENTS.

Fox, Wilson, M.D., appointed Assistant Physician to University College Hospital.

\*HARLEY, George, M.D., appointed Assistant Physician to University College Hospital.

MATTHEWS, Charles S., Esq., elected Surgeon to the Farringdon General Dispensary.

MURRAY, J. Jardine, Esq., appointed Surgeon to the Brighton and Sussex Infirmary for Diseases of the Eye.

WILLIAMS, William R., L.R.C.P.Ed., appointed Resident Apothecary to Bethlehem Hospital.

### POOR-LAW MEDICAL SERVICE.

GRAHAM, Fitzgibbon L., L.K.Q.C.P.L., to be Medical Officer to the Celbridge District of the Celbridge Union, co. Kildare.

HORTON, Henry, Esq., to be Medical Officer for the West District of the parish of Wednesbury.

RUSSELL, William S., Esq., to be Medical Officer for the Eckington District of the Chesterfield Union.

SHANNON, Thomas E., M.D., to be Medical Officer for the Ropsley District of the Grantham Union.

### ARMY.

LAMP, Staff-Assistant-Surgeon H., to be Assistant-Surgeon 50th Foot, *vice* O. Owen.

To be Staff-Assistant-Surgeon:—

OWEN, Assistant-Surgeon O., 50th Foot.

### ROYAL NAVY.

CALDWELL, John, Esq.	} Assistant-Surgeons to be Surgeons.
COULMAN, Thomas, M.D.	
CONICE, William H., Esq.	
EVANS, Richard, Esq.	
CRAWFORD, William, Esq., Surgeon (supernumerary), to the <i>Clyde</i> convict-ship.	
FERGUSON, Robert, Esq., Assistant-Surgeon, to <i>Itaslar</i> Hospital.	
FLETCHER, William B., Esq., Acting Assistant-Surgeon, to the <i>Narcissus</i> .	
LITTLE, Archibald J., Esq., Staff-Surgeon, to the <i>Colossus</i> .	
POWELL, W. L., Esq., Assistant-Surgeon, to the <i>Racoon</i> .	
STABLES, William, Esq., Acting Assistant-Surgeon (additional), to the <i>Narcissus</i> .	
YOUNG, James, M.D., Surgeon, to the <i>Racoon</i> .	

### INDIAN ARMY.

JOHNSON, Assistant-Surgeon C., Bengal Army, to be Surgeon.  
PEARSON, Assistant-Surgeon F., Bengal Army, to be Surgeon.

**VOLUNTEERS.** (A.V.—Artillery Volunteers; R.V.—Rifle Volunteers):—

GOULD, W., Esq., to be Assistant-Surgeon 2nd Manchester R.V.

To be Honorary Assistant-Surgeon:—

MARSHALL, W., M.D., 1st Dumfriesshire R.V.

### BIRTH.

HEWITT. On February 1st, at Winkfield, near Windsor, the wife of \*T. S. Hewitt, M.D., prematurely of a son, who survived but a few hours.

### DEATHS.

BEALE, Miles, Esq., Surgeon, at 31, Finsbury Square, on Feb. 2.  
BUCKNILL, Samuel, Esq., Surgeon, at Rugby, aged 78, on Feb. 1.  
CUMMING. On January 30th, at Limehouse, aged 26, Duncan, youngest son of W. S. Cumming, Esq., Surgeon.  
EARNSHAW, John, Esq., Surgeon, at Oldham, on January 17.  
HALLAM, William, M.D., at Newcastle, Staffordshire, aged 49, on January 30.  
HARRIOTT, Wm., Esq., Surgeon, at Rainford, aged 38, on Jan. 30.

HOVELL. On January 30th, at Clapton, aged 3, Henry S. R., third son of D. De Berat Hovell, Esq., Surgeon.  
HUDSON. On January 29, at Shepton Mallet, Jane, wife of Thomas St. J. Hudson, Esq., Surgeon.  
JOHNSTONE. On December 24th, 1862, at Rajecto, Elizabeth, wife of Assistant-Surgeon T. P. Johnstone, 16th Native Infantry.  
SHERWOOD. On January 20th, at Melcombe Place, Dorset Square, aged 5 years, Digby, youngest son of W. H. Sherwood, M.D., of Bathurst, Gambia.

**THE CONSOLIDATED FUND.** The Lunacy Commissioners', etc., expenses were £11,929 in 1861-2, as compared with £12,278 in 1860-1.

**ROYAL COLLEGE OF SURGEONS.** The Hunterian oration will be delivered on Saturday next, in the theatre of the College, at three o'clock, by Professor Gulliver, F.R.S., and on Tuesday Professor Huxley, F.R.S., will commence his course of lectures.

**THE QUEEN'S PHYSICIAN.** On the occasion of the christening of the infant son of Dr. W. Jenner on Friday week, her Most Gracious Majesty was pleased to stand sponsor, being represented on the occasion by Lady Augusta Bruce, who, in obedience to the wishes of the Queen, gave the boy the name of Alfred Victor, accompanied with the present of a magnificent tankard, bearing a suitable inscription, and as a Royal recognition of the great professional attention paid by Dr. Jenner to his Royal Highness the Prince Consort.

**SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN IN LONDON AND ITS VICINITY.** A half-yearly general meeting of the members of this society was held on January 28th, T. A. Stone, Esq., President, in the chair. It appeared that during the past year £1,933 had been distributed in half-yearly grants amongst forty-three widows and twenty-six orphans of former members; £10: 10: in immediate relief to a family; £45 towards the self-maintenance of two older orphans; £15 for extra relief to a widow; and £20 as a special grant to an adult son in great distress and illness abroad. We are happy to state that a much larger number than usual of new members has been elected by the Society, and we hope that this increased ratio will continue, so lamentable, and often unexpectedly, is the condition of the families of deceased medical men. The following officers and directors for the ensuing year were elected: *President*—T. A. Stone, Esq. *Vice-Presidents*—M. Ware, Esq.; E. A. Brande, Esq.; P. M. Latham, M.D.; J. Bacot, Esq.; T. Turner, M.D.; D. H. Walne, Esq.; A. J. Sutherland, M.D., F.R.S.; E. Tegart, Esq.; G. Burrows, M.D., F.R.S.; John Miles, Esq.; Sir John W. Fisher; Caesar H. Hawkins, Esq., F.R.S. *Treasurers*—J. T. Ware, Esq.; G. H. Roe, M.D., (Atg.); R. S. Eyles, Esq. *Directors*—B. G. Babington, M.D.; J. Wetherfield, Esq.; J. J. Sawyer, Esq.; T. Brown, Esq.; C. J. B. Aldis, M.D.; W. Dickinson, Esq.; J. C. Salisbury, Esq.; H. Blenkarne, Esq.; T. K. Chambers, M.D.; J. Clarke, M.D.; D. Scannell, Esq.; P. E. Hewett, Esq.; W. J. Little, M.D.; J. G. Forbes, Esq.; W. Munk, M.D.; B. W. Holt, Esq.; C. Miles, Esq.; W. Cathrow, Esq.; H. Sterry, Esq.; A. Fisher, Esq.; H. Jeafferson, M.D.; J. Paget, Esq., F.R.S.; H. S. Illingworth, Esq.; F. Hawkins, M.D. The seventy-fifth anniversary dinner of the Society, is appointed to take place on May 20th, at the Albion Tavern.

**ABUSE OF TOBACCO.** There is another habit respecting which I shall venture to say a few words, because it is both a bad one and a comparatively new one—I mean the immoderate use of tobacco—a habit brought amongst us from the continent of Europe, on the cessation of the French revolutionary war. Young military men are apt to regard the habit as a manly one, until severe dyspepsia, giddiness, shattered nerves, sallow complexion, disturbed action of the heart, and other symptoms show themselves, and then it is frequently too late to stop. "The sallow complexions, black, broken, and unsound teeth"

of the Germans are matters of notoriety to all travellers. "You may," says one of them, "smell a German in any part of the room, or scent him at a quarter of a mile's distance in the open air, if the wind be favourable. Much is talked of the good effects of tobacco-smoking in damp and malarious localities, by persons who, in defiance of geographical differences, carry the habit wherever they go—from the marshes of Burmah to the arid plains of Hindustan, forgetting that, meanwhile, in the language of Cassio, "they put an enemy in their mouths to steal away their brains;" but I think there is good reason to question the benefits of this habit of smoking even in the fatherland of fog and damp, or that tobacco ever acts as a preventive to any disease, and least of all to fever. The truth is, that many persons puff themselves into the good graces of snops and spoonies like themselves, and use cigars by the score now, as Lord Chesterfield drank and smoked in his time, notwithstanding his aversion to wine and tobacco—"because he thought such practices very genteel, and made him look like a man." How his lordship may have looked under the united influence of wine and tobacco, his biographers have failed to relate; but we all know how our modern "spoonies" and "snobs" in our thoroughfares look after a course of cigar-smoking alone. (*Sir R. Martin.*)

#### OPERATION DAYS AT THE HOSPITALS.

MONDAY.....Royal Free, 2 P.M.—Metropolitan Free, 2 P.M.—St. Mark's for Fistula and other Diseases of the Rectum, 1.15 P.M.—Samaritan, 2.30 P.M.—Lock, Clinical Demonstration and Operations, 1 P.M.

TUESDAY. .... Guy's, 1½ P.M.—Westminster, 2 P.M.

WEDNESDAY... St. Mary's, 1 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.

THURSDAY..... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—London, 1.30 P.M.—Great Northern, 2 P.M.—London Surgical Home, 2 P.M.—Royal Orthopaedic, 2 P.M.

FRIDAY. .... Westminster Ophthalmic, 1.30 P.M.

SATURDAY..... St. Thomas's, 1 P.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.

#### MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY. Medical Society of London, 8.30 P.M. Mr. Thomas Bryant, Lettsomian Lecture "On the Differences between the Physiological and Pathological Processes in Children and Adults, and on some Congenital Deformities, as Harelip and Malformations of the Rectum."—Royal Geographical.

TUESDAY. Royal Medical and Chirurgical Society, 8 P.M., Ballot; 8.30 P.M., Continuation of Dr. Marston's paper on "Constitutional Syphilis"; Mr. T. Longmore, "On Two Cases of Kelts."—Zoological.

WEDNESDAY. Society of Arts.—Microscopical.—North London.

THURSDAY. Royal.—Antiquarian.

FRIDAY. Astronomical.—Royal Institution.

SATURDAY. Royal Botanical.

#### POPULATION STATISTICS AND METEOROLOGY OF LONDON—JANUARY 31, 1863.

[From the Registrar-General's Report.]

	Births.	Deaths.

#### TO CORRESPONDENTS.

\*. All letters and communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen St., Lincoln's Inn Fields, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

DR. HARRISON'S BOOK ON CHILDREN.—SIR: I beg respectfully to state, that the comments made on my little work on the *Diseases of Children*, in the BRITISH MEDICAL JOURNAL of December 13th, 1862, appear to me unfair in imputing to me a wish to "cast reflections on the medical body in general." I must distinctly deny the most remote intention of so doing. On the contrary, I have always entertained a high opinion of the medical profession as a body, both for its enlightened humanity and varied learning. At the same time, I cannot but think that remarks which are not of a personal nature, may be fairly directed against errors which occasionally arise. Indeed, you properly say yourself in the next issue of your JOURNAL, page 600: "We need not tell our correspondent that from one end of the country to the other amateur and professional quacks daily prescribe and daily administer medicines."

I am, etc.,

J. BOWER HARRISON.

Higher Broughton, Manchester, January 1863,  
[We willingly insert Dr. Harrison's note. We are satisfied, however, that the construction we put upon Dr. Harrison's words, as they stand in his book, was the legitimate one. We are very glad to hear from him that no such idea was present in his mind in writing them. EDITOR.]

FOREIGN PRACTICE BY ENGLISHMEN.—SIR: Can you inform me what examination an English registered M.R.C.S. is required to pass, before he is allowed to practise in a French town?

I am, etc., H. W.

[We believe that there is something more than examination required. It is requisite for a foreigner to obtain permission from *l'autorité* to settle in France as a medical man; and we have always understood that such permission is not easily obtained. EDITOR.]

DECAPITATION BY HANGING.—Dr. Gibb has kindly sent us a Canadian newspaper, containing an account of the decapitation already referred to in this JOURNAL. We must still, notwithstanding the printed details, hold the fact as hard of belief. If the body was emaciated, its weight would have been slight. *No medical man gives any information on the subject.* It seems incredible that any rope of the ordinary strength used in hanging criminals, should not give way, rather than the neck. We read in the journal referred to:—

"The fall being so great, and the man's body being in a diseased condition, the vertebrae and muscles connecting the head with the shoulders gave way, and, terrible to relate, the head rolled off, while the body fell with a heavy plunge into the interior of the scaffold! The life-blood of the criminal poured out in livid streams from the headless trunk, while the torn muscles and gaping arteries presented a sickening spectacle."

W. C.—Our correspondent is, no doubt, aware that it is often much easier to ask than to answer a question. The names attached to the programme prove the authenticity of the society; but, with regard to the announced proposal of a new society, we are disposed to think that, as so many societies now exist in this metropolis, to invent a new one, except upon very distinct and urgent grounds, is very undesirable. An Anthropological Society certainly seems to us to be, from its title, much of a kin with the Ethnological Society; and, if it really be so, then we can only say that, in our opinion, it falls under the category of an undesirable novelty. To the institution as a publishing society, however, there may be less objection.

COMMUNICATIONS have been received from:—Dr. WILLIAM RUDD; Mr. H. HAILEY; THE HONORARY SECRETARY OF THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY; Dr. J. HUGHES BENNETT; Mr. P. HEWITT; Mr. THOMPSON; Dr. HANDFIELD JONES; Mr. ROGERS; Dr. COLE; Dr. SKINNER; Mr. LIONEL BEALE; Mr. A. B. STEELE; Mr. J. KENT SPENDER; Mr. HENRY WADE; Dr. HEWITT; Dr. TENISON; Mr. S. BENDROFT; Mr. KENT JONES; Mr. W. COOKE; Mr. J. B. CURGENVES; H. W.; Dr. JAMES RUSSELL; Dr. STRAP; Mr. S. WOOD; Mr. T. M. STONE; THE REGISTRAR OF THE MEDICAL SOCIETY OF LONDON; Mr. DUNN; Mr. P. LESLIE; and Mr. J. J. GODFREY.

# Facts and Arguments

OPPOSED TO

## DR. BENNETT'S THEORY OF ORGANISATION.

BY

LIONEL S. BEALE, M.B., F.R.S.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS; PROFESSOR OF PHYSIOLOGY AND OF GENERAL AND MORBID ANATOMY IN KING'S COLLEGE, LONDON; PHYSICIAN TO KING'S COLLEGE HOSPITAL; HONORARY FELLOW OF KING'S COLLEGE; ETC.

DR. BENNETT deprecates further discussion until the whole of his lectures are published; but as this theory is not a new one put forward for the first time by a young observer, as most of the statements have been repeatedly made, as the same facts and arguments have been advanced before, and many of the drawings now being published have been already used for illustrating similar observations, there seems to me no sufficient reason for postponing the discussion already commenced; and if the forthcoming lectures contain as many statements open to discussion as those which have already appeared, the task of criticism would be too great to attempt. Nor would it be just to the author to raise objections so long after the statements which called them forth had appeared.

Moreover, when a public teacher of deservedly high repute, and an examiner in one of our great universities, makes such vague statements as the following, "*the molecules of the ovary first coalesce to form the ovum*"—"after fecundation the *spermatozooids and germinal vesicle disintegrate and form histolytic molecules*,"—it seems only right to ask at once for further explanation, for it is doubtful if the author means literally what he says. What evidence has he in favour of the view he has expressed? I am not aware of any observations by Dr. Bennett, or by any other observer, which tend in any way to show that the ovum is formed by the *coalescence of the molecules of the ovary*, or that spermatozooids and germinal vesicles disintegrate to form *molecules*.

Again, under the head of "practical applications," Dr. Bennett says,—"*The molecular theory must ultimately constitute the basis for the arts of horticulture, agriculture, and medicine. Thus, vegetables and animals grow by the juxtaposition of molecules which are introduced into the economy in the fluid form. This fluid holds in solution the particles of which the different textures consist. These are deposited, and so increase of bulk takes place.*" It would seem that every sentence here requires further explanation; and I can see no logical connection between the first and those that succeed it.

Dr. Bennett, not content with publishing his own doctrine, asserts that by his view several conflicting theories are reconciled, and at once proceeds to combine ideas which are quite incompatible with each other. He accepts completely contradictory statements, and himself makes assertions so opposite to each other, that both cannot be correct.

If vegetables and animals, as Dr. Bennett asserts, grow by the juxtaposition of molecules, such molecules must exist as positive particles. If in solution, they are no longer molecules. Dr. Bennett must accept his own definition of a molecule as "*a minute body seen*," "*a visible molecule*;" or he must admit, with other observers in the present day, that living matter absorbs substances in solution, and converts these into matter of the same, or into matter of a different, kind. If the matter is in a state of *solution* when it comes into contact with the living mass there can be no *juxtaposition of molecules*, and Dr. Bennett agrees in this matter with other observers.

With regard to the formation of vibriones, Dr. Bennett says that his assertion that molecules united to form the minute filaments is an inference, like my statement that the particles divided. The latter is a fact generally admitted by observers here and on the continent, and to be *seen* in whole classes of organisms. The former is a statement, in making which, I believe, Dr. Bennett stands quite alone.

Dr. Bennett says living organisms may be formed in one way, and multiply in another;—"Having been produced by precipitation, they may increase by absorption or imbibition of nutritive fluids." Now there is, in such a number of cases, incontrovertible evidence that a living mass does increase in size by the absorption of nutritive fluid, and that it does multiply by a portion of the living matter becoming separated, or moving away from the general mass, or by the division of the mass into two parts, that we are quite justified in concluding that living matter *always* increases in the same manner, and living particles *always* multiply in the same way.

There is, therefore, no reason for assuming that molecules become aggregated together to produce nuclei and cells, for the observed facts can be accounted for in a much more simple manner. That living matter always increases by absorbing nutritive pabulum in a state of solution, and that every living particle springs from a preëxisting living particle, are generalisations justified by observation.

I shall conclude this paper by drawing attention to Dr. Bennett's observations upon the use of high powers. Since many of the drawings and observations now being published by Dr. Bennett were made, vast improvements have been carried out in microscopes and magnifying-glasses, and new methods of observation have been introduced. Dr. Bennett maintains that in rare cases only has he gained any advantage by using powers varying from 700 to 1200 linear. I would simply observe in answer to this—

1. That it has been proved that points can be seen by the use of high powers which are not visible by a power of 250 diameters, and I shall be happy to show specimens in proof of this assertion to any one.

2. It is a fact, that for purposes of class illustration a power of 700 linear can be used quite readily. Objects under such a magnifying power were seen by classes of upwards of one hundred persons in London nearly two years ago.

3. There is no difficulty in proving that, by the use of very high powers and special modes of preparation, facts bearing in a most important manner on the mode of growth and multiplication of living particles can be demonstrated which cannot be seen

with powers in ordinary use; and there is every reason to believe that by improved means of inquiry new and valuable facts will be elicited.

The difference in mere dimension may be illustrated by the following figures of the same circle variously magnified; from which it must be obvious that the higher degrees of enlargement must give a clearer insight into the most minute recesses of structure than the lower powers used by Dr. Bennett, it being understood that the loss in definition bears no proportion to the augmentation of area.

Molecules less than the 1-6000th and 1-20000th of an inch, magnified 250 linear.

Molecules of about 1-4000th and 1-20000th of an inch in diameter, magnified 700 linear.

Molecules of the 1-4000th and less than the 1-20000th of an inch, magnified 1800 linear.

Molecules of the same diameter, magnified 3000 linear. The engraver has made the smaller circle too wide by nearly one-third of its diameter.

Vibriones, magnified 1700 linear.

Vibriones and vegetable growths in epithelium of the mouth, magnified 3000 linear.

The one-thousandth of an English inch, magnified 250 linear.

The one-thousandth of an English inch, magnified 5000 linear.  
This line should have been exactly three inches in length.

It is only just to Messrs. Powell and Lealand that I should state here most distinctly that the high powers made by them, and magnifying from 1700 to 1800 linear with the low eye-piece, are thoroughly practical working glasses. That extremely delicate instruments of any kind rather confuse and discourage than assist those who are just beginning to learn, is certain; but this is no argument against

their use by those who have been working for years. Better and higher powers and improved processes of preparation are clearly the means by which alone this branch of inquiry can be advanced.

Now, if molecules have united to form the vibriones represented in the last figure but one, the molecules were *certainly invisible* even to a power of 3000 diameters. The smallest of these organisms is less than the 1-100,000th of an inch in diameter. Particles considerably larger than this are quite invisible under a power magnifying 250 linear. It is certain, therefore, that if this particle were formed by the aggregation of smaller particles, these must have been quite invisible by the powers employed by Dr. Bennett; and since I can at least prove by direct observation that living particles of this size (1-100,000th of an inch in diameter) *do not coalesce or become aggregated* to form larger masses (*compound molecules*), I may affirm that this process cannot occur in the case of particles so large as those figured by Dr. Bennett.

TRANSFORMATION OF UREA INTO CYANIDE OF AMMONIUM. M. Fleury effected this change (*Comptes Rendus*, t. lv., p. 519) by heating urea with an excess of bisulphide of carbon. The products were carbonic acid and sulphocyanide of ammonium ( $C^2H^4N^2O^2 + CS^2 = CO^2 + NH^4C^2NS^2$ ). He has not perfectly succeeded in forming urea from sulphocyanide of ammonium.

ALUMINIUM BRONZE. In the supplementary number to vol. xxiv of the *Philosophical Magazine*, just published, is an article by Lieutenant-Colonel A. Strange, on the properties and present value of aluminium bronze, an alloy consisting of ten parts of aluminium and 90 of copper. Its tensile strength is stated at 73,185lbs. per square inch, being more than double the breaking-strain of gun-metal, and 1,185lbs. more than the average tenacity of cast steel. Its resistance to compression is 132,416lbs. to the square inch; that of cast iron being 115,542lbs. This alloy may be drawn out under the hammer almost to a needle-point at a red heat. Its rigidity is about three times that of gun-metal, and 44 times that of brass; it is less affected by change of temperature than either of the latter; it may be cast with extraordinary facility into any shape; it does not clog the file, and yields fine elastic shavings on the lathe. It tarnishes much less readily in the air than any other metal or alloy used for astronomical instruments, and will receive the finest graduation possible. It is extremely elastic, can be rolled into sheet metal, or also hammered and drawn, and seems admirably adapted for the tubular parts of astronomical instruments. Its specific gravity is 7.680, nearly the same as that of wrought iron. To make this alloy extremely pure, copper should be used; the best is copper deposited by electricity; but since that kind is very expensive, the next best is copper from Lake Superior, which makes an alloy of excellent quality. The ordinary coppers of commerce generally fail, owing, it is said, chiefly to the presence of iron, which appears to be specially prejudicial. Another precaution is to remelt the alloy two or three times. The first melting, in the proportions above stated, produces an alloy of extreme brittleness; but each successive melting, up to a certain point determined by the working, and particularly the forging properties of the metal, improves its tenacity and strength. The present price of English made 10 per cent. aluminium bronze is 6s. 6d. per lb., or four or five times the price of gun-metal; but as a much smaller quantity of the new alloy would give the same strength, the cost of ordnance made of it would not be very considerably increased. (*Galignani's Messenger*.)

# Addresses and Papers

READ AT

## THE THIRTIETH ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

[Held in LONDON, AUGUST 5th, 6th, 7th, and 8th, 1862.]

### OBSERVATIONS ON THE OCCURRENCE OF MALIGNANT PUSTULE IN ENGLAND: ILLUSTRATED BY NUMEROUS FATAL CASES.

By WILLIAM BUDD, M.D., Clifton; Honorary and  
Consulting Physician to the Bristol Royal  
Infirmary.

"Le médecin doit, dans ses premières études, jeter un coup d'œil  
sur les animaux qui se rapprochent le plus de l'homme."—*Chaus-  
sier*. (Adopted from Régnier.)

[Continued from page 113.]

CASE V. The notes of this case were kindly given to me by my friend Mr. Humpage of Cotham, who attended the patient.

"Mrs. S., aged about 40, married, the mother of three children, and of what is called the leucoplegmatic temperament, had complained for several days of a pimple on the chin, which, becoming troublesome, was seen by a surgeon three days before I was first called to her.

"I first saw her on Oct. 12th, 1855, in the evening, and found the following state of things:—On the chin a puffy tumour, with a livid spot on its apex; great surrounding swelling and infiltration of the cellular tissue of a hard and unyielding character, difficult deglutition, and much constitutional disturbance, indicated by a very low and rapid pulse, and general exhaustion.

"On the following morning, finding all the symptoms much aggravated, I advised a consultation with my friend Mr. Green. We agreed the case was one of the most imminent danger. A free incision was made through the parts; but they cut like brawn, *dry and solid*. The patient was directed to take brandy freely; but she rapidly sank, as if poisoned, about twelve hours after the incision, and in about thirty hours from the time of my first seeing her."

I have been informed by the husband of this person that for the first three days there was no general illness; nothing, in fact, to lead him to suppose that the malady from which his wife was suffering was any other than a common boil. It began as a minute vesicle, which the patient punctured with a needle on the day following that of its first appearance, and it was her own impression that in this operation she had poisoned the flesh. The vesicle was attended by intense itching when it first appeared.

In some notes of the same case communicated to me by Mr. Green, it is mentioned that when the incision was made, nothing but a little serum slightly tinged with blood oozed from the wound.

CASE VI. For the knowledge of this case I am also indebted to Mr. Green, in whose words, for the most part, it is related.

On June 18th, 1858, late in the evening, I was sent for to see Miss S., living about seven miles from Bristol. Her father, who drove in for me, told me that a few days before a pimple appeared on the lip, followed by enormous swelling, discoloration, and stony hardness. She was, he said, frightfully disfigured. His account left me little doubt as to the nature of the disease I was to find; and I told him that I feared his daughter was suffering from malignant pustule, an uncommon and most dangerous form of disease.

I found the left half of the face principally affected. It was swollen through its entire extent; the lips were greatly enlarged, indurated, and everted. The skin was of a dark, livid colour. There was a small pimple covered by a thin, hard, dry crust on the left side of the upper lip, which was indurated to the extent of about an inch above its margin. The lower lip on the same side was in a state of slough. Sloughing had also begun at the angle, and was extending backwards into the mouth, under the skin, which had not yet lost its vitality. The eyelids were closed; but the swelling there being œdematous, allowed the eye to be examined. This organ was found to be uninjured. The pulse was 120 in the minute; the tongue was foul. There was, however, no delirium or loss of consciousness, and no particular complaint of weakness or depression. The swelling and colour of the face, and the large projecting lips, caused great disfigurement, and removed all doubt from my mind as to this poor young lady's fate.

The disease had first appeared three days before, in the form of a small vesicle, which itched very much, and which the patient herself punctured with a needle the same night. This operation, as in most of the other cases, was followed by great temporary relief to the pruritus. This young lady had spent the greater part of the day in the hay-field, and while there was, as she believed, bitten by a fly. It was in the seat of the supposed bite that the vesicle afterwards appeared. The next day, the face began to swell and change colour; and from that time the disease progressed rapidly, until it had attained the stage in which I now saw it. The right side of the face did not participate in the swelling, but was of a sallow and yellowish tinge. On the second day of illness, the part in which the pimple first appeared having become black, Dr. Vaughan of Keynsham, who was in attendance, made an incision into it. Poulices had been applied to the face, and quinine and iron given internally.

A strong solution of chloride of zinc was now applied to the sloughing surface, and, in place of the quinine, dilute nitromuriatic acid was given every three hours. Wine and strong beef-tea were freely exhibited.

On the following day, there was little change, except that the sloughing had considerably extended.

On June 20th, soon after daybreak, she became rapidly worse. The pulse could hardly be felt; the extremities were cold; she was unable to swallow; and the entire cheek seemed about to sphacelate. She died at noon of the same day, five days after the first appearance of the vesicle, which, in its origin, had seemed so trivial.

This young lady had been somewhat out of health for some months prior to the fatal attack.

CASE VII. For the particulars of the next case, I am indebted to Mr. Bartrum of Bath, and Mr. Hinton of Hinton, who was nearly related to the patient.

The subject of it, W. H. W., was a fine, well-grown, and athletic young man, 19 years of age, who, up to the date of his attack, had enjoyed uninterrupted health.

On October 7th, 1859, he returned from Clifton to his home near Bath, with a painful and swelled lip. The disease had begun the day before in the form of a small vesicle seated on the left half of the upper lip. Whether the itching and hot stinging sensation which usually mark the onset of the malady were present is not said.

On his reaching home, the appearance of the lip led his friends to suppose that a boil was about to form in it. He complained a little of pain in the back, and seemed slightly feverish; but, beyond this, did not feel ill.

On the 8th, the swelling had increased; but, with the exception of a general dingy appearance, there was no local discoloration. On the nights of the 8th and 9th, the tension and pain of the lip were so great as to prevent sleep.

On the evening of the 10th, he took a slight sedative, had a good night, and never after suffered from pain.

Up to this time, nothing had occurred to awaken the minds of the patient or his friends to the terrible nature of the attack, which they still supposed was nothing more than a painful boil.

On the 10th, the swelling extended to the neighbouring parts; the inner surface of the upper lip became livid, almost black, "but without any defined boundary, as though a large carbuncle was forming on the inner surface."

On the 11th, the parts were freely and very deeply incised (from within), with much relief to the symptoms. The cut surfaces presented streaks of dingy yellow, interspersed with dark, livid, bloody, sodden tissue. The blood was thick and treacly. There was no pus.

On the 12th, the swelling occupied the whole face below the eyebrows. The incisions were repeated in several parts that felt brawny, and appeared to give much relief. The pulse had gradually become more rapid, ranging from 140 to 160 in a minute.

The mind remained perfectly clear until about four hours before death, which occurred at midnight on the 14th, eight days after the first appearance of the vesicle. In the second period of the disease, several new vesicles made their appearance in the neighbourhood of the first. Beef-tea, wine, and other nutriment, were given liberally throughout. The patient was unable to assign any cause for his attack.

For the following brief, but clear and graphic, account of the next two cases, I am indebted to my friend Dr. S. H. Steel of Abergavenny. They are extremely interesting, as examples of the disease originating in the hand.

CASE VIII. "While paying my usual visit at an iron-work, four miles from my house, I was requested to see Mary John, the daughter of an innkeeper, a tall, healthy, well developed girl, aged 19. She stated that two days before, a red spot, attended by pain and itching, had appeared on the back of her right hand. The redness had extended, and was now very painful.

"I found on the back of her hand a rather irregular, livid spot, half an inch in diameter, surrounded by an erysipelatous blush; deep near the centre, and gradually shading off till it ceased half way up the forearm. The hand and arm were swollen, but not greatly so. The pulse was small and frequent; the tongue was slightly coated and moist; the bowels were confined. She complained of great depression. The treatment ordered was a large warm fomentation to the hand and arm, and an aperient, followed by a stimulating mixture.

"The next morning, I received a message that she was much worse. I saw her at 11 A.M. The livid spot had spread over the whole of the back of the hand and wrist. The swelling of these parts had rather subsided; but the whole arm was oedematous, and the erythema extended to the axilla and side of the chest. The pulse was very frequent and feeble; the tongue was still moist. She was sensible, and answered readily in a feeble voice, but was evidently moribund from prostration. I made two or three free incisions into the livid and adjacent oedematous parts. No blood, but only a little colourless serum, exuded, and no pain was felt. The appearance of the part was very peculiar. The lividity was less deep than that of ordinary gangrene, and shaded off into a dusky erythema, the oedema being greater as it receded from the central disease. The patient died at 2 P.M.

"I was convinced, from the whole aspect of the case, that it was one of some form of animal poisoning, and I made careful inquiries, especially whether any glandered horse had lately been in the inn stable; but I was unable to discover any clue to the cause of the disease."

CASE IX. "On January 2nd, 1854, I was sent for to

see Morgan Jones, a labourer, aged 34, living about four miles from Abergavenny. He told me that five days before a red, irritable spot had appeared on the back of his right hand, which was chapped in several places from cold. The redness and pain had gradually increased; but he had paid little attention to it till the day before, when he felt very weak, and was unable to go to work. I found the back of the hand livid, and the arm red and oedematous, presenting an appearance precisely similar to that observed in Mary John's case. An incision through the livid part let out only a little serum. The pulse was small and frequent; the tongue was brown and furred, and had been so for a day or two. The man was perfectly sensible. An energetic stimulant treatment was adopted, but the case was evidently hopeless. It terminated fatally the following day. There was no history of animal infection that I could trace. The patient had been employed in tending sheep; hurdling them, and supplying them with cut turnips; but I could not ascertain that the sheep were unhealthily.\*

"I was much perplexed by these two cases. I had no doubt of their animal origin; but they did not answer to the description of glanders, to which I was at first inclined to refer them.

"Some time afterwards, I was asked by my father's farm-bailiff to look at two lambs which were diseased, and likely to die of some strange complaint. The hinder extremities of both were greatly swollen, and inside the thighs, where the wool is scanty, the skin exhibited the same livid aspect that I had observed in my two patients, and upon cutting into it, the same discharge of serum only took place.

"I had no doubt that I had before me an identical or very closely allied disease. I did not, however, recognise it as malignant pustule, till I heard you relate your cases of that malady. The pustule, which is described as the point of departure of the disease, either did not exist in my cases, or, more probably, was overlooked."

This history, brief as it is, is a very pregnant one. It brings into striking relief a point on which I have not before touched, but which is very important; I refer to the perfect identity of the local morbid changes in the malignant pustule of man, and the corresponding disease of the animal. I need scarcely say to those who are acquainted with the subject, that these two lambs were suffering from the disease familiarly known to veterinarians under the name of "blood," and identical in nature and origin with the "quarter evil" in cattle. Both lambs died in the course of the day in which Dr. Steel first saw them.

In addition to the cases already related, I have obtained, as I have before said, some particulars of no fewer than fifteen others, which have occurred, for the most part, within the last few years in various parts of the country. It may be mentioned, as a remarkable fact, that in all fifteen—as in seven of the nine just detailed—the disease began in the face, and in the greater number, either in the lip, or in the immediate neighbourhood of the mouth.

In all, save one, in which life was apparently saved by early resort to cauterisation and free incisions, the malady ended fatally. In all, save this same one, its seemingly trivial nature in its early stage betrayed the patient into the fatal error of wasting in mere temporising the only period in which curative measures are of any certain avail.

Of the whole series there was only one in which the disease was actually traced to contact with a diseased animal. In its bearing on the question of cause, the history of that case is not unimportant.

A pointer belonging to a gentleman who was out part-

\* It is worthy of remark that in both these cases the disease was seated on the back of the hand. This is the usual seat of malignant pustule in the hand. It is obvious that, from the greater thinness of the skin, this part is more exposed to an effective inoculation.

ridge shooting, fastened upon the carcase of a sheep which lay dead in a field, and took possession of one of its legs. The morsel was so savoury that the dog would not give it up, and his owner was obliged to wrest it with his own hand from the animal's mouth. Immediately afterwards, this gentleman, unthinking of danger, mechanically put his hand to a part of his face where there was a scratch. On the following day, a malignant pustule made its appearance on the very spot to which the tainted hand had been carried. The disease of which the sheep had died was not ascertained. The dog received no harm.

The circumstances of three other cases are also worth mentioning. One of the subjects was a bullock-jobber, who at the time of his attack was carrying on large dealings in cattle; and another was a sheep-farmer living on the borders of Dartmoor, who owned and tended very large flocks. Although in these two the actual source of the disease was not made out nor indeed inquired into, there is no improbability in the supposition that the pustule might have arisen from contact with cattle or sheep affected with quarter evil or blood.\* It is not irrelevant to observe that both these cases occurred in hot summer weather. I may add that the subjects of both were more than fifty years old.

In a third case, the pustule was undoubtedly the result of the bite of a fly. The patient—as in the similar case already related—was a young lady who was attacked by the insect while she was walking in her garden on a hot summer's evening. The itching, heat, and burning of the first stage succeeded immediately to the bite, and in the course of a few hours the characteristic vesicle made its appearance in the exact seat of the puncture. The case was the most rapidly fatal that I have yet heard of.

## HOSPITAL PRACTICE:

METROPOLITAN AND PROVINCIAL.

BIRMINGHAM GENERAL HOSPITAL.

CASES OF RHEUMATIC PERICARDITIS.

Under the care of JAMES RUSSELL, M.D.

[Continued from page 137.]

THE following case was not under my care; but I had the opportunity of watching it throughout. It exhibits the treatment of pericarditis as employed twenty years ago.

CASE II. J. R., aged 21, a baker, came under treatment February 8th, 1843. He had been exposed to sudden alternations of temperature. Seven years previously he had acute rheumatism, accompanied by dyspnoea, præcordial pain, and palpitation; but no symptoms of cardiac disorder remained on the subsidence of the attack. The rheumatism returned in January 1843, together with the pain, dyspnoea, and palpitation. The pain was felt very severely over the entire chest, but especially in the cardiac region, and with it there was a short dry cough. On the date above indicated, all the rheumatic symptoms were subsiding; the pulse and respiration were nearly natural; the thoracic pain alone remained. He was cupped to twelve ounces over the region of the heart; three grains of calomel and a black draught were given; and one-twelfth of a grain of tartar emetic and five grains of nitrate of potash in saline mixture every four hours.

It was not until three days afterwards (Feb. 11), that any record of the physical examination of his chest was made. The cardiac dullness extended to the third rib; but not to preternatural extent in any other direction; and a soft systolic mitral bellows-sound, and a faint diastolic blowing sound at the base, were audible. The symptoms described above, especially the severe pain over the left side of the chest, continued, and respiration had become accelerated. Fourteen ounces of blood were taken from the arm, with the effect of causing faintness, but not of affording relief; and on the 12th, six leeches were applied.

On the day after (13th), the pulse and respiration were 108 and 44. The pain was severe. There were pallor and much exhaustion, with considerable increase of the rheumatic pain in the limbs. His cough was troublesome. A distinct friction-sound had now announced its presence. He was cupped to fourteen ounces.

On the 14th, the distress from dyspnoea and pain was augmented. The pain extended over the entire part of the chest, with an intolerable sense of compression; and movement so much aggravated the pain that the patient's posture was fixed; to the pain was added a harassing cough. The pulse and respiration were 124 and 56. To the friction-sound, evidence of large effusion was superadded; the cardiac dullness extending across the middle third of the sternum for two or three inches into the opposite side. He was ordered to repeat the leeches; to employ inunction of mercurial ointment; and to take a grain of calomel and two grains of Dover's powder every four hours.

The following day presented further aggravation of the symptoms, gasping breath and a ghastly aspect of face, indicative of great distress. The pulse and respiration were 25 and 60. His intellect was entire. The pain unrelieved. Leeches were repeated, and the dose of calomel raised to two grains, the inunction being also continued. The effect of each bleeding was only to induce faintness without affording relief to the pain or to the breathing. The patient passed a wretched night; and on the 16th, his aspect was most distressing. He could not utter a continuous sentence from breathlessness, which he endeavoured to relieve by frequent change of posture; exhaustion had increased; the face was ghastly; the lips livid; but the intellect remained unclouded. No sign of salivation had announced itself. The physical signs were unchanged.

In the afternoon, he was sitting up in his bed, when he suddenly fell back dead, on the fourth day from the first appearance of physical signs of pericarditis.

SECTIO CADAVERIS, twenty-four hours after death. The pericardium contained a considerable quantity of bloody serum. The outer surface of the heart and the inner surface of the pericardium were thickly coated with soft lymph; in many parts, of a deep blood colour, especially posteriorly. The layer of lymph was thicker posteriorly than in front; it could be easily removed, leaving the serous membrane smooth. A large *tache blanche* existed on the apex of the heart; and several others on the posterior surface. The heart was adherent to the pericardium by soft lymph, at the apex, along the right border, and at the posterior part of the base; it was hypertrophied; its muscular tissue was pale. The aortic flap of the mitral valve was thickened at its edges; the parietal flap was much contracted. The lining membrane of the left auricle was opaque and rough; and that of the right auricle was also somewhat roughened between the orifices of the cava. Both ventricles and the right auricle were much distended with coagula, partly recent, partly of pure fibrine. Each pleural cavity contained some straw-coloured fluid; and the substance of the lungs was greatly congested, scarcely crepitating anywhere. Some subpleural emphysema existed at the acute margins.

\* The same remark applies to one of Dr. Steel's cases.

It is of the utmost importance in pericarditis correctly to estimate the amount of power possessed by the heart; both as a guide to the selection of remedies, and as affording a basis for prognosis. Among various circumstances which may create difficulty in accomplishing this, none are harder to deal with than extreme nervous susceptibility on the part of the patient. Every practical man knows well what an unfavourable influence is exerted upon the symptoms and progress of organic disease by a morbidly excitable or hysterical temperament; how every symptom is intensified and disguised; how the action of remedies is perverted, and the influence of active disease exaggerated. Every one, too, is aware of the peril of encountering a sudden and fatal termination to a case of disease under such circumstances; a termination often due simply to nervous depression.

But in no class of cases do these difficulties and dangers exist in greater force than in those which relate to the heart, and especially in cases of active inflammation of that organ; for no organ is so liable to be injuriously affected by nervous depression or excitement as the heart.

I quote the following case in illustration. I am still ignorant what is the precise share of blame to be given to the inflammation, and what to the very sensitive temperament of the patient. I more than once congratulated myself that my case occurred in hospital practice, and not at the patient's home.

CASE III. Emma Piper, aged 17, a servant, was admitted Oct. 20th, 1862. Her first attack of rheumatism occurred in March 1861; she was not free of the disease till after Christmas. Her present attack (the second) set in about the middle of this month. She had always lived well. Her menstruation had been irregular. Both parents were rheumatic, and she lost a brother in this institution of rheumatism.

On October 22nd, she was noted to be of full habit and of very moveable temperament. The pulse and respiration were 120 and 40; she had rheumatic inflammation of most of her joints, excepting those of the left arm, and she also complained greatly of her back. She perspired much. The tongue was covered with white fur. Half a scruple of Dover's powder given on each of the preceding two nights had failed to procure sleep. The sounds of her heart were clear. She was ordered eight minims of tincture of opium, with bicarbonate of potash every four hours, and half a scruple of Dover's powder nightly.

She continued in much the same state until the 25th. The rheumatic affection had extended to the left arm; the opium had failed to relieve the pain and the restlessness. On the 25th, she had much improved; and the rheumatism was subsiding. The pulse and respiration were 128 and 44. Her urine was neutral. The sounds of her heart were still normal.

In the night, however, pericarditis developed itself. In the morning, the pulse and respiration were 136 and 50; and the face manifested a tendency to lividity; the jugulars also were rather full. *Fremissement* was felt in the region of the third costal cartilage, and a double friction-sound was heard over the upper part of the cardiac region; the cardiac dullness included the third interspace. Eight leeches were ordered to be applied to the chest; and the entire left chest to be fomented.

On the 27th, the rheumatic affection was rapidly subsiding; but the patient had passed a bad night. Her face was pallid, and her aspect indicated great distress. She complained much of a paroxysmal pain in her back, rising to her throat, and especially excited by drinking. Her respiration and the action of her heart underwent remarkable variations. At one time, she breathed or rather panted at the rate of 80 per minute; her face was pallid; and the action of her heart became, at the same time, so feeble that the rubbing-sound was almost inaudible; yet, in a short time, respiration fell to 40; the ab-

normal sound at the heart was again distinct, and colour returned to her face. The *frottement* could no longer be distinguished; her jugulars were free from distension. The pulse was about 136; steady, though rather collapsing. Her abdomen was much distended, and she complained of much pain in that region. A turpentine stupe was ordered to be applied to her chest. She was directed to take every three hours eight minims of tincture of opium and a drachm of compound spirits of sulphuric ether; and to have half an ounce of brandy every three hours.

Her condition in the evening appeared more perilous; the distress was great, the intellect clear, face leaden. The pulse and respiration were 132 and 60. The region of dullness extended from the right edge of the sternum to the nipple, and upwards to the third rib. A blister was applied. Brandy was given every three hours, and the opium was omitted.

During the following two days she improved; and on the 29th, a remarkable disappearance of the entire cardiac dullness was noticed, though on the preceding day it had occupied wider limits than those indicated above. Quinine had been substituted for the stimulant, and the brandy was given every three hours.

On the 30th, she seemed in comparative comfort; yet, in marked contrast, her respiration was 60. The friction-sound was faint, but general.

Again, on the 31st, distress reappeared; respiration still taking the lead, rising to 76, in a succession of pantings with intervals between. Pulse 112 to 120, steady. Her complaints were vehement, and her impatience of pain very great; but, after an interval, the excitement subsided, and she became calm. The cardiac dullness had regained its former limits. Diarrhoea was also present. She was ordered eight minims of tincture of opium and sixteen minims of chloric ether three times a day.

Through eight days from this date, she steadily mended, though still liable to excitement. But on Nov. 9th, the period when the poor girl the subject of the first case, who occupied the next bed, was undergoing her fatal relapse, the patient was found with return of all her former symptoms with great intensity. I now discovered some dullness at the right base; but though some amount of pleurisy might be chargeable with the recurrence of the disturbance, yet experience of her extreme irritability, together with some evidence that her symptoms increased in intensity at the time of the visit, and the evidently depressing influence of the nervous perturbation which she permitted, suggested the necessity of full doses of opium; and, accordingly, with a blister to the right side, sixteen minims of the tincture with an equal dose of chloric ether were ordered to be taken every three hours. The medicine had a decided, but only temporary, beneficial influence. Again we were met with recurrence of all the symptoms, and as the influence of imitation was now clear, from her unfortunate neighbourhood and attendant circumstances, the effect of decided rebuke and firm remonstrance was tried. A hysterical attack was the consequence, and she remained in a decidedly hysterical condition till midnight, when she fell asleep, and from that time progressive amendment might be dated.

It should be added that the pleurisy gave no further trouble. On Nov. 25th, the patient was permitted to leave her bed, and had the appearance of health.

As if for the purpose of establishing a violent contrast, at the time I was treating the preceding case, the subject of the following notes was admitted into the hospital.

CASE IV. (Mr. Hiron.) John Holland, aged 14, a brass-founder. When examined, the day after admission, his face was tranquil, well-coloured, and presented the aspect of health, though he admitted that he had lost flesh during his illness. Pulse 102; respiration 16. He

was perfectly free from pain, intercostal tenderness, and cough, and was not conscious of any trouble in breathing; slight deficiency, however, was observed in the expansion of the left side of the chest. His joints were quite unaffected; and he was with difficulty induced to enter the hospital; and, when in, was most unwilling to keep his bed. His urine was very acid, and deposited a cloud of pink urates; in all other respects it was normal.

Cardiac dulness extended upwards to the second cartilage; laterally it reached from the left edge of the sternum to the nipple. A remarkably loud and superficial pericardial friction-sound was heard over the heart; it was indeed one of the loudest rubbing-sounds I ever heard; very coarse, recalling to one's mind the action of a large saw; although so loud over the whole region occupied by the heart, it became inaudible at a very short distance from that region, excepting that it was distinct in the left subclavian space. The pulmonary sounds were normal.

The patient's history was as follows:—Both parents and eight brothers and sisters were all free from rheumatism. The patient had never suffered from rheumatism previously to seven weeks before admission, when he caught cold from bathing. A week afterwards, he was attacked with severe pain in his knees without swelling, for which he kept his bed three days. No other joint was implicated; and three days after leaving his bed he returned to work. Again, a week afterwards, he suffered pain in his left side; which, however, was not constant, and only kept him at home half a day. At the end of another four days, this pain returned with greater severity, and on this occasion he remained from work two days. A fortnight's respite followed, when the pain recurred, but in a milder form; and on the evening of the ensuing day, he was brought to the hospital, the pain having ceased, and the patient rebelling violently against being considered an invalid. During these several relapses, his joints remained free; but he had symptoms of catarrh and coryza.

No fresh symptoms presented themselves during his residence in hospital; he seemed in good health. Nevertheless, no change occurred in the physical signs for twelve days, saving some reduction in the extent of the heart's dulness. At the end of that time he was allowed to get up; and the next day but one, dulness had assumed nearly its normal dimensions, and the friction-sound, though quite as loud, had become smooth. Three days afterwards, the sound was soft, precisely resembling a double bellows murmur, and was hardly distinguishable beyond a limited space in the upper part of the sternum. At the same time the cardiac dulness attained the third cartilage. In two days more not a vestige of friction-sound remained, though once it reappeared for a single day, accompanying the first sound of the heart only, and audible at the junction of the first and second bones of the sternum.

The patient was discharged on the twenty-seventh day, having already made two flights home. At that time cardiac dulness was extended laterally as far as the nipple, close to the fourth cartilage. The impulse of the heart had slightly a peristaltic character, and was rather heaving. The first sound of the heart was decidedly feeble; but there was no bellows sound.

The treatment consisted simply of a blister to the cardiac region with salines, and subsequently, four ounces of wine. Iodide of iron and cod-liver oil were subsequently prescribed.

This case forces on us the conviction how small a part of disease is embodied in the mere organic changes by which it may be accompanied, and how feeble is morbid anatomy, standing alone, as an exponent of pathological science. But a further question arises. Notwithstanding various means of discrimination, it is sometimes difficult, if not altogether impossible, to distinguish be-

tween an exocardial and an endocardial murmur; and such a case as the present may suggest that it may also become a question difficult of solution, whether or not we have to do with an acute attack at all; the more so, as Dr. Gairdner has given some instances in the essay quoted above, to prove that an exocardial murmur may sometimes be persistent, as is usually the case with an endocardial murmur.

The other day Dr. Maxwell drew my attention to a woman under his care as an out-patient. She had been in attendance for a week; she had nursed a son through an attack of rheumatic fever, and applied for relief in consequence of pain in the left hypochondrium. She made no complaint whatever referable to the heart, but on applying the stethoscope, Dr. Maxwell heard the sounds, much as they presented themselves to my ear. A week afterwards, a loud harsh systolic sound, quite superficial, was heard beneath the sternum, from the second cartilage to the ensiform cartilage, becoming, however, fainter just above the latter spot. It was scarcely heard beyond the limit of the sternum, but existed feebly beneath the right sterno-clavicular joint, though not up the carotids. The normal sounds of the heart were heard to the left of the sternum, though more feebly than usual. There was no extension of cardiac dulness.

The woman had never had rheumatism nor any cardiac symptoms. She walked to the hospital on each occasion.

I felt no doubt that the murmur was pericardial, from its situation, its limited extent, its superficial character, and its quality; but I certainly could not venture to assert that it was associated with acute development of inflammation. Unfortunately, the patient never returned.

[To be continued.]

NEW WORK ON THE BIRDS OF INDIA. Surgeon-Major Jerdon, of the Madras Army, who has a considerable local reputation as a Naturalist, is about to publish a work on the Birds of India, as the first of a series of Manuals on the Vertebrated Animals of India. (*Friend of India.*)

EIDER DOWN. This down, the eider-duck plucks from its breast to line its nest; it and the eggs are taken away. Again the nest is lined, and again robbed. The third time, the drake repairs it, supplying the down; and if this be also taken away, the nest is altogether deserted by the ill-used pair. One nest yields about two and a half ounces of the finest clean down, or about half a pound in all if removed three times. What is plucked from the dead bird, it is said, possesses none of that wonderful elasticity which constitutes the value of the other. We should think, however, that this would depend on the state of the plumage at the time. Many thousand pounds weight of it are annually exported for quilts, pillows, cushions, etc. It sells in Iceland at from 10s. 6d. to 17s. 6d. per pound. From three to four pounds are sufficient for a coverlet, which, to be enjoyed in perfection, ought to be used unquilted and loose like a feather bed. Quilting is only useful where a small quantity of down is required to go a long way; but, with three or four pounds at command, there is no comparison in point of comfort between loose and quilted—we have tried both. The eider coverlet combines lightness and warmth in a degree which cannot be otherwise obtained. With a single sheet and blanket, it is sufficient for the coldest wintry night. Its elasticity is proverbial; hence the Icelandic conundrum we had propounded to us by our good friend Mr. Jacobson, "What is it that is higher when the head is taken off it?" Answer—"An eider-down pillow!" (*Pen and Pencil Sketches of Faroe and Iceland.*)

### THE FIBROUS TUNIC OF THE EYEBALL, OR "OCULAR TUNIC": ITS ANATOMICAL RELATIONS AND BEARINGS IN OPHTHALMIC PRACTICE.

BEING REMARKS ON THE COURSE OF CLINICAL  
INSTRUCTION AT THE CENTRAL LONDON  
OPHTHALMIC HOSPITAL.

By HAYNES WALTON, F.R.C.S., Surgeon to the Hospital,  
and to St. Mary's, Paddington; late Teacher of  
Anatomy and Demonstrator of Operative Surgery  
in St. Mary's Medical School.

It may seem strange to say that, till lately, the anatomy of the ocular appendages was not correctly taught. An extensive and important membrane about the eyeball, concerned alike with operations and in the discrimination of disease, was not recognised in orbital dissections, but disregarded and taken away as so much cellular tissue to be cleared out, in order to render evident other anatomical relations.

Knowing how little this structure is understood, how scarcely it has been alluded to either by anatomical writers or surgical teachers, and seeing the importance of it, I shall make it the subject of a short lecture, describing the anatomy, and pointing out the influence it has in actual practice.

So long ago as the year 1804 Tenon demonstrated this ocular tunic, and called it the tunic of the eye. Like, however, many valuable hints in anatomy and surgery, it was forgotten for a long series of years, till a later recognition of it was declared a new discovery. Drs. O'Ferrall and Bonnet were the next to treat of it, each claiming the merit of originality. The former made his views known in 1841, in the *Dublin Journal of Medical Science*, and to him indisputably is due the merit of surgical and pathological application. Bonnet's notice appeared a year later.

I shall now give a description of this tunic, which has been also called tunica vaginalis oculi, cellular capsule, Bonnet's capsule, cellular sheath of eye, fibrous sheath.

It is a distinct tunic of a white colour and fibrous consistence, continuous in front with the posterior margins of the tarsal cartilages, and, extending backwards, adheres to the optic nerve as this penetrates into the sclerotic. With the sharp end of a probe, or of a director, it may be separated from the eyeball, by breaking the fine cellular tissue to which connects them. Within, it is smooth, facilitating the ocular movements; externally, it is loose and cellular. The muscular portions of the recti muscles lie at the outside, so that it insulates and protects the eyeball in the most perfect manner possible. Half an inch posterior to its front margin are six well defined openings, through which the tendons of the muscles pass to their insertions in the sclerotic coat, and over which they play as through a pulley, and get their force properly directed, securing rotation, and opposing retraction, which would otherwise predominate.

The readiest way of exposing the tunic is to cut through the palpebræ vertically, to turn back the separated parts, and to divide the conjunctiva at its angles of reflection from the internal surfaces of the eyelids to the ball of the eye.

How different all this is from the usually received opinion of the orbital muscles being in contact with the eyeball.

The first beneficial result of a proper knowledge of the tunic was the present improved manner of extirpating the eyeball, in which the conjunctiva is cut through close to the cornea, the recti and oblique muscles divided

at their sclerotic attachment, and the optic nerve severed within the tunic; so that the orbit is as it were left sealed in front by the membrane. This contrasts greatly with the old operation of dissecting away the whole of the orbital fat and cellular tissue, when it was desirable only to get away the eyeball, and not any of the appendages, an act that can scarcely be justifiable, except in the somewhat doubtful measure of clearing out the orbit for a cancerous growth. The difference in the severity between the two processes and the after effects is great indeed. In the one, there is no shock to the system, and the patient is scarcely invalidated, and the effect passes off quickly in one or two days. The orbital vessels and nerves are left intact, and there can scarcely be any bleeding. The extent of the other, the hæmorrhage, the general bodily disturbance, and the somewhat risk, are well known.

The better result in the operation for internal squint is also to be ascribed to the recognition of the ocular tunic. Formerly a very free dissection was made at the inner corner of the eye, and unfrequently the tunic detached from its connection under the supposition of being "adhesions" that needed disconnection. The common issue of such mal-operating being frightful eversion of the eyeball with prominence. We now know how essential it is, in order to secure the correct ocular movements, that the divided muscle should acquire an attachment as near the natural spot as possible, through one or other of the four or five processes that *post mortem* inspection has revealed to us, and which is beyond the range of possibility, if the parts in connection, especially the tunic, be much cut and displaced. I think, too, that prominence scarcely, if ever, occurs to any marked degree, when the tunic is not interfered with.

Another addition arising out of this knowledge, is the greater facility and accuracy afforded in the removal of orbital tumours. As it is not in the plan of these remarks to give the detail of cases, I shall not cite instances. Suffice it to say, that it greatly furthers the execution of such operation, whether the growth be solid, or encysted. I have on many occasions been able to proceed with more confidence, better to avoid parts not involved in the disease, and to get superior results. I may mention that these morbid products may grow outside the tunic, on it, or within it. It should be the object of the operator, in every instance, to preserve the tunic as intact as possible. On one occasion, while removing a fibrous tumour from the upper part of the orbit that had cellular connections to the vestment, I was enabled by slow and careful scratching with the point of the scalpel, rather than cutting, to get the whole away without damaging it.

The position of abscesses in the orbit, and their relation to the eyeball, can be better understood, and therefore, the evacuation of the pus more surely accomplished. When a student, I was taught always to keep the instrument, used for such a purpose, towards the wall of the orbit, lest the eyeball should be wounded. But if this be adhered to, how is the abscess to be got at when it is within the tunic. With the commonest care when here, it may be evacuated without the least risk. I have relieved several patients after other surgeons, not cognisant with the anatomical matter in question, have failed to find the pus.

To Dr. O'Ferrall is due, too, the credit of recognising rheumatic inflammation of the ocular tunic; and, with his accustomed ingenuity and accuracy, he makes the anatomy of the eyelid available in the diagnosis. He shows that under the orbicularis muscle is a distinct layer of fascia, and that this is the first element of the eyelid that enters the orbit; that there is another layer of fascia beneath the levator palpebræ, which also enters it, and uniting with that above, forms a sheath for the accommodation and support of the muscle; and he points out the attachment of the ocular tunic to the orbital margin of the tarsal cartilages. This anatomical

arrangement he then traces on the outer surface of the eyelid in the two portions separated by the natural fold of the skin, the upper portion constituting about one-third of the surface of the lid, the lower the remaining two-thirds. From these he makes the pathological deduction, that certain forms of disease within the orbit that are seated in, or internal to, the motor apparatus—that is in the substance of, or within the cavity of the ocular tunic, extend their effects to the lower portion of the eyelid, with which they are continuous, and that certain other affections situated external to the motor apparatus—which is that part of the orbit containing the fat—will show themselves by inflammation or other changes in the upper division of the same.

The last subject to be noticed in connection with the ocular tunic, is the greater light that Dr. O'Ferrall has been able to throw on the causes that protrude the eyeball. Inflammation of the ocular tunic will in itself cause ocular prominence. This is chiefly through effusion into the cellular membrane connecting it to the ball of the eye. The infiltration is apparent where the conjunctiva is reflected from the eyelid to the eyeball, just where this membrane closes up the ocular tunic in front. Here it receives the pressure of the effused serum, and becomes separated from the sclerotic coat by the extension of the infiltration. The amber coloured chemosis, originating in inflammation of the conjunctiva, is distinguished from it by redness as well as serous infiltration.

### ON THE USE OF NITRIC ACID IN THE CURE OF ULCERATION OF THE OS AND CERVIX UTERI.

By HANMETT HAILEY, M.R.C.S.Eng., formerly House-Surgeon to the Midland Counties Lying-in Hospital.

At a meeting in 1862 of one of the leading London medical societies, the subject of discussion was the value of nitrate of silver as an escharotic in cases of ulceration of the os and cervix uteri. Having for years past had extensive experience in the treatment of uterine disease, and tried the various kinds of applications in general use, both fluid and solid, and finding but one upon which I could rely in producing permanent amelioration of the disease, viz., pure nitric acid,—I will select from my notebook a few well-marked cases of ulceration in its various stages, from the phagedænic down to simple excoriation, that have not only been cured, but have borne inspection some years afterwards, and have never in a single instance in my practice shown a tendency to return—a fact that cannot be induced in favour of nitrate of silver, or any other solid, or, I believe, fluid, caustic application now in general use.

My nomenclature of diseases affecting the os and cervix uteri is, like the treatment, simple: 1. Cases of cancerous ulceration, or disease with apparent malignant tendency, where the ulcer is large, excoriated, discharging pus or matter of a mucopurulent character, in conjunction with great derangement of the general health—in fact, every symptom of cachexia; 2. Cases of simple ulceration or excoriation, with or without hypertrophy, accompanied by symptoms not quite so distressing to the general health. I will detail a few cases of each variety; and then offer some remarks on the relative value of the various applications, solid and fluid, generally employed in the treatment of ulceration situated about the mouth of the uterus. Of the first variety, or cases of an apparent malignant nature, I have selected three examples.

CASE. In the year 1850, I was requested by a gentleman to visit a poor woman aged 42, the mother of six children, the youngest two years old. Since the birth of this child she dated her failing health.

For the last fourteen months she had been gradually losing flesh, with pains in the back, sickness, loss of appetite, perspirations, constipation, and slight cough. She had been treated for pulmonary disease by a private practitioner, and had undergone a digital uterine examination in a neighbouring infirmary. On examination with the speculum (May 8th), I found the uterus prolapsed, and the os imbedded in a mass of mucopurulent discharge (although the patient used daily alum injections), on the removal of which both labia of the os uteri were found extensively ulcerated some distance up the cervix. The patient was directed to have a liberal diet, and for medicine a vegetable tonic with iodide of potassium; for local application, the nitrate of silver. At the end of two months, finding my patient no better and the ulceration but little checked, I resolved to change my treatment both locally and generally. Having washed the parts ulcerated with a moist sponge, and freed the sore from all discharge, I painted the diseased portion with pure nitric acid, requesting the patient to keep the speculum (one of Fergusson's) fixed in its present condition for half an hour. The application caused no pain of importance. Internally, I gave twenty minims of the tincture of sesquichloride of iron twice a day, and left her for a fortnight. At the expiration of this period, I again applied the speculum, and was surprised at the improvement that had taken place. The excavated portions of the ulcer were quite filled up, and the whole disease presented a most healthy appearance. The same treatment was persisted in, and the nitric acid was again painted over the unhealed portion of the ulcer. From this time the symptoms gradually improved; the discharge of mucopurulent matter decreased; and, in less than two months from the time when the nitric acid was first applied, the patient's health was quite restored.

In the year 1853, I attended her in labour of her seventh child. There was not a single symptom of uterine mischief present; nor did there appear any cicatrix to interfere with the proper contraction and dilatation of the os uteri. This patient died of consumption in 1858, without presenting another indication of uterine disease.

CASE II. In the year 1859, M. H., a poor woman, aged 33, sent for me one night, having been suddenly seized with a pain over the region of the heart and fainting. She was a washerwoman, and had been delivered of an illegitimate child three years before. She considered her disease to be of two years standing.

There was great emaciation; vomiting after meals; cough; loss of appetite; diarrhoea; fainting upon the slightest exertion or excitement; and every symptom of general cachexia. The catamenia were regular, but attended with pain and difficulty in micturition. Between the menstrual periods, the discharge was excessive, thick, and grumous. On examination with the speculum, the vagina appeared red and inflamed, and gave evidence of its disordered condition by frequent small discharges of blood. The os uteri, as in the former case, was encased by a layer of mucopurulent matter, on the removal of which the following state of disease presented itself. The labia of the os could not be defined; but the whole cervix appeared one mass of ulcerated disease (so far as a bivalve speculum could display), bleeding upon the slightest touch. The menstrual period being over, nitric acid was applied; the ulcerated parts being well covered with it, by means of a glass brush, as before. A pledget of wool was then introduced, fastened to a piece of silk, and passed up the vagina, so as to cover the diseased portion. This application was repeated three times in six weeks; and the last examination displayed a sound and healthy looking surface. The medical treatment was the same as in the last case—tonics, with a generous diet. The patient has remained quite well up to the present; the

catamenia being regular, and no discharge occurring in the interval. This patient had been twice in an infirmary within the last year, but had only been examined digitally; and lotions of zinc and lead had been injected.

CASE III. In April 1860, I saw in consultation M. H., of a consumptive family, the mother of three children, the youngest fourteen months old. She had been ill for twelve months, and confined to her bed during five. She was much emaciated; the countenance was pale; breathing short; pulse feeble. She had occasional attacks of hysteria with violent palpitation, accompanied with pulsation of the descending aorta sufficient to raise the bedclothes. The catamenia were regular; the bowels constipated. She had no pain over the region of the uterus, but occasionally a discharge of mucopurulent matter, accompanied with pain.

After a careful examination, no organic disease being discovered, I suggested an examination of the uterus with the speculum, which was complied with. After washing away the thick stratum of mucopurulent matter in which the os uteri was imbedded, I discovered a large excavated ulcer situated upon the posterior labia of the os, and extending up into the cervix. The ulcer was very extensive, and evidently of the sloughing variety. I applied a good layer of the pure nitric acid, retaining the speculum until every chance of the adjacent mucous membrane being touched was over; and, on its removal, I plugged the vagina with wool. A tonic with hydrocyanic acid was given internally, to allay the violent sickness which disturbed her during the day; and generous diet with port wine was ordered. Ten days from this date, I again applied the speculum, and found the ulcer nearly healed, and the general symptoms much improved. The nitric acid was again applied to the parts of the ulcer not already cicatrised, and the general treatment continued. The patient slowly recovered her strength; the ulcer became perfectly healed, without another application; the discharge became natural; and in the early part of 1862 she was again delivered of a fine child, without the slightest indication of uterine disease being present.

I will now give some cases of simple ulceration of the os and cervix uteri, with or without hypertrophy.

CASE IV. In the year 1855, a lady, aged 30, married, consulted me for relief from a disagreeable taste in the mouth, sickness after taking food, lumbar pain, accompanied by severe constipation. She had never borne children, but had miscarried twice, and considered she was now three months advanced in the family way. I prescribed rest and the remedies usual in such cases, but without success; for she aborted the following week. In about six weeks after this event, when my patient had quite recovered, I requested to be allowed an examination with the speculum, which was granted. Upon examination, there appeared a slight amount of hypertrophy, for both labia of the os were elevated; but the fissure, quite into the cavity, was ulcerated and slightly excavated, looking as if small pieces had been cut out, discharging a fluid, not mucopuriform, as in the former cases, but such as would be expected from an ulcer on any other portion of the body. The whole of the diseased surface was fully displayed by a Ferguson's speculum; therefore, without removing the instrument, I freely painted the diseased portions with nitric acid with a glass brush, as before, allowing the liquid to pass into the cavity; requesting the patient to retain the speculum *in statu quo* for half an hour—this being the most effectual method of preventing the acid from injuring the adjacent parts. I next prescribed for her twenty drops of the syrup of the iodide of iron and manganese twice a day, and a liberal diet. I found it necessary to apply the acid to the surface ulcerated in about ten days, after which period, with the exception of slight hypertrophy, the part was quite healed, and the patient paid her

usual annual visit to the sea. I have since attended her in two accouchements; and the mother and both children are alive and well.

CASE V. C. S., aged 27, married, consulted me in 1856. When single, she had suffered from dysmenorrhœa, and between the menstrual periods from a discharge of a grumous character. Since her marriage, she had miscarried twice—once at six months, and the other time at the fourth month. She had all the appearance of being *enceinte*. The papillæ on the breasts were formed. I supposed her to be about four months advanced. I recommended rest; but in a few days afterwards I received a letter to say she had miscarried, and was going on well. Six weeks after this event, I requested an examination with the speculum, which was granted. The os uteri appeared swollen; but, on close inspection, the orifice between the labia presented an ulcerated appearance, with little indurations on its surface. The nitric acid was allowed to touch the whole of this surface; and this operation was repeated before the next menstrual period. The tincture of the sesquichloride of iron was given internally, and liberal diet and moderate exercise in the open air were recommended. Her recovery was rapid. I have since delivered her of two children—one in 1858, the other in 1860. The old symptoms have not shown any tendency to return.

CASE VI. In the year 1858, I visited Mrs. B., aged 26, married, the mother of one child. She had suffered since her confinement from dyspepsia, with pains in the back, occasional sickness, palpitations, and extreme nervous irritability. She had taken tonics, and had also consulted a London practitioner, who had applied the nitrate of silver, with temporary advantage.

On examination with the speculum, the os uteri externally appeared much hypertrophied; but the whole of the internal surface of the labia was much excoriated, exuding a muco puriform discharge. The nitric acid was applied as on the former occasion, being allowed to pass into the neck as far as possible. The tonic treatment was continued; and, one month afterwards, not the slightest unevenness or ulcerated surface remained. The hypertrophy continued for some time, causing painful defæcation; but, with the aid of sea air and bathing, it ultimately disappeared.

REMARKS. If, in the language of Dr. R. Lee, the women of England have suffered from the injudicious use of the speculum matricis, I think it is our duty to occasionally record cases containing proofs of the benefit resulting from its judicious employment. I am quite aware there are men even in the present day, well versed in uterine pathology, who believe and freely assert that for all practical purposes, digital examination is sufficient to explore all the ordinary affections of the os and cervix uteri. The gentleman quoted above says, "I am fully satisfied that the speculum does not enable us to decide earlier than the finger that cancer has commenced; and if it did so, as some maintain, and enable us to make applications to the os uteri, which could not be made without, not the slightest advantage would be gained in practice."

With regard to the first part of this statement, I have no wish to dispute the powers which some persons possess, from extensive experience, of ascertaining or obtaining a knowledge of diseases by the organ of touch; but as to the latter part, viz., the inutility of appropriate applications in the ulcerative stage of uterine diseases, including malignant, I wholly differ. Hundreds of females have testified to the comfort and freedom from pain experienced from the use of judicious applications to disease of the uterus, even in its worst stage—the process of ulceration. What, for instance, would have been the fate of Case No. II, where the poor woman had for months undergone digital examination, and consumed gallons of injection of lead and alum; and where, though

reduced to a shadow and despairing of ever receiving relief, after the loss of the greater part of the os and cervix uteri by ulceration, she recovers strength and is restored to her original health and vigour, and at the present time pursuing the most arduous of female occupations?

There is one remark emanating from the pen of Dr. R. Lee, viz., the impropriety of using the speculum to the virgin uterus, with which I quite coincide. For my own part, I never make use of it in the unmarried; and there is a certain class of cases of young females, with fair hair and light complexions, of the strumous diathesis, who suffer much from dysmenorrhœa when single, become much worse after marriage, and frequently miscarry. Upon examination with the speculum, ulceration, with or without hypertrophy, will, in almost every instance, be found the cause of mischief; and, in a mild degree, was no doubt the cause of the dysmenorrhœa prior to marriage. It is a question in my mind which would be the most correct course of practice; to cure this malady prior to marriage, and thus save the patient much suffering mentally and bodily, or to wait until the mischief has taken place, before the remedy is applied.

The subject under discussion, not being one treating of the diagnosis or exploration of uterine mischief, but relating to the properties of the various applications now in use for the amelioration or cure of that stage of inflammation of the most accessible portion, called ulceration, I will, in describing these applications, divide them into two classes; viz., solid and fluid. The first, or solid, are the lunar caustic; potassa fusa; the actual cautery; and lastly, Mr. Ellis's electric cautery. The second class, or fluid applications, are, injections of various substances, such as solutions of lead, alum, oak bark infusion, nitrate of silver, and various other substances, according to the nature of the case; and for escharotics we have chloride of antimony, tincture of the sesquichloride of iron, the acid nitrate of mercury, and the various mineral acids.

Before dilating upon the merits of these various applications, we must first see what we require them to do for the diseased parts, in order to bring about the object desired; and to do this correctly, I cannot do better than quote a remark of Dr. Bennet on the subject. "The only treatment to be depended upon, is one of such stimulation of the ulcerated part as to modify its vitality in such a manner as to induce a healthy action, and finally cicatrization." Taking this as our text, and the above named substances as our pharmacopœia, we must next consider upon which to pin our faith.

The first amongst the solids, the nitrate of silver, has been for years past the favourite in general practice, and has in many instances succeeded; but it is very uncertain and requires constant repetition, very much to the annoyance of the patient and to the dissatisfaction of the surgeon. The result arrived at, from extensive practice private and public, is that it is only palliative, and I am convinced that if the opinion of the majority of the profession who have used the remedy were taken, they would coincide with my verdict.

The second on the list, potassa fusa, may be associated with the actual cautery, from neither of which I have seen much benefit derived, but often great constitutional irritation. With regard to the electric-cautery, all I can say is, that women have already a great repugnance to the use of the speculum, and in all probability the addition of an electric-battery in that delicate region would cause a sensation of still greater disgust. The fluids, I think, give us more hope for success; considering, that to cure effectually an ulceration of any magnitude, the application must not only be made to the ulcerated surface, but must dip into the cavity itself.

The first on this list—injections—may be passed over, as requiring but few remarks. Their use is vaginal only; for, in nineteen cases out of twenty, they never reach

the os uteri; therefore, except in cases of leucorrhœa, or cancer, as cleansers of the vagina, or to convey some temporary relief in the form of an opiate, they are useless.

The next remedy to that which I am about to extol, is the acid nitrate of mercury, an application highly spoken of by Dr. Bennet. I believe that it possesses great stimulant and healing properties; but, from my experience of its use, it is not equal to the pure nitric acid. What the former accomplishes in two or three applications, the latter will perform in one.

My attention was directed to the powerful escharotic and healing powers of nitric acid some years past, in a case of deep-seated syphilitic ulceration of the perineum, when every other remedy had failed. It not only destroyed the diseased membrane, but at the same time produced a healthy action in the new tissues—a change so rapidly accomplished that both patient and surgeon were singularly surprised by the sudden metamorphose. Of all the membranes in the body the mucous seems to be the most adapted for this remedy, as shewn by the extraordinary power which it possesses of stimulating and producing a healthy action when applied to the ulcerated mucous membrane in cases of internal piles. Very little irritation is produced by its application.

In cases of cancer of the uterus when the stage of ulceration has commenced, and hæmorrhage made its appearance, nitric acid will be found the safest and most styptic application in arresting its progress. The tincture of sesquichloride of iron will not be found sufficiently powerful in such cases as an external application; but, as an internal remedy, it performs its office more effectually.

In conclusion, after reviewing the few cases here recorded, and again adverting to my text—"Stimulation to produce a healthy action, finally cicatrization"—I may with safety say, there are three things necessary for the cure (not palliation) of ulceration of the os and cervix uteri; first, a full view of the diseased surface; secondly, supporting the general health; thirdly, the application of an appropriate powerful escharotic, that will not only touch the external portion of the os uteri, but will dip full into its cavity; the practitioner, armed with the tincture of sesquichloride of iron as an internal and the pure nitric acid as an external remedy, need never despair of not fulfilling these intentions.

I am quite aware that the plan adopted by me in the cases recorded is not novel, but employed freely by other practitioners; but, considering that confirmation of treatment is the essence—the principle—upon which the profession wish to rely, my cases are designed to confirm the nitric acid treatment in cases of ulceration of the os and cervix uteri; and with this view I am inclined to give my experience of the great value of the agent.

---

**TESTIMONIAL.** A tea-service has been presented to Mr. C. Parsons, by the nurses and patients of the North Staffordshire Infirmary, as a mark of the kindness which they received at his hands whilst House Surgeon of the Infirmary.

**THE KING OF THE BELGIANS.** Professor Langenbeck's first visit to the King of the Belgians resulted in the greatest success. The stone was almost entirely removed. King Leopold, however, has thought it prudent to request the professor to defer his second visit for some time, as His Majesty fears his strength will be unequal to so speedy a repetition of the operation. Professor Langenbeck speaks with surprise of the clearness of mind and self-command displayed by the old king, who did not permit so painful an operation to prevent him from discharging his usual business. The distinguished surgeon received 200 Friedrich d'Or (£170) as *honorarium* for his services.

# British Medical Journal.

SATURDAY, FEBRUARY 14TH, 1863.

## THE LATE INQUEST AT LEAMINGTON.

[We have more than once called attention to the case of Dr. Philbrick, against whom an action has been commenced, in consequence of a most (in our opinion) unjust verdict given by a coroner's jury at Leamington. The case is one, in many respects, of much interest; and, as it has been through the evidence given by members of our profession—through medical evidence—that Dr. Philbrick has been thus placed in the position of defendant, we have placed the facts in the hands of an authority on the subject of midwifery, and have received from him the following deliberate opinion on the case. This opinion will, we are sure, satisfy our readers that Dr. Philbrick deserves the warmest sympathy at the hands of the profession; and we cannot doubt that, if he be eventually driven into a court of law, the profession will not hesitate in giving him the practical proof of their sympathy.\*]

The circumstances of the case which has recently occurred at Leamington, and in which the inquisition held by the coroner for the purpose of determining the cause of the death of Mrs. Bull, are such as to call for serious consideration on the part of those interested in the obstetric department of medical practice. The verdict of the jury, as it stands, is such as to throw blame on the practitioner who attended the case. The medical evidence, as to facts and as to points of medical practice, submitted to the jury, was such that the jury had hardly any alternative but to come to the conclusion they did. Inasmuch, therefore, as the evidence in question supplied the data on which the jury arrived at a conclusion so damaging to Dr. Philbrick, it is very essential that these data should be rigorously scrutinised as regards their scientific value and accuracy.

The case is a mixed one, and several important questions are raised by its discussion. The points which it is chiefly important to discuss are:—

1. What is the proper treatment of a woman in labour with twins, one of which has been delivered?

2. Is it possible for the second child, which, three hours after the expulsion of the first, is found to present footling, to undergo such change in position as shall result in its presenting by the two hands eight hours later?

3. What was the cause of the hæmorrhage which, as is asserted, accelerated the patient's death a fortnight after the delivery?

4. Does the occurrence of profuse hæmorrhage, as after labour, predispose to softening of the brain and extravasation of blood on the surface of the brain?

1. What is the proper treatment of a woman in labour with twins, one of which has been delivered?

In the text-books on Midwifery, it is really left to the discretion of the attendant either to expedite the delivery of the second child, or to wait the occurrence of labour-pains—that is to say, if nothing untoward have occurred or appears likely to occur. "Should the second child", says Denman, "present with the breech or inferior extremities, there can be no solicitude about the case. We must act as was before advised in such cases; that is, we must wait for the expulsion of the child by the natural efforts, if they be excited, or be equal to the effect; otherwise we must give assistance." . . . "The most fortunate presentation of the second child in a twin case is certainly with the inferior extremities." Dr. Ramsbotham says that "the length of time it would be desirable to wait after the birth of the first child before means are taken to extract the second, no dangerous symptom appearing in the interval, is a point admitting of some dispute, and deserving of very grave consideration." This author then goes on to observe that some practitioners decry artificial assistance merely in consequence of lapse of time; and "that often many hours, sometimes many days, have been allowed to pass after the birth of one child, before the labour was terminated." He agrees with Denman in thinking that, if uterine action is not re-established, some limit should be placed to our passive treatment. He specifies four hours—the time mentioned by Denman—"as perhaps the least objectionable." In a note it is mentioned that Collins' limit is two hours. If we turn to Rigby, we find it is stated in reference to the actual history of twin labours, that the uterus may resume its expulsive efforts in "twenty minutes after the birth of the first child, or it may remain quiescent for several hours without at all disturbing the regular and natural course of the process."

It is unnecessary to adduce further written authority on this point. There can be no doubt that, in the absence of dangerous symptoms, or of such malposition of the second child as to prevent delivery naturally, it is perfectly justifiable to wait the access of labour-pains before accelerating the delivery of the second child. It is a matter of opinion whether, under such circumstances, steps should be taken to complete the labour at once, or whether the case should be left to nature. This is not the place to argue which of the two methods is absolutely the best. It is sufficient to point out what is, according to recognised authorities, "admissible" practice.

To apply this rule to the case of Mrs. Bull. At the time when Dr. Philbrick was called in, was any dangerous symptom present? Here a careful attention

\* Since these lines were written, we learn that a declaration of action, with damages laid at £500, has been entered against Dr. Philbrick, to be tried at Warwick in the March Assizes.

to the facts of the case is necessary. The midwife (whose evidence, by the way, is contradictory) states that, before Dr. Philbrick had been called in, there was much hæmorrhage; but it does not appear certain whether she sent for Dr. Philbrick in consequence of this hæmorrhage, or because she did not know what was really going on. Dr. Philbrick stated before the coroner, that at the time of his visit there was no hæmorrhage; and the facts in the history of the case from the date of his visit at 7 A.M. up to 3 P.M., as derived from the statements of the husband, of Dr. Horniblow (who saw her at 1 P.M.), and of others, leave scarcely a doubt as to the fact that, during the time in question, hæmorrhage was absent. Before Dr. Philbrick arrived, the hæmorrhage spoken of by the midwife, of the occurrence of which to any extent there are grave doubts, did not make the patient even faint; the midwife made no reply when asked by the coroner, at the inquest, whether there was faintness. Dr. Philbrick found the patient, three hours after the birth of the first child, weak, and administered brandy and water; but there is no evidence that her weakness at this time was more than might very well be accounted for irrespectively of the occurrence of hæmorrhage. Dr. Philbrick, it appears, left the patient, seeing nothing in her general condition calling for immediate interference; ordering remedies of a restorative character to be given from time to time, and directing the midwife to send for him in case she required his service further. From about half-past seven to half-past eleven, nothing further appears to have occurred; there is no evidence that any hæmorrhage was going on. The husband, who went to call Dr. Philbrick the second time at 11.30, says nothing of there having been more hæmorrhage; and, even supposing there had been hæmorrhage going on subsequent to Dr. Philbrick's visit at 7.30, the midwife is clearly responsible for allowing it to proceed without calling in Dr. Philbrick, as he had directed her to do. But, as before remarked, the evidence clearly points to the conclusion that, from 7 A.M. to 11.30 A.M., there was no hæmorrhage.

Dr. Horniblow, who saw her at 1 P.M., states in evidence that he was told, at the time of his visit, there was no hæmorrhage going on; and, although the patient was found by him at that time to be exhausted, there is nothing to indicate that it was a dangerous exhaustion. Dr. Horniblow states, in fact, that her condition at that time was not such as to render it unadvisable to wait till another medical man could be called in before proceeding to interfere.

So far, then, as hæmorrhage is concerned, it does not appear evident that during the time Dr. Philbrick was at all concerned with the case—viz., from 7 A.M. to about 11 A.M.—the patient was in a dangerous state from hæmorrhage. The question of

hæmorrhage will have to be considered again presently.

2. Next we come to a question on which the evidence adduced at the inquest appeared to the coroner and jury most conflicting; viz., the nature of the presentation at the time of Dr. Philbrick's visit. Dr. Philbrick states that the child presented footling. At 3 P.M. Mr. Fenn Clark states that the presentation was that of both hands. From the other medical evidence given at the inquest, the jury could only draw the conclusion that, if Mr. Clark was right, Dr. Philbrick must have been wrong; and, in their verdict, they find that "he was mistaken as to its being a foot-presentation". This point is most important; because, applying the rule above laid down, if the case were footling, it might be left to nature; if, on the other hand, it were an arm case, no such natural termination could be expected. Now there appears nothing absolutely impossible in the supposition that both observers were right; and in this way. First, it is well known that, when the uterus is lax and loose, changes do take place in the position of the fœtus; and a slight degree of change would be quite enough to bring about an apparent evolution of the fœtus. Thus, supposing the fœtus to lie transversely, the feet and arms hanging downwards towards or in the os uteri, it will be a matter of accident whether the feet or the hands are expelled into the vagina first; and there is nothing inconceivable in the hands assuming the forward position late in the day, while at an earlier period the feet may have been lowest, forming really the presenting part. It is very true that, when the feet are felt in the vagina, the expulsion of the child generally takes place with the breech foremost; but, unless the breech itself be actually engaged in the pelvic inlet, there appears no reason why such an occurrence as that suggested above should be impossible. It is well known that, in "cross" cases, there may be simultaneous presentation of hands and feet at the os uteri; and it is perfectly reasonable to conjecture that, in the above case, both feet and hands lay near the os. They being so placed, the alteration in presentation is explicable. Further, it appears from the evidence that, during the interval in question, certain manipulations, the precise nature of which does not appear, were performed by the midwife. These manipulations may very well have assisted in producing the malpresentation. In his summing up, the coroner says: "It is perfectly clear, in the first stages of the affair, he (Dr. Philbrick) made a most unfortunate mistake."

The foregoing argument tends, however, to disprove the coroner's assertion. Admitting, therefore, as we do, the accuracy of Dr. Philbrick's diagnosis, this removes the case altogether out of the exceptional class; and it was quite open to Dr.

Philbrick, if he so pleased, to wait and allow the labour to be completed by nature.

3. We next come to a very important question; viz.: What was the cause of the hæmorrhage which, as is asserted, accelerated the patient's death fourteen days after?

First, as to the facts. *When* did the hæmorrhage occur? Reasons have already been given for concluding that before Dr. Philbrick's visit, or during the time for which Dr. Philbrick is answerable, there had not been any considerable loss of blood, though throughout the inquiry the coroner seems to assume that the contrary was the fact. In his summing up, he says: "We must assume the principal amount of hæmorrhage had occurred between the birth of the first child and the time that Dr. Horniblow saw her" (1 P.M.). But the coroner and the jury, and indeed the medical witnesses, appear to have overlooked the important fact that the chief hæmorrhage occurred after the second child had been extracted, at 3 P.M., by Mr. Fenn Clark. The latter gentleman, in his evidence, says "the subsequent hæmorrhage was fearful, and continued two or three hours before it could be stopped"; and further, that he considered it necessary to remain with the patient until 7 P.M. The placenta was, as Mr. Clark adds, detained. Now, at the inquest, the subsequent "fearful hæmorrhage" appears to have had no attention paid to it; whereas to the first hæmorrhage, the occurrence of which to any marked extent is problematical, is given the credit of producing all the serious subsequent mischief.

So far for the facts as to hæmorrhage. We now come to the consideration of its cause. We have not far to go to find an explanation of this. The woman was weakly; she had had eight children; she was pregnant with twins. All these circumstances conspired to predispose to the occurrence of uterine hæmorrhage. The serious hæmorrhage which took place was subsequent to the delivery of the *second* child, and was due to detention of the placenta. It was due to the same cause which protracted the labour; viz., inertia or sluggishness of the uterus—a sluggishness which for a time baffled Mr. Clark's doubtless skilful attempts to overcome. But this hæmorrhage, controlled with such difficulty by Mr. Clark, would it have been less, had the patient been delivered earlier of the second child? By implication, the coroner and the jury seem to have concluded that it would have been less; but it would be exceedingly difficult to prove this. Nay, the opinion might very well be defended by those who are in favour of allowing nature to act unassisted, that it was the best practice to wait, and that by so waiting there would be less risk of the occurrence of *post partum* hæmorrhage.

4. With reference to the connection endeavoured to be made out between the hæmorrhagic loss the

patient had sustained and her death from red softening and extravasation of blood on the brain seventeen days after the labour, that connection appears utterly devoid of foundation. The pathological doctrines adduced in support of this view are open to very serious question as to their truth; it is very certain they are not so generally accepted by the profession as to be capable of being made the groundwork of a charge, by implication if not literally, amounting to one of manslaughter. And it is unnecessary to consider this question at all, so far as this case is concerned, because if Dr. Philbrick was not answerable for the hæmorrhage, he could not have been answerable for the effects of the hæmorrhage.

There is one other point to which it is necessary to advert; viz., the position of Dr. Philbrick in reference to the patient and the midwife. Dr. Philbrick was called in by the midwife—so far as can be seen—to inform her as to what was going on, and it is not evident that he was called in for any other reason. Dr. Philbrick attends, gives the necessary opinion, and believing the midwife competent to conduct the case—a natural one, as he concludes—to a successful termination, ceases his personal supervision of the case.

There seems to be no reason for the statement that, under the circumstances, Dr. Philbrick was necessarily called upon to continue his personal attendance on the patient, seeing that a competent (reputedly so, at all events) individual was in charge. It will be very difficult, indeed, to prove that the patient actually suffered from, or that the subsequent accidents were in any way connected with, Dr. Philbrick's ceasing to give his continued personal attendance to the patient between the hours of 7.30 and 11.30 A.M.

It appears unnecessary here to discuss the question as to whether it was incumbent on Dr. Philbrick to undertake the management of the case anew at 11.30 A.M. when sent for, this question being one which cannot be determined by any amount of scientific reasoning. If the case be considered as one of consultation, which it undoubtedly was, the fact of Dr. Philbrick having attended once does not seem to imply any obligation on him to attend twice.

## THE WEEK.

THE London College of Physicians has issued its annual list. No Fellows have been added to the list during the past year. A little breathing time was required, we suppose, on the year following the famous one "of grace." During 1862, fourteen new Members have been elected, and sixty-three Licentiates. Naturally enough the number of Licentiates elected is less in 1862 than in 1861, when the election of Licentiates first came into operation.

SIR G. GREY has willingly accepted Dr. Brady's proposal of introducing a bill into Parliament for the regulation of the conveyance of persons, subjects of infectious diseases, in public conveyances. A great deal of nonsense has been talked upon this subject. It is evident that there is only one possible way of preventing the use of public conveyances by persons suffering from infectious disease, and that is by supplying the public with other means of conveyance expressly adapted for the occasion. It has been said by a large authority that a cabman is justified in refusing to take cases of this kind into his cab; but what does such an idea involve? Why it actually converts the cabman into a pathologist. A cabman is to decide whether or not his fare is the subject of infectious disease! So that if a man with an unfortunate rosy-spotted face should present himself, the cabman, relying on his own diagnostic powers, would have the privilege of saying—No! I shan't take you; you've got the small-pox! As we have said, the only way to meet the evil is to establish public conveyances for the purpose required. And, even then, it is very certain that the evil will only be met half way. Nothing that we can do can prevent the use of cabs and public conveyances by infected persons. The subjects of these infectious diseases are of course smitten by them before they are conscious of the fact; and when they recover from them they may still, in many instances, for a shorter or longer season, hand the disease on to others. All that legislature can do is to provide a partial remedy for the evil; and that much it is bound to do; but when such conveyances are established, it is not reasonable to suppose that any person, other than hospital and workhouse patients, will make use of them. If Dr. Brady meets all the difficulties of the case, he will show himself to be a most clever bill-maker.

It is with great pleasure we recognise the following candid remarks on a case which one of our weekly contemporaries (we might rather say two, for Tar-tuffe's friend, of course, follows suit in such a business) have attempted to convert into a scandal. The *Medical Times and Gazette* says:—"We do not think it fair or honourable to drag a respectable physician before his brethren because he has been entrapped into consultation with such a person (a homœopath)." The italics are ours.

WE are glad to find that what we lately referred to in the JOURNAL as a thing to be desired is about to be carried into effect by the London College of Physicians; viz., the electing of two Examiners in Surgery, instead of one Examiner. Two Examiners are required to give that seriousness and importance to the examination which the College evidently attach to it.

MR. COULSON has been elected to serve the office of sheriff for the county of Cornwall during the present year.

SIR R. PEEL is determined to do justice, and something more than justice, to Ireland. Led away by his newly acquired Hibernian enthusiasm, he gives the House of Commons the following piece of information, which, we are satisfied, will astonish our Irish medical brethren as much as their English confrères. It is curious that so knowing a hand as is Sir Robert Peel should have forgotten the odiousness of comparisons. "These dispensary medical officers", he says, "are superior to the village doctors in England; many of them have professional connexions extending over large tracts of country, and I believe they will be able to furnish most valuable returns."

THE following extract from an Indian journal, the *Friend of India*, gives us an idea of the complete and cruel fix in which the Indian medical officers have been placed by the government as regards their pay. It is a gross grievance that in the private councils of the Government the medical officers have no voice to represent their interests.

"We receive repeated and earnest inquiries on the subject of the amalgamation of the medical services and the publication of the Staff Pay Code. As to the former, we believe the Government of India are quite as ignorant as the public. From mail to mail a decision is expected; but as yet not the slightest indication has reached Calcutta from England as to what scheme of medical amalgamation the home authorities propose to adopt, nor when the question will be settled. This much only is as certain as anything about which Sir C. Wood and the Horse Guards are disputing can be, that the scheme adopted will not, in its main outlines, be Colonel Balfour's. Meanwhile the suspense in which Indian surgeons are kept, and the continued denial to both services of the substantial benefits of the Royal Warrant, are as disgraceful to the English authorities as the delay in paying the Indian prize-money. Were Parliament sitting, a few well put questions might secure justice."

It is reported that the two dental societies of London, the Odontological and the College of Dentists, are about to amalgamate. We should be very glad if other societies would follow their example. This union of forces is a much wiser proceeding than that of attempting to establish an Anthropological Society in the teeth of existing Geographical and Ethnological Societies.

VIRCHOW maintains, or rather is earning, a high position as a statesman. What will become of his scientific tendencies? The journals say:—

"Deputy Virchow followed, and spoke at considerable length. 'The Minister-President,' he said, 'tells us that the State must live, and from that proposition he starts to draw false inferences. I ask if that be a maxim for a statesman? Is it possible to say to a representative assembly, which has to grant money—The State wants

money, consequently you must give money; consequently you must assent to everything?" He referred to the addresses to the King sent up by the Absolutist party during the recess; and, amid the laughter of the House, read one of them couched in terms of ridiculous exaggeration. He indulged his sarcastic vein at the expense of the Premier, and apparently not without effect, eliciting from him a brief but bitter reply.

THE Commissioners in Lunacy have addressed a circular to all the superintendents and proprietors of public and private lunatic asylums, inclosing a copy of the following letter sent by them to Mr. Elliott of Munster House.

"Office of Commissioners in Lunacy, 19, Whitehall Place,  
January 9th, 1863.

"SIR,—In the letter addressed to you by the solicitors of the Board in the month of August last, the censure of the Board was conveyed to you for your culpable neglect, before taking charge of Mr. James Hall as an insane patient, to ascertain by reading the certificates that they were in all respects conformable to the statute; and the opinion of the Board was expressed in the following terms:—"There is no part of the duty of the proprietor of a licensed house which requires greater care than the examination of certificates. Your long experience ought to have rendered you familiar with the particulars in regard to them, which demand special attention; and the Commissioners, therefore, consider your negligence on this occasion as a most grave offence." Had you performed this, your obvious duty, you would not have received Mr. Hall, inasmuch as Mr. Guy's certificate was, upon the face of it, invalid and incapable of amendment under the statute, being founded upon an examination of the patient more than six weeks before its date.

"The question of the sufficiency of the facts set forth in medical certificates admits in many cases of much doubt; and the certificates, in this respect, may be amended after the reception of the patient. It is entirely different if the examination of the patient took place, as in the case under consideration, more than seven days prior to admission. Mr. Guy's certificate bore date six weeks subsequent to the day on which he last saw Mr. Hall. This was fatal to the validity of his certificate; and it is, therefore, of paramount importance that proprietors and superintendents of asylums should, before taking charge of a patient, carefully peruse every certificate.

"The Commissioners feel themselves called upon, in the existing circumstances, and for the above reasons, to intimate to you their determination to visit any violation of the provision of the law, such as that of which you were guilty in Mr. Hall's case, with the penalties of the statute.

"In order to the promulgation of their views, the Commissioners intend to circulate general copies of the present communication.

"I am, sir, your obedient servant,  
(Signed) W. C. SPRING RICE, *Secretary*.

"C. A. Elliott, Esq., Munster House, Fulham"

WE have received a long letter from Dr. Coombs of Bedford. He says, "I have now to assert that Dr. Burrows was perfectly right in assuming, as he did, that I was practising medicine according to his teaching"; and he then goes on to state that he had met "Dr. Evans, and that nearly all the practitioners of Bedford were in the habit either of meeting me in consultation or of interchanging professional services." He also points out instances in which he bleeds, gives croton oil, and in fact prac-

tises medicine. But one thing in this long letter he does not do. He does not say in two words that he does not practise homœopathy; although his letter, from beginning to end, would lead the reader to suppose that he had nothing to do with it, just as his practice led Dr. Burrows to suppose. Let Dr. Coombs say that he has nothing in the future to do with homœopathy, and we will gladly record the fact.

THE Institute of Lille offers as the subject of its next year's prize the following questions:—"What are the accidents connected with prolonged abstinence from food, and how are they to be distinguished from those proper to disease? What are the disturbances excited in the body through the exaggerated employment of alterative, antiphlogistic, purgative, and vomitive medicines?"

To perpetuate the remembrance of the services rendered to medical science by Professor Matteucci, as Minister of Public Instruction at Turin, the professors of all the universities of the kingdom of Italy have raised a subscription in order to offer him a grand medal of honour. The portrait is surrounded with the words:—"To Charles Matteucci, 1862"; on the reverse, "For having established unity in study"; and on the border, "The co-professors of the Italian Universities."

Louis Napoleon allows no opportunity to escape of rewarding with decorations his men of science. Of the French members of the jury who dealt with surgical, etc., affairs at the late exhibition, the following have been rewarded:—M.M. Balard and Nélaton have been made Commanders of the Legion of Honour; M.M. Barral, Bella, Demarquay, and Wurtz have received the rank of officers; M. Mason, the publisher, is made Chevalier, and so also M. Lecorché. The makers of instruments, Chevalier fils, Luer, and Mathieu, have been entered Chevaliers likewise. What rewards have been bestowed upon the English medical jury and the English instrument makers we know not. We suppose that, according to the custom of the country, the former will have to be contented with a clear conscience, and the latter with a brisk and more extended sale of their goods.

The three surgical instrument makers of Paris who obtained prizes at the Exhibition have celebrated the event by giving *fêtes* to their workmen, which *fêtes* "during the last few days have produced a remarkable degree of animation in the latin quarter of the city."

The corps of Italian military medical men, which in 1858 did not amount to more than 155 individuals, now consists of 755.

Casper, the medico-legist, a few weeks ago performed his thousandth medico-legal autopsy.

## EXHIBITION JURORS' REPORT.

**Preserved Meats.** Very little improvement has been made in this branch of industry since the Exhibition of 1851, notwithstanding the importance of it, and the large increase of its trade. Most of the meat is overdone, and is loaded with fat, and in many cases the food had acquired a metallic flavour from the vessel in which it was preserved.

**Pickles.** Since the Exhibition of 1851 a very great improvement has been effected in this branch of manufacture. Public attention has been drawn to the fact, that most of the green pickles of English commerce were tinted, or rather mordanted, with copper, the metal having been put into the vinegar purposely, in the form of a salt, or else communicated to the pickles by boiling them in copper pans. Little by little, however, this practice has been discontinued, or rather diminished, until the proportion of copper in a bottle of pickles hardly reached the hundredth part of a grain. Manufacturers were anxious to exclude even this small proportion; but they were met with the difficulty that, when the pickles were prepared without a minute quantity of copper, they were very unsightly, and in many cases were wholly unsaleable. The pickles of France and Belgium, however, demonstrated the fact, that very bright colour might be communicated or retained without the admixture of a particle of copper; and very recently some of the manufacturers of this country have accomplished the object without the aid of this metal. The finest specimens of this class of goods were, beyond all doubt, those very recently produced by Messrs. Batty and Co., who use a colouring material from vegetables and green foliage.

**Confectionaries.** A glance at the confectionary will show how great has been the improvement of its manufacture. There has also been a large increase in the quantity produced. No longer ago than the year 1855, the total amount of confectionary made in this country did not exceed 8000 tons in the year, whereas at the present time the quantity is not less than 25,000 tons *per annum*. One house alone, as we are informed, is making about two and a-half tons of lozenges and comfits per day, besides about fifty tons of marmalade, and sixty of jams in the course of the year.

Looking at the kind of confectionary which was in common use in this country at the time of the first Exhibition of 1851, it is manifest that a great improvement has been effected in every stage of its manufacture; no longer are the poisonous compounds of lead, mercury, and copper employed as colouring ingredients; and rarely do we find that any notable proportion of starch or flour has been introduced into the composition.

## OUR LONDON HOSPITAL SICK.

*The Social Science Review* has the following calculations respecting the sick and medical attendants of London Hospitals:—

"From the year 1856 to 1861, the average number of persons treated in the large hospitals, amounted altogether in in-door and out-door relief to 380,262; since then certain of the hospitals have published an increase, others a slight decrease, in patients received and treated. In the same year the number of physicians and surgeons who treated these patients amounted to 150. Twelve of these at least were consulting physicians or surgeons, who held office nominally, and did no work. Lately, some eight or nine acting physicians or surgeons have been added to the collective staffs, and as many consultants have disappeared. We may, therefore, take fairly and honestly the state of the hospitals in question,

—and taking them as average specimens of hospital works and workers,—that 380,262 sick people are treated annually by 150 medical officers.

"We have calculated the labours of 150 medical men among 380,262 patients, on the idea of an equal division of work. But the work is not equally divided in fact, so that our calculation is not quite exact when compared with actual practice. Of the 150 men, 82 are what are called full physicians or surgeons; these attend to the in-patients. Technically, they are said 'to have the beds,' meaning the patients in the beds of course. The other physicians and surgeons, 68 in number, are called the assistant-physicians and surgeons; these see the out-patients, and they have not, except by courtesy of their colleagues, or by special provision, any beds. It is quite an event in a man's life, in fact, when he is allowed beds. The number of in-door patients falling to the 82 chief officers amount, out of the 380,262, to 30,316. The number of out-door patients, falling to the 68 assistants, amount to 349,946. The work consequently bears this division. Each full physician or surgeon has under hand 369 cases a year; which at the rate of 16 visits to each patient, gives to him 18 a day, for every day in the year, Sundays excluded; while each assistant has 5,146 cases, which, at the rate of 8 visits to each case, yield rather more than 131 cases a day for each day in the year, Sundays excepted, or nearly nine hours work a day at four minutes to each patient."

## THE HOTEL DIEU OF PARIS.

A DEMOLITION of the hospital of the Hôtel Dieu and its reconstruction, which the inhabitants of Paris have loudly called for during many years, are at length decided on. The place on which the new hospital is to be erected is not yet fixed; but a decision must shortly be adopted, inasmuch as the present building is so defective. This is the second time that the Hôtel Dieu will have been displaced. The primitive position of the Hôtel Dieu was to the south of the little church of St. Christophe, nearly in the middle of the *parvis* of Notre Dame. The Seine was not then as it is now, confined with walls, and its waters after the least flood washed the wall of the old city. During the excavations made in 1847 the foundation of this wall was discovered. It followed a line parallel to the river, and its position is distinctly indicated by the iron railing of the garden of the Hôtel Dieu in the Rue Neuve Notre Dame. The present building, consequently, could not have been erected until after the demolition of that wall. The opening of the Rue Notre Dame, which was accomplished in 1181, in order to facilitate the approach to the grand entrance to the church then being constructed, and which absorbed a portion of the church of St. Christophe, coincides with the destruction of the Gallo-Roman wall. Thus the appellation under which it was generally known—*Hospitale Pauperum quod est apud ecclesiam Sancti Christofori*—was beginning to be replaced by its present title, *Domus Parisiensis Dei*. The hospital, moreover, did not in those distant ages possess the character which it subsequently acquired. It was rather a house of refuge for mendicants and foreigners. The friars, according to the ancient custom, washed the traveller's feet. It was not until the reign of Philippe Auguste that invalids were admitted. The Prince, who may be called the founder of the hospital, built the Hall St. Denis and its additions. Blanche de Castille, his daughter-in-law, founded the Hall St. Thomas, and Louis IX built the large hall on the bank of the river and a chapel beside the Petit Pont. The crypt, which extends under the ground occupied by the old church and by the Hall St. Thomas, and which now serves as a wine-cellar, has preserved the character of the period,

and the distinct signs of the thirteenth century. Louis XI decorated the two doorways opening on the Petit Pont. All the buildings on the banks of the Seine were constructed during his reign. In 1535 Cardinal Duprat constructed a magnificent building called the Legate's Hall. It occupied the place now used as a clothes store. When Francis I heard of this munificent act of the Cardinal, he observed that the hall should be very large to contain all the people he had ruined. It appears from the bill of the carpenter who made the beds for this hall that a bench was placed beside each bed, called "the bench of repose"—that is, if the bed contained three invalids, it might be made to accommodate six by permitting three to sit on the bench while three took their turn in the bed. During an epidemic which prevailed in Paris eight persons were placed in a bed. The buildings of the Hôtel Dieu being in a dilapidated state during the reign of Henry IV, they were repaired by that Monarch. Between the years 1802 and 1804 the Hôtel Dieu was again repaired, and the building lost its mediæval character. The chapel, with its doorway, was taken down, and the architect, Clavereau, replaced the handsome and delicate work of the 13th century with a heavy peristyle.

### THE ARMY MEDICAL STAFF.

WHAT is it that has given rise to the present deeply-felt discontent among the medical officers of the army? What cause or causes are now in operation deterring young medical men from offering themselves as candidates for commissions in the service?

How comes it that the remedy which was effectual in allaying discontent in the commissariat, the ecclesiastical, the pay departments, has failed so signally to cure the medical officers of theirs? Is it that in the one case it has had fair play, while in the other it is believed not to have been honestly tried? We fear it is even so. The medical warrant purported to regulate the rank, pay, and promotion of medical officers. It was accorded by Government, after its necessity had been demonstrated, not merely as a matter of generous feeling towards a hard-working and self-sacrificing profession, but as a necessity, in obedience to the commercial principle of supply and demand. Young medical men of any mark refused to enter the military medical service in sufficient numbers at the then rate of pay and status. The army could not exist for a month without them. It is needless now to attempt to conceal what is notorious; the War Office had much difficulty in overcoming the strenuous opposition of the Horse Guards to that part of the warrant which gave increased relative rank to medical officers, without which it would have been inoperative. The Warrant was, however, published at last, and medical officers received it with the respect due to its declared royal origin, and thought that it formed the Magna Charta of their professional rights. They now complain that it has been transgressed in several ways, and we feel bound to give place to the complaints of such a body of men.

By the 17th clause of the Warrant, it was stated to be the Queen's pleasure that "such relative rank shall carry with it all precedence and advantages attaching to the ranks with which it corresponds." One exception only was made; it was specially said, as regards precedence of courts-martial, "where our Royal will and pleasure is, that the senior combatant officer be always President." Few medical officers knew that they were eligible to sit on courts-martial; none that we ever heard of claimed to do so; although within our knowledge, where purely combatant officers were not to be had in sufficient numbers, military surgeons have been called in to supply their place. We are quite sure that medical

officers are not desirous to serve on courts-martial, although we are disposed to say that where one of their own number is arraigned before such a tribunal, it would only be fair to have a proportion of medical officers in the court. Be this as it may, military surgeons have always been required to sit on boards relating to various matters not strictly military; it constantly happened that an old surgeon and a young lieutenant were on a board together. The young military officer did not affect to know anything of a matter, nine times out of ten, quite out of his professional ken, but he acted as president of the board, and controlled its proceedings. The surgeon had to sign his name to the proceedings after him. This was the practice stigmatised by Lord Dalhousie, when Governor-General of India, in language that we must recall to the minds of our readers:—"It is impossible to imagine what serious justification can be offered for a system which, in respect of external position, postpones service to inexperience, cunning to ignorance, age to youth; a system which gives a subaltern who is hardly free from his drill, precedence over his elder, who, perhaps, has served through every campaign for thirty years; a system which treats a member of a learned profession, a man of ability, skill, and experience, as inferior to a cornet of cavalry; a system, in fine, which thrusts down grey-headed veterans below beardless boys."

When the Warrant was issued it was thought on all hands that this system was at an end. Surgeons then very properly claimed to sit on boards above described in virtue of their relative rank, and of course, if the senior be not present, to sit as president. They were ordered to sit on boards as they had done before. This they hold to be a direct breach of Her Majesty's Warrant. Shortly afterwards the Commander-in-Chief directed that when a medical officer was likely to be a senior on a board, "he should be summoned as a witness," obviously that military officers might be spared the indignity of sitting on a board or court of inquiry with a "doctor" as president. This gave the second blow to the confidence of the service in their Magna Charta. By the 17th clause medical officers having the rank of Inspector-General claimed the forage allowance granted to the rank to which they were assimilated. It was refused, on the ground that if two horses were enough for a Deputy-Inspector-General, they were enough for the superior rank. Again, a regimental or staff surgeon ranking under the Warrant with a field officer is not allowed the baggage of that rank, a direct breach of the very letter of that document. The adjutant of an infantry regiment is allowed the privilege of a second batman for the care of his horse, so is a major, but the commanding officer may give or withhold it from the surgeon at his pleasure. Before the issuing of the Warrant a surgeon of a Dragoon Regiment was allowed to keep two horses; when promoted to the relative rank of field officer under the Warrant, he claimed the right of his rank, freely accorded to the major, of keeping four horses. It was refused. It may be that a surgeon does not require four horses,—neither does the major; the larger number is simply an appanage of rank, and as such is regarded, and under the new system the medical officer was justly entitled to the same privilege as the major. Lastly, the greatest grievance of all, and the one most felt and resented, was the taking away from surgeons the equal relative rank of major—that is, making them invariably junior of that rank. The surgeon is now, it is complained, in the face of the solemn promise of October, 1858, converted into something more than a captain and less than a major.

Into the many ways in which the Warrant is stated to be broken in its spirit, we have not space to enter; the above, it is held, is enough, and more than enough, to explain why the old chronic discontent again prevails in the service, and why young medical men, educated up to the high standard the new regulations require, have

again fallen below the demand. The warrant of 1858 was not an isolated measure. The aim and end of it was to secure for the service of the State the highest available professional talent and skill.

We have already quoted Lord Dalhousie's famous minute, and with one other extract from that dispatch, demanding equal justice for military surgeons, we conclude:—"I respectfully submit that such inequalities are founded on no sound grounds of justice, expediency, or policy; no valid reason has ever been given or can be alleged for maintaining them. Their effect is to depress the spirit of the medical officer, to depreciate a profession and class of service which ought to be held in the utmost respect, and supported equally from motives of prudence and gratitude." (*Army and Navy Gazette*.)

## SIR WILLIAM PETTY, THE FOUNDER OF THE LANSDOWNE FAMILY.

THE fortunes of the Lansdowne family were formed by a man chiefly known as the founder of a new science—the science of Political Arithmetic, but whose life involved so many of the modes of activity which a very remarkable period afforded, that one is surprised to find that it has been almost entirely overlooked by the biographers. Sir William Petty, the son of a clothier at Romsey, fought his way desperately to fame and fortune in the times of the Commonwealth and the Restoration. He entered the navy, and soon left it; he tried merchandise for a time, and left that also; he then invented a copying machine, but received no profit from it; he turned to medicine, and dissected in Paris under the guidance of Hobbes; he became Professor of Anatomy at Oxford; to anatomy he added music, and became professor of this art at Gresham College; subsequently he became physician to the Irish army during the Protectorate; not content with these occupations, he contracted for the admeasurement of lands in Ireland forfeited by the rebellion, his survey being still of great value in the law courts as a work of reference; he became a member of parliament under Oliver; he was knighted by Charles II; he was one of the founders of that Royal Society which has had so much influence on the development of science; he at length became a shipbuilder, inventing a double-bottomed vessel to sail against wind and tide; and, finally, by various important works on taxation and national wealth, he established, as we have said, the new science of Political Arithmetic. He died, leaving what in these times would be considered very large possessions—personal estate to the amount of £15,000, and landed property to the value of £6,500 a year. Such are the self-made men who supply our English aristocracy with new blood and preserve it in vital connection with the hearts of the people. He married a lady who was Baroness Shelburne in her own right, and by her daughter, his only surviving child, who had intermarried with the Kerry family, he became the great grandfather of the celebrated Earl of Shelburne, the first Marquis of Lansdowne, and the father of the deceased Marquis.

MIDDLESEX HOSPITAL. Among the legacies bequeathed during the past quarter to this charity, there was one from Mr. Cropper, who was ninety years old when he died, and had, it appears, survived all his relations. He was a barrister-at law, and lived in the most frugal manner in his chambers at Gray's-inn. The amount of his property at the time of his decease is estimated at about £4,000 *per annum*, and £10,000 in money, the whole of which he has bestowed upon London charities, selecting Middlesex Hospital as his residuary legatee.

## Association Intelligence.

### NOTICE REGARDING NEW MEMBERS.

By desire of the Committee of Council, the General Secretary requests that the Local Secretaries will be good enough to forward to him the names of all New Members who join the Association through the Branches; as otherwise the JOURNAL cannot be sent to them.

PHILIP H. WILLIAMS, M.D., *General Secretary*.

Worcester, November 10th, 1862.

### BRANCH MEETING TO BE HELD.

NAME OF BRANCH.	PLACE OF MEETING.	DATE.
BATH AND BRISTOL. [Ordinary.]	Athenæum, Corn Street, Bristol.	Thursday, Feb. 26, 7 P.M.

### EAST KENT DISTRICT MEDICAL MEETINGS.

THE next meeting will be held at the Pavilion Hotel, Folkestone, on Thursday, March 5th, at 3 P.M.

THOMAS BOYCOTT, M.D., *Hon. Sec.*

Canterbury, February 10th, 1863.

## Reports of Societies.

### ETHNOLOGICAL SOCIETY.

TUESDAY, FEB. 3RD, 1863.

J. CRAWFORD, Esq., President, in the Chair.

ON THE PSYCHOLOGICAL DIFFERENCES WHICH EXIST AMONGST THE TYPICAL RACES OF MAN.

BY ROBERT DUNN, F.R.C.S.

As papers of a psychological character have so rarely been read at the meetings of the Society, the author offered no apology for asking the attention of the meeting to this subject, being satisfied that if there was any branch of the science more interesting than another it was that which related to the psychological differences which characterise the different varieties of the human species. That the genus *Homo* was one, the author believed and maintained, on the ground that in man's moral and religious attributes the inferior animals do not participate; and it was this, he considered, that constituted the difference between him and them. The barrier was thus, he considered, impassable between man and the chimpanzee and gorilla; and wherever two-handed and two-footed man, in his erect attitude and with his articulate voice, is found, his claims to our common humanity must be immediately acknowledged, however debased the type may be or mean the garb in which that humanity is clothed. Mr. DUNN's conviction was, that there was proof of a general unity exhibited in all the races of the great family of man; inasmuch as they were all endowed with the same instinctive, sensational, perceptive, and intellectual faculties—the same mental activities, however much they may vary in degree. It had, he thought, been fairly argued that all the races of the human family form but one species, from the physiological fact that they are all capable of fruitful union, which would not be the case with the hybrids of two species of even the same genus. Believing the brain to be the material organ of the mind where the ultimate molecular changes take place, and whence the mandates of the will issue, the author considered the study of the cerebral organisation and development in the various typical races as one of the most effectual means of better understanding and elucidating the psychological differ-

ences which characterise them. This subject, however, was one that yet required to be worked out; and ethnic psychology was still a desideratum. The difficulties which formerly beset it no longer exist, and it was, he thought, to our shame that, notwithstanding our extensive and daily spreading intercourse with all the nations and races on the face of the earth so little had been done. The author then reviewed at length what had been done by anatomists and ethnologists, including Spurzheim, Tiedemann, Gratiolet, Herbert Spencer, Huxley, Owen, and others.

In conclusion, he pointed out that the lower savage races, such as the Sandwich Islanders, made progress in the early part of their education, and were so far as apt and quick as the children of civilised Europeans; but at this point they stopped, and seemed incapable of acquiring the higher branches. The Sandwich Islanders have excellent memories and learn by rote with wonderful rapidity, but will not exercise the thinking faculties. They receive simple ideas, but not complex ones. In like manner, it was found, practically, that negro children could not be educated with white children. In all these cases, as well as in the minor cases continually occurring amongst ourselves of inability to understand subjects and reasonings of a certain order of abstruseness, the true explanation is, that the cognate faculties have not reached a complexity equal to the complexity of the relations to be perceived; and, moreover, it is not only so with purely intellectual cognitions, but it is the same with *moral* cognitions. In the Australian language there are no words answering to justice, sin, guilt. Amongst many of the lower races of man, acts of generosity or mercy are utterly incomprehensible—that is to say, the more complex relations of human action in its social bearings are not cognisable. This, the author thought, was in accordance with what *a priori* might have been expected to have resulted from organic differences in the instruments of the higher psychical activities—or, in other words, in the nervous apparatus of perceptive and intellectual consciousness. The leading characters of the various races of mankind were simply representatives of particular stages in the development of the highest or Caucasian type. The Negro exhibits permanently, the imperfect brow, projecting lower jaw, and slender bent limbs of a Caucasian child some considerable time before the period of its birth. The aboriginal American represents the same child near birth; the Mongolian the same child newly born.

In the discussion, the president, Dr. Copland, Mr. Luke Burke, and Dr. Donovan, took part.

#### HARVEIAN SOCIETY OF LONDON.

ANNIVERSARY MEETING, JANUARY 15TH, 1863.

WEEDEN COOKE, Esq., President, in the Chair.

*Report.* The Honorary Secretary read the Report of the Council. It was proposed by Mr. HENRY THOMPSON and seconded by Dr. BALLARD,

“That the Report be received and adopted, and that the thanks of the Society be given to the officers and Council.”

The Treasurer laid before the meeting a statement of the expenditure and income of the Society for the past year, showing a balance in hand of £79:8.

*Officers and Council.* At the close of the ballot the following gentlemen were declared elected officers for the ensuing year. *President*: Henry W. Fuller, M.D.; *Vice-Presidents*: William Adams, Esq., J. B. Sanderson, M.D., W. Sedgwick, Esq., W. Wadham, M.D.; *Treasurer*: Henry William Fuller, M.D.; *Honorary Secretaries*: J. B. Curgenvin, Esq., C. R. Drysdale, M.D.; *Council*: P. Burke, Esq., F. Cock, M.D., T. K. Hornidge, M.B., E. Hart, Esq., T. H. Hill, Esq., J. C. Langmore, M.B., W. B. Mushet, M.B., W. O. Priestley, M.D., O. A. Field,

Esq., E. Shercombe, Esq., H. G. Times, Esq., J. B. Walker, Esq.

#### PRESIDENT'S ADDRESS.

The Annual Address was then delivered by Mr. WEEDEN COOKE, the president.

The President after thanking the Society for the support they had afforded him during his year of office, entered upon the inquiry, “What have we done, what are we doing, to advance our knowledge of disease, our means of alleviating, not only the ‘ills which flesh is heir to,’ but likewise those illegitimate offspring, which are bred of ignorance of the laws of nature and of uncurbed vice and passion?”

On reviewing the history of the Society since its foundation in 1832, it appeared that Dr. Marshall Hall, Dr. C. J. B. Williams, Dr. Hope, and Dr. A. T. Thompson, had been its early associates; and had developed the first germs of those grand views which made these names illustrious, in the meetings of this Society. So far back as 1835, Dr. Green had anticipated the present Turkish bath mania, and shown the advantages to be derived from the hot air and other baths, when directed by a practitioner skilled in the knowledge of the disease proposed to be brought under the influence of these remedies. Mesmerism had been fully, freely, and liberally discussed in the Society, and the decision arrived at when it was a fashionable belief was well supported by the subsequent decadence of the illusion.

The subcutaneous division of tendons for the cure of club-foot was ably brought before the Society in 1838, by Mr. B. Phillips. This was, perhaps, the first notice taken in our country of the labours of Stromeyer in this important branch of surgery; and, although Dr. Little, from his persevering energy in establishing the Orthopædic Hospital, and bringing the subject before the profession in the published works, has obtained the credit of naturalising orthopædy amongst us, Hunter had long before proved the advantages of subcutaneous incisions, and the great surgeon, whom we have recently seen pass full of honours nobly won from amongst us, proposed and executed a plan for the cure of varicose veins by subcutaneous section. This Society owes a debt of gratitude to its learned and most worthy member Mr. William Adams, for several instructive papers, illustrating the advances made in the pathology and treatment of these cases; and the marked absence of unsightly cripples from our streets notes the benevolent progress of our art.

In intimate alliance with this subject, come the great improvements made of late years in the treatment of diseases of joints. Almost every full-grown man can remember that “white swelling” was the general term for all diseases of the knee-joint, and that the limb or the life of the sufferer was surely condemned. Now, either by excision of the ends of the bones, or by the still more conservative plan so ably advocated by Mr. Hilton in his college lectures, diseased joints are restored to usefulness, and many lives are saved by abstinence from amputation. Mr. Cooke had been able to put this latter plan of treatment into operation in several cases of disease of the hip, knee, wrist, ankle, and other joints. He thought that thanks were due to Mr. Hilton, for his elucidation of those anatomical and physiological data upon which the whole rationale of this treatment securely rests, as well as for his able demonstration from experience of the results to be obtained from this practice.

The swing-cradle, and the starched apparatus, in securing comfort, and a rapid release from the recumbent position in fractures of the extremities, were worthy objects of admiration.

Ovarian disease, ruptured perinæum, and vesicovaginal fistulæ, were referred to in illustration of the progress of surgical art; whilst iridectomy, as well as other new operations in ophthalmic surgery, together with the introduction of the ophthalmoscope, elicited a

high eulogium upon the skill brought to bear upon this special branch of practice.

Dr. Marshall Hall's method of restoration in cases of asphyxia from drowning, if not complete in itself, at any rate gave the first impulse to a mode of inflating the lungs which cannot fail to be instrumental in saving the lives of hundreds of our fellow creatures. Epilepsy also was brought before the Society, by the same distinguished physician, on the 1st of May, 1856, being his very last visit previous to that retirement to Brighton, which was to be followed, too soon for science, by his lamented death from cancer of the œsophagus.

Diabetes, the subject of a discourse by Dr. Hodgkin in 1853, would seem happily to be giving way to the physiological and pathological inquiries and experiments made during the last ten years; and we have, in the researches of Dr. Pavy especially, well-grounded hopes of attaining considerable influence over even this intractable malady. The dissolution of stone in the bladder and kidney, the beneficent uses of chloroform, and many other subjects were cursorily alluded to, as having formed matter for discussion. In a paper read before the Society in 1860, the president had shown how readily urethritis yielded to treatment, when it was regarded as a simple local inflammation. He had also published opinions upon the subject of syphilis, which were contrary to the generally received doctrines. He looked upon the so-called secondary symptoms as nature's own method of eliminating an animal poison, which was artistically balked and hindered by the customary mercurial course. He related the case of a gentleman who took six courses of mercury with quantities of iodide of potassium and sarsaparilla, and was, after ten years treatment, a miserable cripple.

In no part of the history of our profession, from Hippocrates downwards, are we without records of attempts to check the ravages of cancer. As we may think now, many of these attempts were fruitless, and only deserved the failures they experienced; but they were done in accordance with that Aristotelian method of reasoning which prevailed before the inductive theory of Bacon had wormed its way into the schools of science. Now that we reason from facts, and prefer to confess ignorance, rather than puzzle our brains to invent theories which will probably turn out to be "as idle as the wanton summer wind," it seemed highly probable that from the combined uses of physiology and pathology, and not entirely ignoring experimental therapeutics, a considerable control may be obtained over the disease. It is believed that from those minute vessels which connect the arterial and venous systems—the capillaries—a fluid, by the wonderful power of exosmosis, is poured into the intercellular substance; and that it there forms material for the construction and regeneration of the tissues of the ever-changing body. This process is as quiet and natural and universal as the laws which govern the planetary system; but as in the skies there are comets, so in man's structure we have eccentric phenomena, which go far to baffle our philosophy. With or without an exciting cause apparent to our senses, the constructive material poured out of the capillaries shall, in some part of our bodies, be composed of cells which have not the usual formation. Instead of being globular or fusiform, they shall assume strange shapes, and the nuclei shall be unusually multiplied. These are the microscopic evidences of that disease which we designate by the quaint term of cancer; and, if we take them in connexion with the knowledge that, in a certain proportion of cases, there is an hereditary tendency; that blows have so small an influence in the supposed production of the malady, that but one person in eight, in a collection of nearly three thousand cases recorded at the Cancer Hospital, was enabled to trace the commencement of the disease to that cause; and that operation is but a temporary expedient in putting off the fatal issue; that

the disease will surely return in the cicatrix itself, or in some neighbouring or remote part of the body, at a period varying from six weeks to ten years,—we shall find it difficult, if not impossible, to agree with those surgeons who still maintain that cancer is a local disease—that a part only, and not the whole system, is at fault. Although operation in cancer must be abandoned as a means of cure, it is nevertheless, in selected cases, acceptable as a compromise; and unfortunately, in this sublunary world, we are obliged to make compromises and build halfway houses in many paths of life.

Five-sixths of the cases of cancer that come before us are in the female sex; and of these, three-fourths are made up entirely of scirrhus of the mamma. It is, therefore, of the first importance that we should arrive at the best mode of treating this particular lesion. There are different temperaments to be observed, various degrees of health to be noted, the assurance of mental and bodily comfort to be obtained, before any plan of treatment can be decided upon with advantage to the patient. If statistics could decide the question, operation, whether by knife or caustic, would give us but poor comfort. Of 307 cases of operation noted at the Cancer Hospital, the average lapse of time before the disease returned was but eleven months.

It is generally conceded amongst histologists that the cancer-cell is comparable with the cell-formations of embryonic existence; that it is, in fact, deficient in a something which, if added, would make it form healthy adult tissue. It is patent that this "something" must come from within, and that the blood must be the means of supplying it. If we cannot pour into the body nutriment to manufacture the very highest health in the vascular system, so that no more half-fledged cells shall be created, we shall necessarily fail in checking the fatality of this malady. The means to that end it were a work of supererogation to indicate in a society of highly educated practitioners.

In the epithelial form of the disease, perhaps, we have more favourable results from operation, provided there be no extension of the disease to the neighbouring glands. The lower lip is the most frequent seat of epithelial cancer; and appearing, as it does, so commonly in men and rarely in women, it cannot be doubted that the pipe or the cigar has something to do with its development; although why the lower lip should almost invariably be selected in preference to the upper does not very clearly appear. It is only by carefully selecting the cases for operation that any good can be effected in this manner. Should there be any thickened cord extending from the indurated lip, or any glandular enlargement beneath the maxilla, or at the angle of the jaw, it is worse than useless to operate; for the disease will assuredly return in a more aggravated form. Epithelial cancer of the tongue is never benefited by operation; but there are many ulcers of the tongue mistaken for cancer, which will readily yield to well-adjusted treatment.

After referring to epithelial cancer of the extremities, and to the inefficiency of all treatment in medullary cancer, the President continued: I have sketched but a few of our battles won, of our peaceful victories over disease; and I have indicated where we have still ramparts to storm, almost forlorn hopes to encounter. The men of the past in this society have laboured like good soldiers in the cause; the men of the present, with improved machinery for the examination of the eye, the ear, and the larynx, cannot fail to subjugate many of the ills which have hitherto eluded our attacks, whilst there are still grand deeds of valour open to the laborious student who is just entering upon this wide field of enterprise. Thus, our glorious contest with disease goes bravely on,

"Requented from labouring sire to son,  
Though baffled oft, is ever won."

## Correspondence.

### HEALTH ASSURANCE OFFICES.

LETTER FROM J. M. BRYAN, M.D., F.R.C.S.

SIR,—My attention has been arrested by a communication in a contemporary journal on the above subject, in which I fully coincide. To the question asked, as to the existence of any provident society for medical men during sickness or disability, I named the Norwich Provident Insurance Society, established in 1860, in which insurance can be effected against sickness, etc.; although I do not know much of its working.

I have (in common with the correspondent I noticed) long felt the urgent necessity of some institution in which members, by paying an annual subscription of from two to ten pounds, might be entitled to relief during sickness, disability, or old age, to the amount of two pounds weekly, or more, if so determined.

Having myself, three years since, passed through the ordeal of a fearful illness, confining me to my bed for twelve weeks, and subsequently disabling me for nearly twelve months from attending to my practice, which I had conducted single-handed for nearly thirty years; and also constantly having cases brought under my notice of medical men disabled, or their wives and families left destitute; no one can better judge of the absolute and urgent necessity of some provident society other than those already in existence. I have often longed to join one on the principles of the Clergy Mutual, from which a poor curate, by paying a yearly subscription, draws, in case of illness, two pounds per week.

I think that, with our worthy founder as treasurer and the present Honorary Secretaries for a staff, the thing might at once be done; and then the question would not so often be asked, what good does the British Medical Association? by many lukewarm members.

I should be glad to cooperate with any one medical man or number of medical men for the purpose of at once forming such an institution. I think that the question only requires agitation and publicity for its establishment; and that our Association, with its benevolent founder at its head, might soon form a society.

At a recent meeting of our South Midland Branch, I brought before the members the question of endeavouring to join the Society for the Relief of Widows and Orphans of Medical Men in London and its Vicinity; but I have received an answer from its secretary "that no members can be received out of its present bounds." Hoping that this may be the means of agitating, and thereby establishing an association, for the furtherance of which I shall be happy to receive communications and exert myself, I am, etc.,

JOHN M. BRYAN,

*Hon. Sec. and Treasurer to the South Midland Branch of British Medical Association.*

Northampton, February 7th, 1863.

SIR,—Can you inform me if there is any society connected with the medical profession to which a medical man can subscribe, with a view to receiving a certain amount if incapacitated by sickness? or from which he can derive aid if permanently hindered from following his professional duties by age or physical infirmity?

It seems to me that the mechanic who pays into a good club is better off than the professional man in case of illness; and I cannot help thinking that many of my professional brothers would gladly avail themselves of the opportunity of prudently setting by a little against a winter day. Societies of this kind may exist, but I am ignorant of their whereabouts; and it would be a comfort to me if I could insure in the way I

mention, without feeling that I might be assisted by some *charitable* medical body, but had a *right* to the aid I required.

I am, etc.,

ENQUIRER.

[Our correspondent will find an answer in Dr. Bryan's letter. The subject is one which will not, we hope, be allowed to drop. EDITOR.]

### MODERATION IN SANITARY SCIENCE.

LETTER FROM LIONEL J. BEALE, Esq.

SIR,—I agree with you that it behoves all who regard the art of preventing disease as one of the greatest blessings of the progress of modern science, to take care that the doctrines of sanitary reform should not be pushed to an extreme. You are quite right in demanding more specific definitions of the kind of meat that should be condemned as unfit for human food. Some would condemn all that has not gone through the butcher's hands; but surely an ox or a sheep killed by collision with a railway train, or other accident, cannot from its mode of death be very much inferior to that which has undergone the operation of the butcher's implements. It would also be desirable to determine whether some chemical or other process, or some mode of cooking might not be discovered to render some of the meat which is now condemned, fit for human food. Again, it is a question whether animals which have recovered from pleuropneumonia, are not fit for food, although many adhesions of the pleura may remain. I think on these points we should not be entirely dependent on German or French inquirers, knowing as we do how much the general habits of the poorer classes in those countries, from the lower kind of food they eat, are more amenable to some diseases than our own population.

I am sure that sanitary science will get into some disrepute, if we are too stringent in our measures, and if we cannot always give a good reason for the faith that is in us. I have long asserted, and continue to believe, that we are too rash in condemning *all* superficial wells. I have had three under my inspection for several years, two contain on an average from forty to fifty grains of solid matter per gallon, and the other, often as much as eighty grains. All the pumps are well worked, and the water drunk in large quantities. I have authority from my vestry to close the worst of these at any moment. My inspector and myself have tried to find a case out against the water of these wells, but we have hitherto been unsuccessful. We have had the wells cleaned out several times, but have never found any great deposit either on the brick-work or at the bottom. One means of keeping a surface well in good condition is rapid consumption of the water; if a London pump is but little used the water in the well soon deteriorates. The best of my pumps is the most in use. I still believe that much might be done to render the large supply of water from the surface wells available for drinking purposes, and all who are sufficiently water drinkers to know the difference between the refreshing character of spring water in comparison with the mawkish stuff supplied by our London water companies, would rejoice at any means to preserve that high character which London spring water at one time universally maintained, and deserved.

You cannot do a better service to the cause of sanitary reform, than by a close criticism of all measures connected with it, as a means of establishing it in the favour of the public; for enthusiasm in any special causes is apt to lead us into excesses. Perhaps the present condition of the prison discipline system, and the excessive care taken of Sir J. Jebb's pet lambs, may be traced to overstrained working of the philosophy of health.

I am, etc.,

LIONEL J. BEALE,

*Med. Off. Health, St. Martin-in-the-Fields.*

London, January 1863.

## GRATUITOUS MEDICAL SERVICES.

LETTER FROM FREDERICK J. BROWN, M.D.

SIR,—The Medical Act is bearing good fruit; it is uniting the members of the profession into one faculty, whilst it admits of professional distinctions. As regards the public, the one thing needful is registration. Changes of every kind are springing up day by day in our profession, promoted, I believe, by the Medical Act. Amongst these changes, I include the general outcry of the profession for a cessation of gratuitous services to public charities. The pride of the heads of the profession made them, in times past, desirous of appearing superior to the acceptance of salaries. At the present moment, the dignity of Fellows and Members of the Royal College of Physicians would be hurt by suing at law for fees.

The same pride obtains amongst barristers; but it appears to me that this "chivalry" has nearly seen its day, both in law and medicine.

I do not think that there is an instance of the same sort of "chivalry" in the church. Clerics, after all, are less fantastic in money matters than their brethren of the forum and of the clinique.

Besides the pride of the profession itself, there has been another cause in operation keeping up gratuitous public services. This is a desire on the part of the public to drive a bargain with medical practitioners. It is commonly said that medical gentlemen are bad business men, and they often confirm this saying by their conduct.

In the matter of gratuitous public services, the public reason thus: Dr. A. or Surgeon B. will benefit himself vastly by this hospital appointment. He will be consulted by hundreds, and will become eminent and rich. Why pay him for benefiting himself? This style of reasoning reminds us of the custom of certain Oriental patients that demand a backsheesh from the doctor that attends them; for, say they, "Think of the great experience that you have gained by attending us." (See *Gadsby's Travels*.)

I wish to ask the members of our Association what they think of the scheme drawn up by the Chancellor for St. Bartholomew's Hospital at Rochester. The hospital will be opened after Midsummer, and is to be in charge of a resident surgeon. There will be a licentiate of the Apothecaries' Hall to act as a *pharmacien*, and there will be a consulting physician and a consulting surgeon. There will be fifty general beds, and thirty lock beds for women. The resident surgeon and the resident apothecary will receive salaries, but the consulting officers will not be paid. The duties of the consulting officers is to visit the hospital twice a week at least, so as to examine every patient on admission and on discharge (except Lock patients); and to attend the meetings of the Board. The duties, therefore, are those of examining as well as of consulting officers. They are to be ready to consult on all occasions, but they will not have the treatment of patients.

Now, I ask the members of our Association whether they think this scheme to be either practicable or just. The resident surgeon will have to prescribe for out-patients and to treat all the in-patients. It appears to me to be too much work for one man. Then it will be dangerous, I believe, for one man to attend thirty Lock patients as well as the general patients. Next, as to the consulting officers' appointment, it would be a loss of time to medical practitioners, without any compensation whatever; for there is not the professional pleasure afforded them of the care and treatment of patients.

I have brought the matter before the trustees of the charity, and before the public of Rochester and Chatham, deeming it my duty to our profession so to do.

It is a good case for an attempt to obtain an altera-

tion in the system of hospital services; for the charity is rich, being the oldest in England since the conquest. St. Bartholomew's Leper House Charity was founded in 1078.

I am, etc.,

FREDERICK J. BROWN.

Rochester, Feb. 9th, 1863.

## Medical News.

ROYAL COLLEGE OF PHYSICIANS. The following gentlemen passed the first part of the Professional Examination for the Licence of the College, on February 9th, 1863:—

Bryan, John Morgan, St. Mary's Hospital  
Burrell, Edwin, Guy's Hospital  
Hyde, Sidney, King's College  
Lovegrove, Washington, 34, Dowgate Hill  
Low, Alexander James, St. Bartholomew's Hospital  
Pyle, George Edward, Middlesex Hospital  
Squarey, Charles Edward, University College

## APPOINTMENTS.

COLES, Robert W., Esq., appointed Certifying Surgeon, under the Factory Act, for the District of Oldham, East.  
\*COULSON, William, Esq., appointed, by His Royal Highness the Prince of Wales, Sheriff of Cornwall, for the ensuing year.  
FREEMAN, Robert G., M.D., appointed Surgeon for the Greenwich District of the Royal Kent Dispensary.  
KAVANAGH, Patrick, M.D., appointed Surgeon for the Deptford District of the Royal Kent Dispensary.  
LESLIE, William, Esq., appointed Inspector, under the Factory Act, for the Aberdeen District.  
MURRAY, J. Jardine, Esq., appointed Surgeon to the Brighton and Sussex Infirmary for Diseases of the Eye.  
OLDHAM, James, Esq., appointed Consulting Surgeon to the Brighton and Hove Lying-in Institution.  
RIVINGTON, Walter, Esq., appointed Resident Medical Officer to the Tower Hamlets Dispensary.  
SAVERY, John, M.D., appointed Surgeon Extraordinary to the East Sussex Infirmary.  
WILL, James, M.D., appointed Inspector, under the Factory Act, for the Aberdeen District.  
\*WOLLASTON, Robert, M.R.C.P., appointed Physician to the Stafford General Infirmary.

## POOR-LAW MEDICAL SERVICE.

ALLISON, William, M.D., to be Medical Officer to the Clandy District of the Londonderry Union.  
ATKINSON, Frederick A., Esq., to be Medical Officer to the New Leake District of the Boston Union.  
CRAMER, Frederick A., L.R.C.P.Ed., to be Medical Officer to the Haubury District of the Droitwich Union.  
CRICKMAY, Edward, Esq., to be Medical Officer to the Dilwyn District of the Wobley Union.  
MCGREEVY, Neil, L.K.Q.C.P.L., to be Resident Apothecary to the Workhouse of the Lurgan Union, Armagh.  
MACKLEY, Herbert, Esq., to be Medical Officer to the Clackherton District of the North Brierly Union, Yorkshire.  
O'CONNOR, Laurence G., Esq., to be Second Medical Officer to the Clifden District of the Clifden Union, Galway.  
TIMMINS, Daniel, Esq., to be a Public Vaccinator for Dudley.  
TURNER, Edward W., Esq., to be Medical Officer to the Deddington No. 1 District of the Woodstock Union.

## ARMY.

FRANKLIN, Staff-Surgeon-Major H., from half-pay, to be Staff-Surgeon, *vice* J. T. Telfer.  
JOHNSTONE, Staff-Assistant-Surgeon John, M.D., to be Assistant-Surgeon 26th Foot, *vice* J. McLetchie.  
STEWART, Deputy Inspector-General A., retiring on half-pay, to be Honorary Inspector-General of Hospitals.

To be Staff-Assistant-Surgeon:—

CRAWFORD, Assistant-Surgeon J. R., 69th Foot.

## ROYAL NAVY.

BAYNES, W. W., Esq., Staff-Surgeon, to the *Indus*, for the *Canopus*.  
GEORGES, Thomas E., Esq., Assistant-Surgeon, to the *Asia*, for the *Hambal*.  
GINLETT, Hart, M.D., Surgeon, to the *Asia*, for the *Hambal*.  
HADLOW, Henry, Esq., Assistant-Surg. (additional) to the *Fisgard*.  
KEPLING, Thomas, Esq., Assistant-Surgeon, to the *Indus*, for the *Canopus*.  
MC CARTHY, Charles D., Esq., Surgeon, to the *Vigilant*.  
MINNOCH, Alexander, Esq., Assistant-Surgeon, to the Woolwich Division of Marines.

**VOLUNTEERS.** (A.V.—Artillery Volunteers; R.V.—Rifle Volunteers).—

SEALE, J. L., M.D., to be Assistant-Surgeon 2nd Wiltshire R.V.

To be Honorary Assistant-Surgeon:—

VYE, E., Esq., 4th Devonshire R.V.

**DEATHS.**BLACKMAN, Matthew, Esq., Surgeon, at Whitstable, on Feb. 4.  
BROOKS, Richard B., Esq., formerly of Chelmsford, at Madeira, aged 27, on January 12.\*COLLYNS, William, Esq., at Chudleigh, Devon, on January 15.  
HOLMES, On February 8th, at 11, Great Coram Street, Louisa

Theresa, widow of the late James Holmes, Esq., Surgeon R.N.

LAING, On February 7, at Aberdeen, Mary G. T., widow of Francis

Laing, M.D., Staff-Surgeon.

PACKMAN, William S., M.D., of Clarges Street, at Alexandria, aged

45, on January 24.

WHITE, Peter, Esq., late Surgeon 72nd Regiment, at Brompton, aged

82, on February 5.

\*WILLIAMS, R. Parry, Esq., at Bron Offa, near Wrexham, lately.

WIXSTON, David, Esq., late of Haverstock Hill, aged 39, on Feb. 1.

Mr. CUBITT has resigned the office of President of St. Bartholomew's Hospital.

Dr. HARLEY has been elected a corresponding member of the Royal Academy of Sciences, of Bavaria.

**SUCCESSFUL MIDWIFERY.** Only nine fatal cases have occurred in 3,549 deliveries effected during 1862, at the Royal Maternity Charity.**ARMY MEDICAL OFFICERS.** Each medical officer in an army has made his charge an average of 241 soldiers, exclusive of soldiers' wives and children.**UNIVERSITY OF OXFORD.** Dr. Rolleston and Sir Benjamin C. Brodie, Bart., have been nominated examiners for the Burdett Coutts scholarship.**REJECTIONS OF RECRUITS.** About 350 per 1000 of those who present themselves for medical examination as recruits, are rejected on account of physical disability.**BIRTHS IN 1862.** During the past year 711,601 children were born in England and Wales, amounting to an average of 1,950 *per diem*. This is the largest number of births ever recorded as occurring in this country.**SANITARY STATE OF WINDSOR CASTLE.** We are glad to find from a report of Mr. Rawlinson, that he believes Windsor Castle to be the most complete in sanitary works, appliances, and arrangements of any large building in existence.**CONGRÈS INTERNATIONAL DE BIENFAISANCE.** The publication of the *Compte Rendu* of the recent London Session is in progress. The foreign papers and reports will be in French, forming one volume; the English papers and reports in English, forming a second volume.**CARBONIC ACID AS AN ANÆSTHETIC.** M. Ozannan has given a mixture of three parts carbonic acid with one part of atmospheric air with success as an anæsthetic. After breathing it for ten minutes the patient became insensible, and an operation was performed without his evincing any sign of pain.**ROYAL INSTITUTION.** At a general monthly meeting, held on the 2nd instant, the secretary reported that the executors of the late James Walker, Esq., F.R.S., M.R.I., had bequeathed to the Institution a marble bust of Professor Faraday, by Mr. Matthew Noble, M.R.I. The thanks of the members were returned to Professor Tyndall, and to his Eminence Cardinal Wiseman, for their discourses on the evening meetings on Fridays, January 23 and 30.**NON-COMBATANTS.** Dr. Detmold of New York says in his lectures as military surgeon:—"In case of a disaster to the army, such as a hasty strategic movement, change of base, or whatever else the commanding general may

choose to call it, where the wounded are left behind, I need not say that the surgeon must remain with the wounded, that is, a sufficient number of surgeons must be left behind to take care of the wounded which fall into the hands of the enemy. It is beginning to become an established custom no longer to make prisoners of war of the surgeons; they are non-combatants, and as they extend a helping hand to all wounded, whether friend or foe, so should their sacred calling protect them; and wherever surgeons have been captured of late they have, I believe, invariably been unconditionally released."

**UNIVERSITY COLLEGE, LONDON.** On Saturday last, the result of the last year's competition of three candidates for the clinical gold and silver medals, instituted at the suggestion of Dr. Elliotson by the late Robert Fellowes, LL.D., for the best observations on the medical cases in the hospital, was reported by the examiners, Dr. Walshe, Dr. Garrod, Professor Jenner, and Dr. Hare. The council, on the recommendation of the examiners, in consideration of the very high order of merit of all the papers sent in, awarded as follows: the first place and the gold medal to Mr. Talfourd Jones, the second place with an extra gold medal to Mr. Frederick T. Roberts; the third place with the silver medal to Mr. Richard Dawson.

**SCHOLARSHIPS IN NATURAL SCIENCE AT SIDNEY SUSSEX COLLEGE, CAMBRIDGE.** This College has just issued a notice that two scholarships, of the value of £40 per annum each, will be given this year for natural science, the examination to commence on October 13th; the subjects being electricity, chemistry, geology, and anatomy (human osteology and general anatomy). The scholarships are perfectly open. The successful candidates will be required to enter at the College. Further information may be obtained from the Rev. J. C. W. Ellis, tutor of the College. Other scholarships, ranging in value from £32 to £80 per annum, are to be competed for at the same time.

**INFECTIOUS DISEASES AND PUBLIC CONVEYANCES.** In the House of Commons, on Monday, Dr. Brady asked the Secretary of State for the Home Department if his attention had been directed to the evils resulting from persons labouring under infectious diseases being carried to hospital in public conveyances; and, if so, if it be his intention to introduce any measure this session with a view to remedy the same. Sir G. Grey said his attention had not been called to the subject except by reading letters in the newspapers. The subject had been discussed when the Hackney Carriage Act was before Parliament, and a clause had been proposed to meet the difficulty suggested by the hon. gentleman. On discussion, however, the clause had been withdrawn. It was in the power of parochial authorities to deal with the matter by their own private acts, and some of them kept carriages for the purpose of conveying persons to the hospital. He thought the driver of a public conveyance would be justified in refusing to convey a person labouring under an infectious disease. In reply to a further question from the hon. member, the right hon. gentleman the Home Secretary said, so far from having any objection to the hon. member introducing a bill to remedy the evil, he should be much obliged to him to do so, that he might know in what way he proposed to deal with the question.

**REGISTRATION IN IRELAND.** In the House of Commons, on Monday last, Sir Robert Peel moved for leave to introduce a Bill on this subject. He said that a system of registration would be of immense utility. It would be very beneficial, for instance, in promoting sanitary reforms. If correct data could be obtained as to the health of the people, measures would be more promptly and effectually taken to mitigate disease. All

classes will be benefited by its adoption in Ireland, not as a mere registration of births and deaths, but as a plan for bringing annually before the public, as in England and Scotland, the causes affecting the health of the community. Ireland is almost the only civilised country in the world where no such system of civil registration of births and deaths exists. The English Act was passed in 1836. It caused a good deal of agitation at the time, but it has worked admirably. The passing of the Scotch Act was even more strongly opposed, and it was not until 1854 that the opposition was overcome. The Scotch Act is an improvement upon the English one. In the present Bill, he adopted a system in conformity with that in operation in England—so that the areas or districts will be the areas of the unions, the dispensing medical officers of the unions will be the registrars, and the clerks of the unions will be the superintendent registrars. The Poor-law districts are well known, whereas considerable inconvenience would have resulted in that respect from the employment of the constabulary. In Ireland, besides 163 unions, we have 718 dispensary districts with 777 dispensary medical officers—thus forming an admirable machinery ready to our hand. As to expense, the deputations from the College of Surgeons of Ireland, the Statistical Society, and the Social Science Association, all recommended that the remuneration of the registrars should be defrayed from the local rates, but that the superintendent registrars should be paid out of the Consolidated Fund. He proposed that the registrars should be paid, as in England, out of the rates, but that the superintendent registrars should receive their fees out of the Consolidated Fund. Considering the advantage that will be derived by all classes from this measure, the total burden that will be thrown upon the public will be comparatively very trifling—namely, £10,000. He proposed to pay the registrars 1s. for each entry, and the superintendent registrars 2d. There will be no other outlay attending the scheme except the salary of the Registrar-General, to be increased to £1,000 a year. "We require by this Bill the compulsory attendance of the parties. This is absolutely necessary; and Registrar-General Graham says the want of it is one of the chief blots in the English system. The only other point on which I need trespass on the time of the House is a very important one—namely, the medical certificates. We wish to make our scheme as complete as possible, in order to obtain not a mere registration of births and deaths, but a scientific record of vital statistics, and with that view we have introduced into our Bill a provision which we think will meet the approval of the medical officers. We have not desired, as is done in Scotland, to make it binding on them penally to give the return. From the opportunities I have had of conversing with the President of the Royal College of Surgeons, and judging also from other sources of information, I believe that the medical officers generally, will be prepared to co-operate with the State, and to furnish it with the requisite particulars as to the deaths of persons whom they may have attended professionally with greater readiness if it is left to them to do it freely, instead of its being made compulsory on them by the insertion of a penal clause." Lord Naas could not congratulate the right hon. baronet on the experience he had gathered during the recess, for it was to be feared that he had got into the hands of the doctors, and very few men were much the better for that. Of all the schemes propounded for obtaining these important statistics, that which called in the aid of the doctors was the worst. Many of the dispensary doctors were eminent in their profession; they were in large practice, their time was occupied from morning till night. In his opinion, doctors, of all others, were the most unsuitable for the performance of these duties in Ireland. Dr. Brady maintained that medical men were of all classes the best qualified to act as registrars. In this country butchers and bakers were ap-

pointed registrars, who, in copying the cause of death from the medical certificate, were often totally at a loss, being ignorant of the professional meaning of the terms employed. Mr. Maguire thought that however great a calamity it might be to fall into the hands of the doctors, it would be still worse to fall into the hands of the public. After a few words from Sir R. Peel in reply, leave was given to introduce the Bill.

**MORTALITY DURING LAST QUARTER.** The mortality in England and Wales in the last quarter of 1862 was at the rate of 2.226 per cent.; in 1860 it was 2.043; in 1861, 2.061. Though the autumn of 1862 was not as a whole colder than those of 1860 and 1861, the sudden invasion of cold in November, and the abrupt succession of heat account for its having been the most fatal. The north-western counties, York-shire, London, the northern counties, and the west midland are the five divisions in which the highest rate of mortality prevailed. In the first, which contains the districts of the cotton manufacture, the rate—2.66 per cent.—was higher than in any other division. This distinction is not of recent birth; it is not the fruit of adverse circumstances, but has sprung from causes which have been in operation since Liverpool, Manchester, and other towns, in what has been called the worst drained part of England, rose into importance as seats of commerce and manufacture. But whatever be the sanitary condition of the towns and villages they inhabit, human beings must be affected by the atmosphere in which they are immersed, and the effects of which they can but partially control; and as the cotton districts participated with the rest of the kingdom in the benefit of a healthy summer, they have also suffered, like other parts, from a less healthy autumn. . . . Scarlatina and diphtheria, and also diarrhoea, prevailed to a considerable extent in Manchester. An increase of deaths in Ashton-under-Lyne is attributed to scarlatina and measles. Scarlatina caused eighty deaths, being a third part of the total number, in Oldham-above-Town; these occurred not only in the working-class, but in the general population. In Blackburn and Witton the mortality was increased by measles and bronchitis, and at the latter place there was "much sickness in consequence of the damp weather." The mortality in the Chorley subdistrict was nearly doubled, chiefly by measles, and the weather, "mild and damp," was considered unfavourable to health. The deaths in the districts of Liverpool rose from 1,883 and 2,193 in the corresponding quarters of 1860 and 1861 to 2,625 last quarter; those in West Derby rose from 1,111 and 1,472 to 1,726. A great part of this formidable increase has been caused by the ravages of scarlatina. This disease caused 50 out of 105 deaths in the Clowance subdistrict in Devonshire. Of 203 deaths in Kingstown (Portsea Island) no less than 126 were those of children from scarlatina or other fever and croup. A very malignant form of scarlatina raised the deaths much above the average at Halstead, in Essex, and it is reported in many other parts. Diphtheria caused a third part of the mortality at Hailsham, in Sussex, and it has been very prevalent in the neighbourhood of South Walsham, in Norfolk; 13 out of 34 deaths from all causes being from this disease. Diphtheria was very prevalent in the subdistrict of Diss, Norfolk, and trebled the average mortality in the parish of Dickleburgh. Measles has been unusually rife and fatal in Falmouth, hardly a family with children escaped, and many adults were attacked by it. (*Registrar General's Quarterly Report.*)

**LANSDOWNE HOUSE LIBRARY.** The library itself was exquisitely decorated by Cipriani in imitation of the antiquities found in Herculaneum, and it was while occupied in this superb temple, as the librarian, philosopher, and friend of Lord Shelburne, that Priestly made the discovery of oxygen.

## OPERATION DAYS AT THE HOSPITALS.

MONDAY.....	Royal Free, 2 P.M.—Metropolitan Free, 2 P.M.—St. Mark's for Fistula and other Diseases of the Rectum, 1.15 P.M.—Samaritan, 2.30 P.M.—Lock, Clinical Demonstration and Operations, 1 P.M.
TUESDAY.....	Guy's, 1½ P.M.—Westminster, 2 P.M.
WEDNESDAY....	St. Mary's, 1 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.
THURSDAY.....	St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—London, 1.30 P.M.—Great Northern, 2 P.M.—London Surgical Home, 2 P.M.—Royal Orthopædic, 2 P.M.
FRIDAY.....	Westminster Ophthalmic, 1.30 P.M.
SATURDAY.....	St. Thomas's, 1 P.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.	Medical Society of London, 8.30 P.M. Mr. Thomas Bryant, Lettsomian Lecture "On the Differences between Surgical Diseases of the Nervous, Respiratory, Circulatory, Digestive, and Urino-Genital Systems of the Child and the Adult."—Asiatic.
TUESDAY.	Statistical.—Pathological.—Ethnological.
WEDNESDAY.	Society of Arts.—Geological.
THURSDAY.	Zoological.—Royal.—Antiquarian.—Linnæan.—Chemical.—Harveian.
FRIDAY.	Royal College of Physicians, 5 P.M. Dr. Pavy. Gulstonian Lectures. "On the Amyloid (so-called) and Fatty Degenerations."—Geological.—Royal Institution.—Western Medical and Surgical, 8 P.M. Dr. Anstie, "On the Therapeutical Value of Cod-Liver Oil in Convulsive Diseases."
SATURDAY.	Association Medical Officers of Health.

## TO CORRESPONDENTS.

\*. All letters and communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen St., Lincoln's Inn Fields, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

THE TITLE OF DOCTOR.—From press of other matter, we must defer until next week the publication of many letters which we have received on the subject of the Title of Doctor.

PELLAGRA AND ECZEMA.—SR: The great interest which attaches to that rare disease, pellagra, may perhaps excuse so remote an allusion as the following to the subject. It will occur to some of your readers to have seen chronic eczema of both hands and both arms, with light mulberry tinge, a constricted, rather dry, shining surface, stiff attenuated fingers, and a decrepit posture of the hands: such cases are seen in persons of a poor habit and enfeebled constitution. They have been pointed out to me by those who have seen pellagra, as bearing a considerable resemblance to that disease. The opinions of M. Bielt are well known; viz., that pellagra depended upon a gastro-intestinal irritation for its proximate cause. If it be so, the two diseases are brought into yet nearer affinity, as the early treatment of eczema rests upon that hypothesis. Eczema, too, results from over fatigue, and we may suppose from nervous exhaustion generally. It might be serviceable to inquire whether such cases as I have described above, occur in establishments allotted to insane patients. I must add that M. Bielt had great opportunities of studying this disease in Italy.

I am, etc., GEORGE GASKIN.

3, Westbourne Park, February 9th, 1863.

COMMUNICATIONS have been received from—MR. WILLIAM COPPEY; DR. RODEN; MR. ANGELL; MR. R. DUNN; DR. WILLIAM BUDD; L.R.C.P. ED. & F.R.C.S. ED.; MR. T. WINDSOR; MR. JOSEPH HINTON; MR. R. S. FOWLER; ENQUIRER; MR. A. BALL; DR. JAMES RUSSELL; MR. H. NORRIS; DR. R. JONES; MR. STONE; DR. LIONEL BEALE; MR. BUCKNILL; THE HONORARY SECRETARIES OF THE WESTERN MEDICAL AND SURGICAL SOCIETY; MR. GEORGE GASKIN; DR. G. M. HUMPHRY; DR. F. J. BROWN; DR. THOMAS BOYCOTT; DR. DAVEY; DR. R. WOLLASTON; DR. F. T. PONCIA; MR. W. PARKY; MR. C. VASEY; DR. STEYAR; DR. BRYAN; MR. JOHN PARKS; DR. B. W. FOSTER; MR. DAYMAN; MR. C. R. THOMPSON; MR. A. NAPPER; MR. R. W. FAYNS; DR. MARLTON; MR. HAYNES WALTON; DR. KIDD; MR. C. F. BROWN; DR. H. MARSHALL; and AN OLD ASSOCIATE.

## ADVERTISEMENTS.

## Liquor Bismuthi, (Schacht)—a

fluid preparation of Bismuth, not decomposed by dilution. This article has been extensively used at the Bristol General Hospital, and in private dispensing, since 1857; and is recommended by many of the faculty as more efficacious and more convenient of administration than any other form of the remedy.

Prepared by G. F. SCHACHT, Chemist, Clifton.

London Agents: Messrs. DREW, BARRON, & CO., Bush Lane.

## Aloina.—The discoverers of this

(vide "Edinburgh Monthly Journal of Medical Science for Feb. 1851), the CRYSTALLINE PURGATIVE PRINCIPLE OF ALOES, continue to prepare and supply it. They have the gratification of knowing that the most eminent of the profession prescribe it, to the exclusion altogether of the various kinds of aloes. Orders executed direct or through any Drug house, by T. & H. SMITH & CO., 63, Coleman Street, London, and 21, Duke Street, Edinburgh.

## Jozeau's Copahine Mege.

Or SACCHARATED CAPSULES. — Copahine and Cubebs are doubtless the best remedies, but these drugs are of a repulsive taste and odour, and occasion colicky pains, nausea, and gastric disturbance. M. Jozeau has succeeded in rendering these valuable therapeutic agents perfectly innocuous, by increasing, in his Copahine, all the curative properties. This preparation has been adopted by the Paris Academy of Medicine, after more than a thousand trials in Paris, and the different London Hospitals, viz., St. Thomas's, Guy's, and St. Bartholomew's, under the care of Messrs. Lloyd, Poland, and Le Gros Clark, "Lancet" Nov. 6, and Dec. 10, 1852. The Copahine which is in form of a pretty pink sugar-plum, effects a cure in about six days, either in recent or chronic diseases. 100 Capsules, 4s. 6d. at G. JOZEAU'S, French Chemist, 49, Haymarket, London; 22, Rue St. Quentin, Paris; and all the most important Chemists.

## For Varicose Veins and Weak-

NESS. Very superior SURGICAL ELASTIC STOCKINGS and KNEE-CAPS, on a New Principle, pervious, light in texture, and inexpensive, yielding an efficient and unvarying support, under any temperature, without the trouble of Lacing or Bandaging. Likewise, a strong low-priced article for Hospitals and the Working-classes.

ABDOMINAL SUPPORTING BELTS for both Sexes, those for Ladies' use, before and after accouchement, are admirably adapted for giving adequate support with EXTREME LIGHTNESS—a point little attended to in the comparatively clumsy contrivances and fabrics hitherto employed.

Instructions for measurement and prices on application, and the articles sent by post from the

Manufacturers,  
POPE and PLANTE, 4, Waterloo Place, Pall Mall, London.  
The Profession, Trade, and Hospitals supplied.

## TO ADVERTISERS.

## British Medical Journal. —

Office, 37, GREAT QUEEN STREET, LINCOLN'S INN FIELDS, LONDON, W.C. Published every Saturday.

The BRITISH MEDICAL JOURNAL is transmitted direct from the Office to between two and three thousand Members of the British Medical Association in all parts of the United Kingdom, among whom are the Medical Officers of most Hospitals and Dispensaries, and the majority of the leading members of the profession. It is also taken in by many Libraries and Medical Societies. As a medium for immediate communication with the medical profession, it offers excellent facilities to advertisers of books, drugs, instruments, situations, etc.

## SCALE OF CHARGES FOR ADVERTISEMENTS.

Five lines and under .....	£0 2 6
Each additional line .....	0 0 6
Each ten lines .....	0 4 6
A whole column .....	1 15 0
A page .....	3 5 0

When a series of insertions of the same advertisement is ordered, a reduction is made on the above scale, in the following proportions.

For 6 insertions, a deduction of 10 per cent.	
For 12 or 13 " " " "	20 "
For 26 " " " "	25 "
For 52 " " " "	30 "

Advertisements ought to be delivered at the Office on or before the Thursday preceding publication; and, if not paid for at the time should be accompanied by a respectable reference.

Post-Office Orders are to be made payable at the Western Central District Office, High Holborn, to THOMAS JOHN HONEYMAN (the Publisher), 37, Great Queen Street, Lincoln's Inn Fields, London, W.C.

# Short Clinical Lectures

ON

## THE FIRST PRINCIPLES OF MEDICINE.

*Delivered at King's College Hospital.*

BY

LIONEL S. BEALE, M.B., F.R.S.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS; PROFESSOR OF PHYSIOLOGY AND OF GENERAL AND MORBID ANATOMY IN KING'S COLLEGE, LONDON; PHYSICIAN TO KING'S COLLEGE HOSPITAL; HONORARY FELLOW OF KING'S COLLEGE; ETC.

### I.—SOME OBSERVATIONS ON THE NATURE OF CERTAIN HEALTHY AND MORBID CHANGES, AND ON COUNTERIRRITATION.

I PROPOSE this morning to direct your attention to a plan of treatment which I believe is adopted, in many cases of disease, by every practitioner in the present day, which is employed in every civilised country and by some savage nations, and which has been in use from the very earliest ages.

Recent careful observation has compelled us to doubt if many remedial agents which have been held in the highest repute really exert the influence which was formerly attributed to them; but of the benefit of counterirritation few practitioners have any doubt. Indeed, until I recently read a lecture of Dr. Chambers's, I thought we were all agreed, not only with respect to the beneficial action of this plan of treatment, but also as to the principle upon which it is enforced. I have always been taught that by counterirritation we seek to establish an increased action in one tissue or organ, for the purpose of diminishing an increased action which is taking place in another tissue or organ, the due performance of whose function is of great importance to the organism.

Dr. Chambers, however, tells us—but I think few will agree with him in his statement—that the idea of counterirritant practice is to substitute one *disease* which is “less dangerous and painful, or whose disorganising tendencies are but temporary,” for another *disease* which may be dangerous or painful, or which tends to disorganise the body;” and yet the author of the *Renewal of Life* has admitted, as examples of counterirritation, purgatives to relieve a cold on the chest, and excessive diuresis for dropsical swelling? Are ordinary temporary purgation and excessive diuresis, diseases? After stating that it is probable “that future physiologists may be able to explain in another way the instances which seem (!) to favour the system,” he says that “in the meantime it appears unwise to adopt, as a principle, the estimation of the utility of our drugs by the power they possess of making a sound man ill” (!). Now what does the word “ill” in this sentence mean? When our bowels act a little more than usual; when we pass four pints of urine instead of two in the twenty-four hours; when we perspire freely; if we apply a turpentine stupe or a mustard poultice to our sound and healthy skin,—do we necessarily become ill?

The idea of counterirritation clearly is, not to

establish one disease for another, but to increase the action of one or more tissues, with the view of reducing the increased action which is already going on in other and more important tissues or organs.

It seems to me that much of the obscurity which occurs when an attempt is made to account for changes, and to explain various actions, results from the effort to define the *diseased*, as distinguished from the *healthy* state. The best plan, therefore, in discussing morbid actions and changes, is simply to try to ascertain with accuracy what *is* going on, and contrast it with what physiology teaches us ought to go on.

If we make an attempt to define exactly what is meant by the substantive *disease*, or by the adjective *morbid*, great confusion must result; and for this simple reason, that we cannot separate by any distinct line healthy actions from morbid actions, or the *healthy* state from the *diseased* state. Of course, a small contracted liver or kidney, doing one-tenth of the work healthy organs would do, and exhibiting the most obvious alterations of structure, are diseased. They have, however, not passed suddenly from the healthy to the diseased state, but by very insensible gradations, so that, had you seen the organs in an early stage, you would not have been able to point out any differences by which they could certainly have been distinguished from healthy organs, although, had you examined the secretions formed by them, you might have obtained evidence of change in quantity or quality. Up to a certain point, although there may have been excessive or deficient action, you could not have spoken of the condition as one of disease.

Nor can we define disease as increased or diminished action—increased or diminished vitality; for in some diseases tissues grow too fast, in others the structures or organs are reproduced too slowly. Disease may consist of an *excess of action*, or there may be *deficient action*. The tissue may live too fast, or it may undergo its changes more slowly than in health. There is in many morbid structures or products a greater activity, a more rapid conversion of pabulum into living matter, than in health. A certain bulk of epithelial or other form of cancer, or of pus, or of the lymph occupying the air-cells of a pneumonic lung, exhibits greater evidence of vital activity than the same bulk of healthy tissue. It grows faster; it appropriates nourishment faster; and this nourishment more quickly becomes converted into tissue; or is transformed into compounds, totally different from those existing in it before its appropriation, far more actively than in a normal tissue. *The conversion of inanimate pabulum into living matter, which in health takes place under certain restrictions, takes place in these instances under restrictions very much diminished.*

To say, then, that “disease is not a new excess of action, but a deficiency; not a manifestation of life, but partial death,”—is stating that which is opposed to most important facts of general observation, and is strangely at variance with the facts demonstrated by very many observers in the present day.

Nor can I agree with Dr. Chambers in his statement that “the business of the physician is directly or indirectly not to take away material, but to add;

not to diminish function, but to give it play; not to weaken life, but to renew life." We very often desire to take away material, as when any organ is the seat of greatly increased action. We try to get rid of the lymph in an inflamed lung, the matter poured out into the areolar tissue and other tissues in inflammation, or into the joints and fibrous tissues in gout and rheumatism. Not only so, but the blood itself often contains matters which we desire to get rid of; so that we really often have to take away material; and if we could but diminish the supply of blood to many organs at the right moment, and for the right time, we might possibly prevent a diseased action from being developed.

So, again, it seems to me that we really do often desire to diminish function. When an organ is deranged, is it not a principle established by experience, and does it not accord with common sense, to try to *diminish its action*, and make some other organ do its work for the time? The last advice given to the physician, "not to weaken life," seems to me to require explanation; for surely, if we could "weaken the life" of a cancer, it would be just what we desire; and if we could but prevent it from *renewing its life*, we should be doing more than medicine dares at present to hope ever to achieve.

I have drawn your attention to these points, because it seems to me that the dogmas insisted upon by my friend are opposed to the principles of sound physiology, and to the teachings of the bedside, while they are not supported by any new observations of his own; and because the very positive exposition of his peculiar views in his first lecture seems to me to demand our attention; and I therefore take this opportunity of discussing some of the first principles upon which our science is based.

I cannot help thinking that Dr. Chambers has assailed some notions which are very much nearer the truth than the substitutes he proposes; and I do not think that the statement that "disease is a deficiency of action and partial death," as a general principle, can be received or sustained. It is also incorrect to talk of "life-giving articles". Nothing gives life, save that which has life; and this is, at any rate, a sound truth, from which all our speculations upon the essential nature of healthy and morbid changes in living structures must start.

[To be continued.]

**MEMORIAL TO THE LATE DR. CUSACK.** A very handsome memorial has been erected in St. Anne's Church by the subscriptions of the friends and admirers of the late eminent physician, W. Cusack, M.D. The memorial consists of a very tasteful stained glass window at the north side of the apse. (*Dub. Med. Press.*)

**PHOTOGRAPHIC STATISTICS.** Some very interesting statistical facts, relating to the immense consumption of photographic chemicals by the London Stereoscopic and Photographic Company, have recently been made public. The number of glass negatives taken at the exhibition (from which the paper pictures are printed) amount to very many thousands. The paper used was 300 reams; albumen for ditto, about 280 gallons; nitrate of silver, 4,000 ounces; gold, 90,000 grains; hyposulphite of soda, 4,800 lbs. The photographic pictures produced from this immense amount of material are now approaching 1,000,000. (*Post Magazine.*)

OF

## HOSPITAL PRACTICE:

METROPOLITAN AND PROVINCIAL.

### BIRMINGHAM GENERAL HOSPITAL.

CASES OF RHEUMATIC PERICARDITIS.

Under the care of JAMES RUSSELL, M.D.

[Continued from page 163.]

THE next case appears one of typhoid pericarditis, remarkable from its mildness as compared with the attendant symptoms, and more so from the singular persistence and recurrence of symptoms allied to typhoid fever on more than one occasion.

CASE v. Anne Tibbets, aged 37, a nurse in the hospital, had never had rheumatic fever; nor was she aware that she inherited any rheumatic tendency. She had been very assiduous in her attendance upon some cases of typhoid fever, and especially upon one of great severity, which was admitted on January 17th 1862, and was not convalescent until February 8th. On that day, she was taken with shivering, heat of skin, and great depression, together with soreness of throat, without any morbid appearance presenting itself in the interior of the fauces. On the 10th, a sharp eruption of herpes appeared on her lips. The fever did not subside until the 12th, when she was able to sit up for a short time. From that date until the 19th, she walked about the ward, but was very feeble, occasionally shivered, and complained of severe pain between the shoulders, and of tightness across the chest.

On February 19th, she was very poorly; had sharp cutting pain across the chest, through each breast, and round the shoulders. In the evening, she was seen by Dr. Maxwell, from whose notes I have extracted the preceding report. He found her greatly exhausted, and looking very ill. Careful examination of the chest did not detect any morbid signs in that region, excepting very rapid and irritable action of the heart. The sounds of the heart were perfectly clear.

She passed a very restless night, and spoke next morning very urgently of the pain she had suffered in the neck and chest; which, however, was somewhat relieved by the application of warm flannels. At 4, an opiate draught procured ease. At 7, Dr. Maxwell, at his visit, detected the physical signs of pericarditis.

2 p.m. The pulse and respiration were 124 and 32. There was much moaning; the face was very pinched; aspect exceedingly typhoid; tongue very dry and fissured; skin dry. A fine pericardial friction-sound was heard, chiefly with the *diastole* of the heart. When first heard in the morning, it was double, very loud and coarse, and was distinct over the entire cardiac region.

R. Ether. chlorici ʒij; tinctura cardamomi comp. ʒss; aquæ ʒviiss. M. Sumat ʒj 4tis horis.

She was ordered to have six ounces of wine.

During the following two days she remained in much the same state. She lay on her back, and was very languid. There was no delirium, excepting some confusion during sleep. Pulse 80, labouring, and presenting an interval after every third beat. She complained of some pain in her left shoulder. Her abdomen was soft, free from distension and from eruption. There was no diarrhoea. The friction-sound continued to be chiefly *diastolic*, and the cardiac dulness was not extended. The pulmonary signs were normal. She had been ordered half an ounce of brandy every second hour.

On the 23rd, improvement was decidedly visible. The pulse was 60 to 65, frequently intermitted. The friction-sound was harsh and *systolic*. On the 25th, she desired solid food. On the evening of March 8th, the patient suffered from an attack of orthopnoea, with much fluttering of the heart; and on the following day a more severe paroxysm occurred, having the characters of angina pectoris. The systolic friction-sound, which was noted on the 4th to be hardly distinguishable, was again very loud. A blister was applied to the cardiac region. The pain and dyspnoea were relieved by two draughts containing opium and chloric ether. She left on March 30th. The friction-sound was then not quite inaudible; but in June, when she returned, the pericardium was quite silent.

She continued equal to her duties from the last mentioned date, though they were at times very laborious. Early in August she went for a holiday to Coventry. Whilst there she again became ill and depressed, and suffered from diarrhoea, sickness, and entire loss of appetite. She returned to take to her bed, but was sent out convalescent on September 24th; but, four days afterwards, was again received, very feeble, with a running, vibrating pulse.

She came under my care on the 12th of the month, with all the symptoms of typhoid fever. The symptoms were not alarming, though sufficiently severe; obstinate vomiting was very prominent. No eruption appeared, but diarrhoea was present to a moderate degree. She did not leave her bed until the last week in October, a relapse having been occasioned by premature indulgence of her desire for solid food. From that period her recovery progressed satisfactorily; and at the present time she is actively employed in the hospital, in perfectly good health. There were no symptoms of any cardiac affection during the last illness.

The concluding two cases are of a more ordinary character; but each suggests some interesting points respecting the diagnosis from physical signs; and the former of the two also presents a remarkable abnormality in the heart's action preceding the development of the pericardial inflammation. A curious question also suggests itself with reference to the second case—whether the present were the first attack of pericarditis from which the patient had suffered. She presented a serious rheumatic history, implicating the heart, which retained distinct traces of former mischief inflicted on the mitral valve. If a previous pericarditis had occurred, the heart must have been left sufficiently free from adhesion to develop a renewed rubbing sound.

CASE VI. Robert Goodman, aged 15, fireproof-safemaker, was admitted January 31st. He had been ill five weeks with irregular rheumatic pains. He had never had rheumatism before; nor could any hereditary tendency to that disease be discovered. He was very anemic, looked feeble, and was not well nourished. The impulse of the heart was very abrupt, and a diastolic aortic bellows-sound was at once distinguished.

He continued to suffer from irregular rheumatism, with effusion in his left knee, and a deposit of red urates in his urine. On February 11th, the normal sounds of his heart presented a remarkable character. They occurred in two regularly alternating sets; one set consisting of two or three successive cardiac sounds, of normal distinctness, followed, after a distinct pause, by the same number exceedingly faint and distant, suggesting to one the ringing of a peal of bells half muffled. The first sound of the heart had a ringing character. The rheumatism at this time had increased in severity. Three days afterwards, a suspicion arose of the commencement of pericarditis; but the suspicion was not converted into certainty by distinct sounds until four days longer.

The general symptoms of the disease were not severe; but the period of illness was prolonged by the feeble state of the patient's health. His pulse was quick and

irritable; he emaciated considerably; his urine was loaded with light coloured urates. He left his bed for the first time on March 3rd, and the hospital on April 11th.

The physical signs merit a somewhat more careful notice. No evidence of fluid effusion, beyond a small amount, presented itself. Once only was there a suspicion, not confirmed, of left pleurisy. The pericardial friction-sound was double, and was heard beneath the sternum, and to its left side over the region of the heart, with greatest distinctness over the fourth cartilage and third space; it was not heard at all on the right of the sternum, unless firm pressure were made, when it was immediately produced. The friction-sound never overcame the aortic diastolic sound. No *frottement* was ever present. On February 25th, the sound presented a variation which illustrated the similarity, under certain circumstances, of a rubbing and a bellows-sound, and also the obstinate duration of a rubbing sound. A loud harsh single murmur, following the first sound of the heart, was discovered at the apex, occupying a limited space; this murmur, which in quality was not distinguishable from a blowing sound, remained; it was quite separate from the aortic sound, and an exchange between them was effected at the fifth cartilage, where there existed a neutral spot, neither one nor the other sound being heard. The murmur in question was loudest in the fifth space beneath the nipple (just at the apex), and ended at the axillary line, not being audible behind. It was observed on one occasion to be much influenced by the degree of pressure exerted by the stethoscope. When the patient left, the sound was still distinct; but, at a visit paid a month afterwards, it had perfectly ceased—strong presumptive evidence, conjoined with the limited space over which it was audible and the effect produced upon it by pressure, in favour of its exocardial origin.

CASE VII. M. A. Everts, aged 17, servant, was admitted December 30th. Her mother had one attack of rheumatic fever. The patient's first symptom of rheumatism presented itself six years ago, when acute rheumatism confined her for six weeks; she had then severe pain in her heart, and was blistered. Every returning winter the attack has recurred, lasting usually from one to three months; and each time she was blistered over the heart.

She was a delicate looking girl, with a light complexion and irritable temperament, but tolerably well nourished. She entered the hospital for rheumatic pains in her joints, but was without fever. The impulse of the heart was seen extending nearly an inch to the left of the nipple, though there was no abnormal dullness; and was abrupt. At the apex, a sharp shrill mitral bellows-sound was audible; it was also audible posteriorly; was heard over a remarkable extent of surface, even from the occiput to the sacrum. The aortic valves appeared healthy. The first and second sounds of the heart were clear.

About three weeks afterwards she suffered from a sharp feverish attack, without, however, any indication of chest-affection; her tonsils were much swollen, and her strength was much reduced; she was recovering from this attack, when, on February 2nd, she began to complain of pain in the cardiac region.

On February 3rd, the pulse was 104, respiration 42. The pain in the region of the heart had been relieved by fomentations. A slight but distinct *frottement* was felt over the entire cardiac region, most distinctly at the base, but disappeared after the following day. A double friction-sound was very distinct, whereof the systolic sound was heard to an unusual extent, for an exocardial murmur, beyond the limits of the cardiac region. The patient was very feeble. A blister was ordered, and a mixture of decoction of cinchona with compound tincture and ammonia.

Evidence of fluid effusion in the pericardium presented itself on the following day, February 4th; the cardiac dulness extending completely across the sternum, and in an upward direction to the third cartilage, and at the same time the rubbing sound, though remaining distinct, became systolic only, and resembled more nearly a blowing sound, though retaining a "crumpling" character at the base. Pulse and respiration as before: the pulse very yielding and unsteady, and the action of the heart so tumultuous as to shake the whole left chest. At this time a troublesome vomiting set in, and prevented her taking wine and medicine, so that for the five succeeding days, an occasional dose of morphine, with the application of fomentations, was the only medical treatment employed.

On February 9th, she improved and began to take some solid food, though in small quantity, she also took more readily the wine which had been previously prescribed. The ammonia and bark mixture was resumed, and a morphine pill ordered each night.

Though her state did not occasion the least anxiety, she advanced very slowly. It was not till the thirty-eighth day of the pericarditis (March 11th) that she could leave her bed even for a short time. A mild attack of pleurisy developed itself on the left side, on February 11th, and it was eighteen days before the effusion was removed from the chest.

She suffered considerable pain in the left side, both before and during the attack of pleurisy, and her posture was rendered irksome, between the soreness of the left side, and the breathlessness occasioned by any attempt to lie upon the right. A troublesome cough too, occasioned by great enlargement of the tonsils, distressed her, and required removal of a portion of one tonsil for its relief.

The pericardial effusion began to lessen in four days after its first appearance, and was entirely removed in the course of two days: the action of the heart becoming more tranquil; but nine days afterwards, from some unexplained cause, it reappeared, even exceeding its former limits, and a week elapsed before it began again to retire.

The friction-sound had not ceased to be heard when the patient left (April 4th), but on her visiting the hospital seven weeks afterwards, it could not be distinguished at all, though in a month subsequently some roughness of the first sound was noted at the base.

The sound had continued systolic, and hardly distinguishable from a bellows-sound, excepting by its position (along the left edge of the sternum) and by the circumstance that at one time, a distinct diastolic sound was produced by firm pressure with the stethoscope, at a particular spot corresponding to the fourth cartilage. Adhesion of the pericardium if effected, as was probably the case, was very slow in accomplishment, and was probably never complete.

[To be continued.]

**SPONTANEOUS DECOMPOSITION OF CHLORIDE OF LIME.**  
About three years ago, Dr. Hoffman mentioned the case of a choice specimen of chloride of lime in his laboratory undergoing spontaneous decomposition, and bursting the bottle to pieces. Another instance of this decomposition occurred in Dr. Letheby's laboratory. The specimen of chloride was perfectly dry, and the bottle had not been opened since June last. In making an attempt to loosen the stopper it was projected with great violence. The residual gas was instantly secured by covering the bottle, which was not broken. It was colourless, there was no odour of chlorine, but when tested by a match with spark it was relighted several times—an experimental proof that the result of the decomposition was oxygen. ### PRACTICAL REMARKS UPON THE PREVALENCE AND TREATMENT OF SYPHILIS.

By JEFFERY MARSTON, M.D., Royal Artillery.

So long as the public will not entertain any plan of legislative enactment with the view of controlling the spread of syphilis, it would be futile to dwell upon the importance of sanitary measures directed to the examination and removal of affected women.

In large towns, indeed, it would be difficult to carry out efficiently any measures to this end; but it is not so within the limited areas of smaller garrison towns, particularly abroad. The experience obtained in Belgium and elsewhere of the control and diminution of syphilitic disease by these measures is quite parallel with my own observations. In Malta and Gibraltar, where measures were stringently enforced, there was almost entire immunity from syphilitic disease amid the troops; and when, as in the former station, these sanitary measures were discontinued, disease became so quickly and widely prevalent as to necessitate a recurrence to them.

Looking to the immense amount of disease and want entailed by these disorders, the great expense incurred by the Government from their widely spread prevalence among troops, and the subsequent loss of health and strength, as well as the congenital or inherited diseases to be traced to these causes, it seems wonderful that so little should be done to prevent their spread, and that the desire should be so determined to ignore their existence.

The number of hospitals and means in Great Britain for the treatment of so highly a contagious disease is very small and quite inadequate.

Persons out of the army can form but little idea of the amount of disease and the modifications of health induced by syphilis.

The limits within which any suggestions can be offered are practically narrowed to such as can affect the soldier. Military hospitals—in Britain, at any rate—would be comparatively empty were it not for diseases of this kind. As at present, the liberty of the subject is carried to its furthest extent, and made to press unfairly upon the more steady soldier. In all benefit clubs, it is a recognised custom that no member shall obtain any advantages for diseases of his own producing and within his own control. In the army, it might surely be regarded as a breach of contract when a soldier escapes his duties by his own immoralities. A soldier whilst in hospital with such a disease pays no more than another suffering from one the direct result of the execution of his duties. Moreover, for every day so spent, duties are escaped, which fall upon the other and effective men, upon whom therefore, practically, the burden falls. It often happens, also, that a soldier, by means of such diseases, is enabled to escape some punishment awarded to him at a date prior to the appearance of it. These facts seem to carry with them their own remedies.

It would be Utopian to suppose that we shall be able to eradicate diseases of this nature by any efforts directed to the education and amusement of the soldier. No doubt the practical workers in sanitary science have done much, and much more remains to be done; but we must not forget that diseases resulting from immoralities are common enough among persons as far removed from the soldier, in these respects, as possible. If not so common, obviously, the one class possess means by which they can more easily guard against and escape these evils than can the other.

It is well that those who expect so much from the education and elevation of the soldier, should remember that the life of a soldier is altogether peculiar; *e.g.*, he enters the army as a very young man, and is not an old one when he leaves it. During this period of life the passions are not by any means at their weakest. The life of a soldier is a non-natural one of celibacy. It would be incompatible with the nature of his occupation for the soldier to be married, even were it practicable to find sufficient barrack accommodation. Every one will perceive that such a state of things must entail a good deal of immorality.

The married soldiers, however much they may encumber a regiment upon the march, or in barracks, do not swell the list of occupants of military hospitals and prisons.

A soldier's life contrasts with that of a civilian at the very commencement. The "raw material" of our army is composed, in some part, of men unfitted for occupations requiring steady habits and perseverance—if not worse; and the discipline of the army exerts a great influence in the removal and repression of much of the crime which would otherwise elsewhere occur. The plan of enlistment is but too often a scandal. The system of barrack life is such, that a man is contaminated by the evils around him; it almost necessarily entails a loss of modesty; and individuals obtain that kind of mutual support and sympathy from the conduct of others, to which we can find no parallel in civil life.

*Abortive Treatment.* Although the doctrines hitherto promulgated upon this head require some limitation, it is certainly true that the soft suppurating chancre can be destroyed by caustics.

As obviously we can have no means of diagnosing the exact nature of a sore at early dates, before the appearance of its induration, or the characteristic affection of the inguinal glands, we must not conclude (as is too commonly done) that we have, by an early destruction of the sore, prevented the occurrence of constitutional infection, because no further symptoms follow. We can, pretty certainly, arrest the progress of the soft suppurating form by caustics; and shall certainly do no harm, at least, if it prove to be of the indurating, infecting variety.

The agents which I am in the habit of using for this purpose are—the strong nitric acid, or the potassa cum calce (the latter is very convenient in the form of small sticks). If the former be applied, the pain may be very much alleviated indeed by immediately afterwards pouring a continuous stream of cold water upon the part from some spouted vessel.\*

Should the soft, suppurating sore not be destroyed within a few days of its appearance, the tissues surrounding it imbibe and become infected with the virus; the specific ulceration will then tend to run its course, and it may be five or six weeks, or much longer, before the sore heals.

It may be well, therefore, to use various means to accelerate the healing of a suppurating sore, and such means are sometimes absolutely necessary. So long as the sore has the specific characters of ulcerating deeply, with clearly defined vertical edges, it is right to continue the use of some mild caustic, such as solution of nitrate of silver. When granulations spring up, and the base appears healthy, it matters little what applications be used, provided the part be kept scrupulously clean.

The ulcer may assume the characters and appearances of similar lesions elsewhere situated; *e.g.*, it may be indolent, irritable, or inflamed, or, by granulating too redundantly, impede the cicatrization. Such symptoms are to be met by the same measures as would ordinarily be used.

If the chancres threaten sloughing, it is best to dry the parts and apply nitric acid; afterwards using a lotion of potassio-tartrate of iron. With a solution of that salt applied to the sore, and the administration of the same drug internally, the phagedenic action will almost always alter its character.

Sometimes a large amount of inflammation, with great pain, attends the local progress of the disease. In such cases, the administration of morphia in liquor ammoniæ acetatis is highly beneficial.

That peculiar form of destructive ulceration which gives rise to the serpiginous sore, may not only attack a chancre or bubo, but the seats of lesions of consecutive syphilis. In sores, the subject of this complication, there is a tendency to the destruction of the neighbouring tissue in the form of segments of circles. It is a molecular death of the part, and is preceded by an inflamed, glazed, shining appearance of the surface. This is often very difficult of cure. Sometimes the application of calomel vapour to the part is very beneficial; particularly if the bichloride of mercury in tincture of cinchona be given at the same time, with the soap and opium pill at bedtime. A little watching upon our parts will soon determine whether this plan is likely to prove useful. The administration of the potassio-tartrate of iron internally, and the application of a lotion of the same salt to the affected part, sometimes answers very well.

The great thing, however (as far as local measures are concerned), is to excite an artificial and more healthy inflammatory process around the periphery of such sores. The following plan is a very good one:—A thin layer of Fell's paste (chloride of zinc paste) is to be spread on the unhealthy edge, in such a way as not only to destroy the affected, but a narrow rim of the nearest healthy tissue also. Attention to cleanliness, good air, and hygiene, are of primary importance in these cases.

Of the buboes which attend and accompany these chancres, two varieties may be mentioned. The progress of the first we can hope to arrest, while that of the latter will surely go on.

*First.* An inflammation of the lymphatics,—such as often occurs after abrasions or wounds of other parts,—may arise. The nearest inguinal gland may enlarge, and the textures seated upon it inflame, without there being any specific material in the gland-tissue itself. If an abscess form, it is a simple abscess, and the ulcerated surface does not become a chancre, affording inoculable discharge.

*Second.* When lymphatic absorption occurs, there is a transmission and lodgement of a chancreous virus in the part. An abscess will then ensue, and the resulting ulcer will, oftentimes, be but a repetition of the chancreous process, and to be treated, therefore, in a similar manner to the chancre.

When we have no means of deciding to which division the symptoms in the lymphatics are to be referred, it is well to try—by a few leeches, perfect rest, hot or cold applications, pressure, and the application of vesicants—to prevent suppuration. Of the latter, the best are—the vesicant action by a strong solution of iodine, or painting the integument with a strong solution of nitrate of silver, dissolved with the aid of a little nitric acid, as suggested by Mr. Henry Thompson. As soon as the effect of these remedies has subsided, pressure may be employed if the parts are still enlarged.

Should these plans fail in discussing the tumour, it is better to allow the patient to get up and walk about in the air.

Suppuration having set in, shall we open by multiple and small incisions, or by a depending one, involving the whole length of the swelling? The former course—with or without the use of stimulating injections—has proved very uncertain in its results; a free opening is generally to be preferred. The wound may then be dressed with strips of lint, from the bottom.

\* The application of nitrate of silver for this purpose is useless, from its limited action and deficiency of penetration.

If the integument be thin and undermined, the action indolent, and the skin of a dull red colour, opening the abscess by means of a liberal application of potassa fusa will be found to expedite considerably the subsequent healing.

When the abscess has been laid open, it will be often found that a large indolently inflamed gland appears at the bottom. Between this and the apposed textures no union will generally ensue, and nothing is more common than to be able to pass a probe around the circumference of such gland. Matter is apt to lodge in these intervals, inflammation and burrowing to ensue, with the formation of sinuses.

Nothing can be more troublesome to cure than these buboes; and by far the shortest course is to destroy the gland by caustics, or to put the patient under chloroform, incise the gland, and detach it with the handle of the knife or fingers, subsequently stuffing the wound with lint.

As the last may appear a severe plan of treatment, it may be well to try first the effect of repeated applications of nitrate of silver or the red oxide of mercury, by which the gland-tissue is gradually destroyed, and contraction of the walls of the abscess sometimes ensues.

Sinuses, here as elsewhere, must be laid open; for it is rarely that these heal by the injection of astringent and stimulating fluids. Of course, however, the effect of these can be tried before proceeding to the incisions.

When a sinus runs perpendicularly downwards—i.e., at right angles to the surface of the body—it cannot be laid open. An enlarged and inflamed gland will be found occupying the base of the sinus, and preventing its healing. By applying caustic to this, and stuffing the part with lint, it may be generally be made to heal from below. So soon as there is a healthy granulating foundation, the sinus will begin to be filled up. If the process become chronic, it is a good plan to pass a narrow bistoury to the bottom, and incise the walls of the sinus, applying pressure afterwards.

During the whole treatment, the patient should live well, take as much air and exercise as he well can, and steel with tonics are generally indicated.

Of the treatment of the infecting sore, I may at once state that, do what we may, constitutional symptoms will generally follow. I have treated cases with mercury until not a trace of induration has remained in the cicatrix, and yet secondary symptoms have appeared. Looking back upon the records obtained from numerous observations, I am led to conclude that mercury will remove an induration more speedily than any other medicine; that the interval between the appearance of the primary and secondary phenomena is more protracted than when mercury has not been used; that the secondary symptoms, when they appear, are not so marked or so severe, but that the syphilitic cachexia and loss of health may be as marked as if no mercurial treatment had been pursued.

Some of the worst cases are those in which the system becomes speedily affected with mercury, and a rapid ulcerative action sets in about the induration of the chancre. A rapid effect upon the system by mercury seems almost invariably to act injuriously; whether such result from the idiosyncrasy of the patient, or the object of the surgeon.

In many cases, the constitutional symptoms will be relatively slight, and the progress of the disease does not pass the secondary stage, but, in spite of relapses, tends to wear itself out; in others, the symptoms appear to increase rather than diminish in intensity as the evolution of the disease progresses. Diday makes the very practical division of the mild and severe, and modifies, to a great extent, the treatment pursued, by the recognition of these two types.

In the employment of mercury for the treatment of

syphilis, I do not think that sufficient attention is given to the following.

1. *Hygiene.* The patient should be warmly clad; live upon a good but plain diet; take plenty of exercise in the open air; use occasionally warm baths; and avoid stimulants, unless specially indicated.

2. It is neither necessary nor desirable to depress the system for the cure of syphilis. The disease in itself tends directly to induce a chloro-anæmic state; and it too often happens that the sufferers from it are the subjects of some debilitating conditions—congenital or acquired. In all cases, it is essential to elevate the general health to a normal standard; and we should neglect no means so to modify our treatment as to meet the exigencies of the case. As in other diseases, individual cases will almost always present a physiognomy of their own. Not only is there no reason against, but every reason for giving steel, quinine, vegetable bitters, or cod-liver oil, as circumstances require; at the same time that we apply a specific remedy.

Believing, as I do, that there is no remedy equal to mercury for the treatment of this disease, I cannot avoid perceiving that in primary affections its administration rarely, if ever, prevents the occurrence of constitutional symptoms; while, for the secondary lesions, it will be found that relapses and slow recovery are the rule, and a rapid return to health the exception.

In the treatment of the primary disease, I am guided by two considerations—1. The history of a previous attack of true syphilis; 2. The condition and indolence of the sores.\* If the sore be but slightly indurated; if it do not prove indolent, but can be healed by local remedies, I do not think it right to anticipate symptoms, which after all may not occur, by a remedy of doubtful efficacy, as a preventive to their appearance.

As many of the sores are mixed, and not so typical as described in books, the diagnosis is obviously not quite certain.

Powdered calomel is one of the best local applications to the indurated sore.

When sloughing, gangrene, or rapid ulceration appear in the chancre, mercury is either not to be given, or immediately withdrawn.

With regard to the various modes of treating primary syphilis by iodide of potassium, etc., I have not been able to assure myself of their possessing any influence.

Almost all primary sores will heal without treatment in time; but, when much induration exists, non-specific remedies fail to affect this, and the constitutional symptoms appear, as regularly and certainly, as if no treatment had been pursued.

For the secondary symptoms—with the exception of the pustular, rupitic, and ecchymatous forms of syphilide, or those accompanying cachectic states of the system—mercury, in some form or other, is the best remedy.

The course I pursue is—to use the mercurial vapour-bath, or mercurial inunction; allowing the patient steel and a good meat diet, if his strength appears impaired by the treatment. I invariably attempt to affect the system as slowly as possible, and to remit for a time the use of the remedy as soon as that effect has been attained.

Ricord advises that mercurials should not only be used so long as any symptoms are apparent, but that the treatment should be continued and sustained for long periods afterwards. With all deference to so great an authority, I am not sure that the practice indicated is a good one, even if patients could be found to submit

\* Supposing the patient to have suffered from a constitutional syphilis, the infecting sore will be much modified in its characters, and will rarely require mercury to heal it. Unless, therefore, there are some other reasons present for its administration, it is unnecessary.

to it. I have myself tried his plan, and, I fear, to the disadvantage of the patient.

What I conceive to be preferable is, to follow up the mercurials, so soon as the symptoms for which they have been given have fairly disappeared, by a course of steel and other remedies. In three cases (after the use of mercury, where the health seemed impaired by the remedy, and although no fresh symptoms had appeared, the cutaneous affections could not be said to be quite cured), I have given podophyllin in small doses (1-6th gr.), with extract of belladonna, with great advantage. The complexion improved very markedly under the use of this remedy.

Without having any statistical evidence whereon to ground my belief, I may say that symptoms referable to internal syphilis—such as cerebral, osseous, and glandular diseases—are apt to appear when a mercurial treatment has been sustained for a long period.

What I particularly remarked also, in some cases, was a cachectic aspect, and a liability to chronic rheumatismal pains, without cutaneous manifestations of syphilis, where a mercurial plan of treatment had been too persistently pursued. Among these rheumatoid affections, I would enumerate sciatica, and inflammations of the fibrous fasciæ covering tendons, bones, and cartilages.

The exhibition of mercury by the calomel vapour bath is excellent. It is not liable to affect the digestion, and it leaves room for the exhibition of any other remedies that may be required. It is, moreover, mild, slow, and equable in its action; so that it is safer than other plans, inasmuch as we have no means of telling beforehand what effect the remedy will have upon the system. Sometimes, from these very causes, it seemed to be inadequate. Every one must have remarked the seeming antagonism between the two states of system—that engendered by syphilis, and that by mercury. A patient will, perhaps, be easily affected by the mineral exhibited during the primary, and very difficultly so during the later stages of the disease. In cases of relapsing secondaries, the system is very tolerant of the drug, and but little amenable to its action. Hence, often, mercurial inunction will cure more speedily than the calomel vapour-bath. A very good plan is to rub some mercurial ointment into the thighs, and direct the patient to wear the same drawers for ten days or a fortnight, taking a tepid bath occasionally at night.

Should the patient's system be early affected by mercury, while the symptoms are not benefited, I give chlorate of potash in compound tincture of cinchona at the same time.

Of the internal preparations of mercury, I prefer the bichloride, in compound tincture of cinchona or in tincture of sesquichloride of iron; or the iodide of mercury in half-grain doses, with iodide of potassium or syrup of the iodide of iron.

Frequently, in strumous subjects, I find it useful to give the bichloride of mercury combined with cod-liver oil, which is easily done by first dissolving the bichloride in ether, before adding it to the oil. In some of the more intractable forms of syphilitic squama, a combination of liquor arsenicalis, solution of bichloride of mercury, and tincture of sesquichloride of iron, will be found very useful.

In syphilitic diseases of the skin generally, Mr. Starlin's advice to avoid the use of soap in ablution is well worth bearing in mind. The soap appears to irritate and inflame the parts occupied by an exanthem, and to protract the cure of the disease.

For the symptoms denominated tertiary, it is well always to try the effect of iodides of potassium, iron, etc.; for it is in this stage of the disorder that these remedies appear so useful. Should they, however, prove inefficacious, recourse may be had to mercurial treatment, by means of the calomel vapour-bath.

In some of the syphilitic diseases of the interior of the cranium, giving rise to extreme pain and symptoms indicative of cerebral irritation or inflammation, iodide of potassium, in large doses, appears to act with rapid benefit; while in others it as completely fails. When it does so, it is a good plan to shave some part of the head, blister the scalp, and dress the blistered surface with mercurial ointment; at the same time continuing the use of the iodide of potassium.

In the treatment of the external manifestations of syphilis, much benefit may be derived from local treatment. It often happens that a patient is cured of a cutaneous syphilide, in so far that no fresh spots appear, yet the older sores fail quite to disappear. In such cases, local treatment succeeds admirably. To indicate some of the symptoms and states benefited by local measures, I shall enumerate a few illustrations.

Raised papules (cutaneous and mucous) may remain indolent. The application of an ointment, composed of oxide of zinc, calomel, and simple cerate, will hasten their absorption.

The eruptions such as lichen, acne and herpes, will also be much benefited by the application of oxide of zinc lotion, or ointment; and if, as often happens in soldiers who have served in warm climates, these cutaneous diseases be mixed with prurigo and urticaria, the diacetate of lead lotion will equally expedite their cure.

Some of the vesiculo-crustaceous looking spots will, equally, cease to reappear if the affected parts be first painted for a few days with a solution of nitrate of silver (gr. x—xx to ʒi), and the oxide of zinc lotion applied afterwards.

Tar ointment, or the alcoholic solution of tar, is an excellent application to most of the dry forms of cutaneous syphilide, and to chronic eczema of the extremities.

Indolent glandular swellings, in a similar way, will gradually disappear under the use of strong solutions of iodine.

The superficial form of ulceration attending the pustules of ecthyma will likewise be much benefited by the occasional use of solutions of nitrate of silver or sulphate of copper. The deeper forms of ulceration attending the appearance of ecthyma as a tertiary phenomenon will hardly get well without the application of caustics and local stimulants.

The fissured condition of the palms in psoriasis palmaris will be much improved by the use of glycerine.

Whenever any of the ulcerated bases of syphilitic sores threaten sloughing, lotions of potassio-tartrate of iron will generally improve their aspect.

It must not be forgotten, that a papular form of eruption may appear after the use of iodide of potassium, and be mingled with the other cutaneous affections, as I have more than once observed; this will disappear upon the discontinuance of that remedy.

In all cases of cutaneous syphilide, an occasional warm bath will have a beneficial effect.

In the secondary syphilitic sores and fissures about the lips and buccal membrane, the occasional use of nitrate of silver and lotions of chlorate of potass will prove very effective.

Syphilitic onychia is a very troublesome affection, and, in addition to the use of mercury, will require careful local treatment. It varies much in degree and severity. The milder cases are excited by an ingrowing nail, the top of which has, probably, been torn down to its bed by the patient. The overlapping fold of skin then commences to inflame and ulcerate. The plan of treatment is, to remove the pressure by inserting some cotton wool in the interval between the fold of skin and the nail, at the same time that we harden the integument by lotions of nitrate of silver, and wait the growth of the nail beyond the bed upon which it rests. In other cases (particularly in the true syphilitic onychia, where the ulcer-

ation commences as a dark spot at the root of the nail, it is best to scrape the nail as thin as possible, and repeatedly apply the solid nitrate of silver, as well as a lotion of the same salt, to the parts, by which the death of the nail is procured, and, as it rises from its bed, it can be separated. In some it will be necessary to enucleate the nail, and then to treat the ulcerated surface.

*Syphilitic Iritis.* In the treatment of this affection, mercury and the application of atropine are the ordinary means used.

The mercury need not be given in large doses; and there is no reason against employing such other remedies as the state of the patient may indicate. It is well to drop the solution of atropine into the eye every six hours, or sufficiently frequently to maintain a dilated condition of the iris.

In some cases, neither mercurials, iodide of potassium, nor turpentine, appear to exert any effect. The iritis, instead of yielding, appears to advance. Some cases are, probably, of complicated nature—a mixture of the rheumatic with the syphilitic form of the disease.

I have seen an iritis commence in one eye of a patient who was affected with mercury for an iritis of the other eye.

In these cases there is not only a good deal of circum-orbital pain, with photophobia and lacrymation, but the anterior chamber becomes clouded; the iris with the periphery of the cornea yield, so that the latter appears to rise abruptly out of the sclerotic, although the cornea, as a whole, is less convex than normal; and the eyeball feels a trifle more tense and firm than that of the healthy organ.

In addition to the synechia, and recurrence of iritis from this very cause, there is a well grounded fear that the eyesight may remain impaired. In such cases nothing answers better than a division of the ciliary muscle and evacuation of the aqueous, by Mr. Hancock's operation.

In two cases in which I pursued this course, great and rapid improvement ensued.

The operation is so slight, and so easily performed, that there is little or nothing to fear from it in these respects. When it is considered that the ciliary muscle is the point at which the sclerotic, cornea and iris meet, and that any effusion behind the iris must tell directly upon this, the most unyielding part of the eye, we cannot be surprised at the beneficial results ensuing from its division, and the establishment of an opening between the anterior and posterior chambers.

Now that I am upon the subject of iritis, I may remark that there is a variety of ophthalmia occasionally following gonorrhœa, allied, in its symptoms and appearances, to rheumatic iritis; indeed, it is a form of gonorrhœal rheumatic inflammation. This disease is very easily mistaken for syphilitic iritis; but it differs from it in not having the minute beads or nodules of lymph deposited upon the iris, which are so common in the syphilitic disease. The sclerotic is always affected; the conjunctiva generally so; and the margin of the cornea looks dull, preventing the perfect view of the iris. The pupil is contracted, as in syphilitic disease, and yields difficultly to the action of atropine, but synechia is not a common result. The disease is more chronic, painful, and difficult of cure than the syphilitic form; photophobia and lacrymation are also more marked phenomena.

Rollet has well described this sequela of gonorrhœa. I have given the symptoms as I have observed them; and the subject has been introduced here upon account of this form of disease being very commonly, but erroneously, referred to a syphilitic origin.

In conclusion, I must reiterate, what I have already implied, that any treatment of syphilis, particularly in its constitutional phases, will be materially assisted by a strict attention to hygiene. The patient cannot take

too much air, nor live too plainly, nor can we endeavour too much to invigorate his system. In military hospitals this cannot be done, unfortunately, to anything like the required extent. Air and exercise cannot be obtained; and the patient, after a monotonous confinement within the wards of an hospital, but too frequently plunges into dissipation as soon as he leaves it.

## ON UTERINE FLUXES, THEIR CAUSE AND CONSEQUENCES.

By W. E. C. Nourse, F.R.C.S., Brighton.

UTERINE and vaginal fluxes mainly originate in conditions of local vascular fulness and activity, dependent on the anatomy of the uterine blood-vessels, or on the vascular determinations consequent on the various physiological conditions of the womb. In this, they differ from the bowel-flux and lung-flux, the two other great classes of disorder in which discharge from the body is an essential feature, and which are more under epidemic influences. The fluxes from the utero-vaginal tract may be enumerated as:—1. *Hæmorrhagic discharges* (excluding those of pregnancy or parturition); 2. *Menstrual discharges*—menorrhagia and dysmenorrhœa; and 3. *Altered discharges*—leucorrhœa.

I. A lady was attacked with violent flooding four weeks after a miscarriage. Here the recurrence of the monthly determination was the principal cause; the uterine muscular fibres not being in the same state of development as they possess four weeks after child-birth, when they have power to prevent by compression any such occurrence. But, non-completion of the requisite changes after the expulsion of the contents of the uterus, is also to be taken into account. Uterine disorder is often noticed after the birth of a dead child. A case of this sort is recorded, in which peculiar uterine conditions were present, coupled with typhoid fever. The following is somewhat similar. A lady was confined with a dead child; after which menstruation was profuse, and with clots; and in four months she was attacked with low fever, accompanied by intense hysteria. Excessive and painful menstruation continued for some time; but at length was replaced by leucorrhœa. Two years later, she was suffering from symptoms treated as ulceration of the os uteri, with the speculum and caustic, but which were in reality, merely due to relaxation of the vagina, permitting the uterus to fall a little from its place. Cure was speedily effected by means restoring the tone of the vagina. This patient had suffered from hepatic symptoms. In another case there was congestion of the uterus after the birth of a dead child. In another, irregular, painful, and excessive menstruation, with uterine leucorrhœa, following the birth of several dead children. Circumstances pointed to previous uterine derangement. In these cases, the death of the fœtus is probably caused by previous uterine disorder, which becomes more prominent after the birth, and thus is noticed as following the birth of a dead child.

II. In other cases, menorrhagia was associated with plethora; with hysteria; with debility and want of vital power; with lactation; alternating with leucorrhœa, the vagina relaxed, and the womb low down; and especially with hepatic derangement, and with habitual drunkenness. Disordered liver, however caused, is frequently found to accompany increased, difficult, or painful menstruation; the obstructed portal circulation favouring a tendency to pelvic congestion.

III. Leucorrhœa frequently alternates with, or succeeds and replaces dysmenorrhœa and menorrhagia. A lady, subject to frequent attacks of painful congestion of the liver, was also a great sufferer from dysmenorrhœa. Some years after, leucorrhœa alternated with the dysmenorrhœa; and ultimately, there were symptoms of

dropping of the womb, with enlargement and congestion of the os uteri, from relaxation of the vagina. Another lady, subject to hepatic derangement, suffered from excessive and painful menstruation. Miscarriage was caused; and after a time, leucorrhœa came on. In these disorders, the uterus itself remains free from any structural alteration. But a common sequel of long continued leucorrhœa is, relaxation and weakening of the mucous membrane of the vagina. Former disturbed menstrual conditions may have ceased; the menses themselves, from one cause or other, may have ceased; the leucorrhœa accompanying former menstrual disturbance may remain, or again, it too may have ceased; while the consequences of these successive occurrences, which have very likely been forgotten, the relaxation of the vaginal mucous membrane, may be giving rise to a number of structural alterations. The commonest of these is, partial descent of the uterus, the os uteri being lower than natural, and often resting on the floor of the vagina. This condition, if unrelieved, may last long, and cause much distress. If it be suffered to continue, another change takes place. The os uteri thickens and enlarges, or may even ulcerate. Other well known effects of relaxation of the vaginal mucous membrane may be, either vaginal rectocele, vaginal cystocele, or prolapsus uteri, diseases which may last for years, long after the uterine fluxes which have preceded them have ceased.

Thus the sequence of events is: 1. Menorrhagia or dysmenorrhœa, due to vascular fulness about the uterus, often connected with obstructed portal circulation; 2. leucorrhœa; 3. Relaxation of the vagina, permitting the womb to fall a little from its place; 4. Consequent enlargement of the os uteri, perhaps with ulceration; 5. Some kind of prolapsus.

### BATH AND BRISTOL BRANCH.

#### CASE OF MONSTROUS BIRTH.

By JOSEPH HINTON, M.R.C.S., Hinton, near Bath.

[Read November 27th, 1862.]

THE mere fact of the uterine contents being monstrous in form may not in any way interfere with the parturient efforts of the organ, and the delivery may prove perfectly natural, albeit the said contents may have faint resemblance to "the human form divine"; whilst, again, with scarcely any extreme deviation, the monstrosity may complicate the delivery, and render our diagnosis exceedingly difficult. To this latter category my case belongs.

A few weeks ago, I received an urgent message to attend a woman, who was in labour before she anticipated. From the messenger I could gather nothing as to the nature of the case, and nothing very satisfactory as to the duration of the labour. On this latter point, I have since received very conflicting accounts; the current report being that the woman had been several days in labour; that some six-and-thirty hours before my arrival, the pains had been so violent, that the completion of the labour appeared imminent; but that soon, and without any reason, these pains died away wholly, and she had scarcely experienced any since. The midwife declared that she had sent off immediately on discovering that something was coming down, which she could not understand. The patient was a young and apparently healthy primipara. Her condition was not the most satisfactory. She was cold and shivery, often drowsy; her pulse small and feeble; in fact, she was decidedly prostrated. She did not consider herself more than seven months advanced. On examination, I found a mass, of the size of a cricket-ball, outside the vagina; it

gave somewhat the sensation of the placenta but smoother. Unable to arrive at any conclusion as to its nature by the touch, I exposed and carefully examined it, but for some minutes I was equally staggered.

Its odour and appearance resembled that of strangulated intestine in a sloughing condition. The closer the examination, the more convinced was I that the mass was intestinal; at last, I fancied I detected something that might pass muster as a diminutive appendix vermiformis. A vaginal examination was made with difficulty. I traced the mass within what I believed to be the posterior edge of the os uteri; but was unable to detect any other presenting portion. I was led to diagnose total deficiency of the abdominal walls in the fœtus, and that this presenting mass was the fœtal intestines. With much difficulty, I succeeded in reaching a knee, and bringing it down; the foot was very broad and flat, with scarcely any great toe; the cuticle separated very easily, although the patient considered she had felt the child in the morning. The other foot was then brought down; it resembled its fellow. The nates and abdomen, such as it was, were then brought to view. To the inexpressible horror of the midwife, the former boasted a very respectable tail about two inches long, and a quarter of an inch in diameter; it was devoid of hair.

In endeavouring to deliver the remainder of the fœtus, the spine gave way. I then brought down both arms. The third finger on the right hand was a stump. I used all the force I dared with the arms unsuccessfully; the head was not in the pelvis, the neck being much stretched; the abdomen was still large. I therefore left the patient quiet and she fell asleep, whilst my instruments were sent for. Whether during this interval any portion of a large hydrocephalic head had so given way, as to allow the escape of a portion of the fluid, I cannot say; but on introducing my fingers to guide the blunt hook, a large quantity of serum escaped, and possibly an attempt at delivery might have been perfectly successful. I decided, however, on passing the hook; and, fixing it in a portion of bone I could detect, which proved to be the left orbit, I drew out with tolerable ease an enormously elongated head, like a thickened bladder, with the cranial bones hanging loosely in the interior. The placenta was soon expelled; it was large but healthy, except in the funis. The child was a male.

The head was exceedingly large; the body was not larger than that of a seven months fœtus; the nails were unformed; the features were most revolting; two holes represented the nose, whilst, extending into this feature, was a very wide hare-lip, the lip itself being scarcely visible; the palate also was deeply cleft. The cranial bones appeared loose within a very thickened scalp. Within this there was still a quantity of fluid; there was also a small cerebral mass. The spinal column was much distorted, being bent with the bow part forwards. The abdominal parietes were wholly deficient; the left kidney appeared almost in its normal position; the right was amongst the convolutions of intestine; so also was the liver. I could not make out exactly how the funis was attached, as it had suffered from the general condition, and had given way in the delivery. Some drops of meconium oozed from the anus.

When I placed the monster in position for taking a rapid sketch, I was struck with the resemblance in face to a man whom I used often to see in Bath, who walked by the aid of two sticks, on the balls of his toes, and has, I think, hare-lip, etc. At any rate the expression was very similar, and the same impression was conveyed to the mind of the midwife. However, the patient, when questioned, denied firmly having experienced any fright at any time during the pregnancy. She allowed that she knew this man, and that, about five months ago, he pointedly came across the street to her to beg.

Here, the patient, if her statement can be believed, and there appears no reason for doubt, was unaware of

any effect having been produced on her, nor was the fact of her having seen this individual, elicited except on cross-examination. We very often meet with the reverse; frights sustained, horrid phantoms and realities witnessed, yet the fœtus is proof against them all.

As this man is a Bath character, I was anxious to mention the case at one of our Bath meetings, hoping some of our associates might know more of the individual, and be able to tell us whether he enjoys the distinguishing mark of a tail, which in these days of disputation, might prove a valuable connecting link to those, who contend that men are only monkeys of a wiser growth.

If he be thus gifted, it is a peculiar coincidence that it should be stamped on the fœtus, without the cognisance in any way, as we must presume, of the mother.

## Reviews and Notices.

LECTURES ON SYPHILITIC AND VACCINO-SYPHILITIC INOCULATIONS: their Prevention, Diagnosis, and Treatment. Illustrated by Coloured Plates. By HENRY LEE, F.R.C.S., Hon. Fellow of King's College, London; etc. Second Edition. Pp. 335. London: 1863.

SINCE the first edition of these *Lectures* appeared in 1854, Mr. LEE has zealously and ably availed himself of the opportunities at his disposal for observing the phenomena of syphilis. The conclusions at which he has arrived he has from time to time made known through the medium of the medical societies and the professional press; and he has now done good service in collecting into one volume his opinions on *Syphilitic and Vaccino-Syphilitic Inoculations*, on which subjects he has acquired for himself the right to be listened to as an authority.

The volume before us consists, besides a preface and introduction, of sixteen lectures under the following heads: 1. The Suppurating Syphilitic Sore; 2. Syphilitic Infection; 3. Syphilisation (so-called); 4. Syphilitic Inoculation in Animals; Lymphatic Absorption; 5. Destructive Syphilitic Inflammation; 6. Transmission of Syphilis by Vaccination; 7. and 8. Vaccino-Syphilitic Inoculation; 9. Twofold Inoculation; 10. Inoculation with the Blood of Syphilitic Patients; 11. Syphilitic Inoculation Modified by the Hereditary Transmission of Disease; 12. Syphilitic Inoculation Modified by Previous Disease; 13. Transmission of Secondary Syphilis; 14. Constitutional Syphilis; 15. Secondary Syphilis, continued; Tertiary Syphilis; 16. The Calomel Vapour-Bath.

Until within a recent period, writers on syphilis have sought to determine the number of poisons producing the morbid actions commonly classed as venereal. Some have recognised but one poison as producing all the syphilitic affections, including gonorrhœa; others distinguish between syphilis and gonorrhœa; while a third class, in addition to this distinction, separates the syphilis which infects the constitution from that which does not. Mr. Lee, however, at the outset expresses his object not to be to engage in speculations as to the number of poisons, regarding which demonstration is difficult and the results often varied and contradictory, but rather to study the modes of action which follow impure contact—"the morbid processes to which the contact of syphilitic matter gives rise, the circumstances under which these diseased actions de-

velop themselves, and the results which they respectively produce."

It is in this way, by the accurate observation of facts, that satisfactory results are to be arrived at. For the several forms of morbid processes observed are each always the same under the same conditions; while theories about the number of different poisons may vary constantly. By describing the morbid processes as they are observed in nature, many of the apparent difficulties which have long surrounded the subject of syphilis are removed, and many apparent contradictions are explained. It was on this plan—observation—that Hunter worked; and it seems that now his labours and writings on syphilis are, for the first time in the present century, assuming their true position and receiving their proper appreciation.

The forms of syphilitic action described by Mr. Lee are two; viz., that which produces the local suppurating sore; and that which infects a patient's system. Either of these may be complicated by lymphatic absorption and by mortification; so that four distinct processes may follow syphilitic inoculation.

"1. The inoculated part may become affected with the 'adhesive form of inflammation,' in which lymph is poured out either in the substance or on the surface of the part.

"2. The absorbents may assume an active share in the morbid process, taking up some of the infected parts, and with them portions of the syphilitic poison. This process will be called 'lymphatic absorption.'

"3. The inoculated part may, within a few days of the application of the poison, be affected with suppurative inflammation.

"4. The morbid action may terminate in mortification. Of this there are two practical subdivisions:—(a.) Death of the whole infected part, which is then thrown off as a slough; (b.) Dissolution and death of a part only of the contaminated structure, leaving a part still infected." (Pp. 3, 4.)

These four kinds of morbid processes were described by Mr. Lee in the *ASSOCIATION MEDICAL JOURNAL* as long ago as 1854.

The subject of lymphatic absorption in its relation to syphilitic infection has been very carefully examined by Mr. Lee. It was asserted by Hunter, that venereal matter is taken up by lymphatic vessels and carried by them into the general circulation; and this theory has been generally received as correct until lately. Recent researches, however, in which Mr. Lee has taken an active part, have shown that in no case can the poison be traced beyond the first set of lymphatic glands. The absorbents convey the poison up to this point, both from the suppurative and from the adhesive or indurated sore; and in each case the peculiar local action is manifested in the parts traversed by the lymphatics and in the glands first in order; but, beyond this point, "no further effect is produced upon the lymphatic vessels. The fluids which they contain are bland and harmless, and afford no indication of containing any poisonous or irritating ingredients." Virchow holds a similar opinion with regard to the supposed transmission of pus and other matters, such as the substances used in tattooing, through the first set of glands beyond the point of absorption—a transmission which he denies ever to take place.

Mr. Lee lays much stress on the *mode of origin*

of syphilitic affections; holding that the action which accompanies the first appearance of the disease will indicate, in uncomplicated cases, whether the patient's system will or will not be infected. The suppurating sore, whether produced by lymphatic absorption or by artificial inoculation, is diagnostic of the pustulous or non-infecting variety of the disease, while the adhesive or indurated sore gives rise to constitutional symptoms.

An important means of diagnosis between the non-infecting and the infecting sore lies in the reinoculation of the secretion. This theory was first announced in 1855 by M. Clerc.

"In 1855, M. Clerc announced the doctrine, that the secretion from infecting sores could not be inoculated—a theory which corresponded with, and might have been deduced from Ricord's dogma, that a person can have syphilis once only. As the indurated sore was allowed to be the necessary precursor of constitutional syphilis, and as syphilis was supposed always to follow an indurated sore, it followed that, when once the constitutional affection was established, the patient's system in which it was so established would no longer be capable of being reinoculated so as to produce again the same disease." (P. 27.)

The merit, however, of proving this point by direct experiment is due to Mr. Lee, who, in 1856, published the results of his observations in the *British and Foreign Medico-Chirurgical Review*. These observations, which have been confirmed by those of M. Fournier (published in 1858), and by the more recent observations of M. Rollet, have established that a means of diagnosis between the non-infecting and the infecting sores lies in the fact that the former yields a secretion which is "auto-inoculable"—that is, capable of producing a specific pustule when inoculated on the patient; while, "if a disease which we believe to be primary syphilis yields a secretion which is not auto-inoculable, then the evidence is against the local character of the affection, and indicates a constitutional mode of treatment." The results of experiments on this point are found by Mr. Lee to be very uniform; and the apparent exceptions which have occurred in his own observations and in those of M. Fournier and Rollet, he ascribes to the circumstance, that in these instances a twofold inoculation had taken place, and produced the local suppurative sore as well as the infecting chancre.

The most interesting parts of the book are those which refer to twofold inoculation, and to the inoculation of the blood of syphilitic patients.

In speaking of twofold inoculation, Mr. Lee argues that this phenomenon may occur under several circumstances, when the products of different diseased actions are brought into contact with the same part of a fresh patient. Thus, gonorrhœa and a suppurating sore, or a suppurating and an infecting sore, or gonorrhœa and an infecting sore, may act simultaneously; or the effects of any of these may be again complicated and masked by the introduction of decomposing fluids. But the most important subject in connection with twofold inoculation, is the transmission of syphilis by vaccination. Regarding this, he shows that the experiments of Viennois, and the startling series of facts recently observed at Rivalta, as well as other observations, demonstrate the possibility of communicating syphilis, whether from primarily or from secondarily infected patients,

by vaccination. This is contrary to the almost universal belief which prevailed a very few years ago, and which is still held by many, that syphilis cannot be communicated in this way. But does this furnish an argument against the practice of vaccination? Certainly not. It merely enforces on our consideration a lesson which has been long known, but which requires occasional repetition—to use proper care in the performance of the operation.

"In practice, four very simple rules would appear to be sufficient to ensure safe vaccination:—

- "1. To use a clean lancet upon each occasion.
- "2. To take the lymph not later than the eighth day from the vesicle of the vaccinifer.
- "3. To take the lymph only, and not to allow blood or other secretions to be mixed with it.
- "4. To obtain the lymph from a healthy subject." (Pp. 178-9.)

The third of these rules is an important one, and forms the text of the tenth lecture. Viennois found in his experiments that syphilis was not communicated unless the vaccine lymph were mixed with blood; and, in the Rivalta epidemic, it is averred that blood issued from the vesicles of the child Chiabrera—the first vaccinifer, who infected the others—during the vaccination, and that the lancet used was impregnated with blood during the operation. The inoculability of the blood of syphilitic patients so as to produce a disease on the inoculated point has been further established by several other experiments, especially those of an Italian physician, Dr. Pelizzari.

Closely connected with this subject is that of the inoculation of the secretions of syphilitic patients, which is treated of by Mr. Lee in his thirteenth lecture. He there shows how many cases which have perplexed Hunter and other surgeons are explicable on the ground of the infection being communicated to a healthy person by the secretions of a patient affected with secondary symptoms, or even by the ordinary secretions of a syphilitic body, when derived from a part in a state of increased action or inflammation. He refers to some interesting cases noticed by Hunter in which syphilitic symptoms were developed after the transplantation of teeth into healthy individuals. Although the cases were believed to be syphilitic and treated as such, it seems to have been a very general belief that the disease could not be communicated in this way; but, calling to mind the results of Hunter's well known experiments on the transplantation of parts, and the demonstration, in one of the previous lectures, that syphilis may be communicated by the blood of an infected person, Mr. Lee argues that

"If the tooth of an infected person be transplanted into the mouth of a person who has never before had the disease, the minute quantity of blood which it contains may be sufficient to infect the healthy person; and it is quite clear that simply wiping the outside of the tooth would not prevent such an occurrence."

Some have supposed, that wiping the tooth before insertion would prevent infection.

Having thus given a sketch of some of the leading points in Mr. Lee's work, we must conclude by commending it to the favourable notice of our readers, as the result of much accurate observation, diligent study, and careful reasoning, on the part of the author.

# British Medical Journal.

SATURDAY, FEBRUARY 21st, 1863.

## THE TITLE OF DOCTOR.

THE "Doctor" and "M.D." title, as assumed by non-diplomatized Licentiates of Royal Colleges of Physicians, is still, as our correspondence will amply show, a disturbing subject of discussion. It is not surprising that there should have been much discussion, and, considering the apparently conflicting interests at stake, much difference of opinion held on the matter; but we apprehend that most of the profession, who have taken an interest in it, will now admit that all that can be said upon the subject has been already many times said, and that we are now in a position, from the arguments *pro* and *con* before us, to come to some definite conclusion about it. We have already expressed our views; but, as we still continue to receive communications on this *ter quaterque vexata questio*, we shall once again repeat what, as it seems to us, is the fair and legitimate compromise which must be come to. The world lives by giving and taking.

Our conclusion, then, is this: that no private member of the profession can refuse to give the courtesy title of Dr. to any gentleman—Licentiate of a College of Physicians—who chooses to claim the title; that no member of the profession—no physician—who does not possess the university degree of Doctor, has the right of, or is justified in, appending to his name the letters M.D., unless he possess the right under some special powers of the charter of the College from which he has obtained his physician's license. We make this latter exception, because, as most of our readers are aware, the King and Queen's College of Physicians in Ireland claims that its charter contains special powers under which the College is enabled to grant the title of Doctor of Medicine. The College, we are told, is supported in its claim by strong legal authority, and is ready to try the question at law with any one who is willing to dispute the right.

But it will be seen at once, upon consideration, that this special claim of the King and Queen's College, founded on alleged special powers of its charter, gives no kind of right to the Licentiates of other Colleges—of the London and Edinburgh Colleges—to assume this title of M.D. On the contrary, it leads distinctly to the opposite conclusion; viz., that they have no right to the M.D. appendix, because the charters contain no such special clause as that above referred to. We need scarcely add, that neither of these Colleges makes any pretence to a claim of the kind; and we believe we are

quite right in saying that, in fact, any Licentiate of these Colleges, non-diplomatized, who does add M.D. to his name, is actually liable to the pains and penalties of prosecution under the Medical Act. Let it be understood that we are speaking of the Licentiates of the London and Edinburgh Colleges; for of the case of the King and Queen's College we have made an exception, and upon it we offer no definitive opinion, beyond what may be obtained from the *primâ facie* position assumed by that College, and from its readiness to try legal conclusions with any one who desires to dispute its claim.

The arguments in favour of giving the courtesy title of Dr. to any Licentiate who claims it are these. In the first place, it must be remembered that no doubt or difficulty occurred on the subject until the year of grace upset the even tenour of physicians' ways. It was only when physicians began to descend on the country from our Colleges like avalanches, that the doctors began to feel themselves disturbed; and truly every one must admit that it was rather a rude blow to the rare physicians and doctors of the previous days to find themselves all of a moment surrounded, and as it were swamped, by a suddenly created corps of new physicians. The ancient doctor naturally enough expressed a little surprise on finding, when he woke up in the morning, several of his medical neighbours, whom he had on the previous evening regarded as general practitioners, suddenly converted into doctors and physicians of Colleges, just like himself; and no one can be astonished that the aforesaid physician and doctor should be rather chagrined when he found how easily and pleasantly this conversion had been effected, and when he recollected the three days written and oral examinations which he himself had been subjected to before he had been able to obtain the like honourable title. No one can be surprised that there should, under such circumstances, have been utterings, mutterings, and murmurings.

Now, however, that time has mellowed down and made us better acquainted with the griefs of that year of grace, we are able to take a more calm and serene view of the case. And, in truth, as practical men, we are bound to judge it as it stands before us. Now it is idle and useless to pretend that Licentiates made during the year of grace, because they passed through no examination, are not as good, veritable, and true Licentiates, as any other Licentiates of the Colleges. The Colleges, in granting those licenses, acted with their eyes open, and are therefore bound to throw their equal mantle of protection over all their Licentiates. They cannot, with justice, distinguish an examined Licentiate from a year-of-grace Licentiate. One Licentiate, therefore, is in its eyes equal every way to another; and any injury which may have been temporarily inflicted upon the few Licentiates of other days by this large

year-of-grace creation of new ones must be regarded as one of those misfortunes which are necessarily incidental to all great movements—we mean, of the kind which unfairly hit the few whilst benefiting (as presupposed) the majority.

Such being the position of things, what we find is this: All Licentiates of Colleges of Physicians are of necessity physicians. Then, again, in the eyes of the community, all physicians are doctors; and there can be no doubt that a great many members of the profession took their physician's license under this general impression, conceiving that thereby they would win for themselves the title of Doctor. In fact, as is well known, a vast many doctors have sprung up in consequence of that year-of-grace licensing. But not only has the general sentiment of society in modern times made physicians and doctors synonymous terms, but the London College of Physicians has itself on various occasions permitted and sanctioned, and actually patronised, the assumption of Dr. by its non-diplomatised Licentiates. Now, without inquiring why the College did this, the fair inference to be drawn from the fact is, that the assumption was in its eyes in no way an improper or an immoral act. But, as the College had no power whatever to grant the title of Dr., it necessarily did so merely as a matter of courtesy. Why, then, it may be fairly asked, should not the profession use the same act of courtesy, if they think right to do so, and give the title of Dr. to those Licentiates who demand it?

True, the London College of Physicians has now altered its views, and refuses to address as Dr. those of its Licentiates who possess not a diploma; and so far it has reversed its former position; but it has done no more than this. It has not asserted that its Fellows, Members, and Licentiates shall not so give the title of Dr., if they please, to those of their Licentiates who ask for it. The College has, indeed, as far as we can judge, left the question an open one—every man being permitted to act according to his own lights and inclinations; and, if we are not much mistaken, there are very few if any Fellows or Members of the College who, privately, actually do refuse this courtesy Doctor title to those who ask it. So that, as private members of the profession, they do not stand by the conclusion which they sanction as members of a public corporation; and this clearly indicates that there is, at all events, some slight logical looseness in the screw of the corporation's resolution.

Thus, then, we find the following facts before us in favour of giving this courtesy title of Dr. to all Licentiates of Colleges of Physicians:—That Licentiates are physicians; that the public regard physicians and doctors as synonymous individuals; that the College of Physicians of London has itself sanctioned the affix of Dr. to its Licentiates' names; that

the Colleges of Physicians, when they were making Licentiates by hundreds during the year of grace, in their consciences (if corporations really possess such inconveniences) well knew that the Licentiates would take the title of Dr. with their license; that the Colleges do *not* direct or recommend their Members, etc., not to give the affix to non-diplomatised Licentiates; and that it is impossible, and would be most unfair, to attempt to draw any line of distinction between one set of Licentiates and another; and, therefore, that all are equally entitled to all the privileges which belong to "physicians". Lastly, we may add, that there is nothing illegal in the assumption of the prefix of Dr. And for these reasons we conclude that we cannot refuse to give the title of Doctor to any Licentiate of a College of Physicians who chooses to ask for it.

We must, however, in conclusion, state that for any non-diplomatised person\* to append to his name the letters M.D., appears to us to be doing that which is utterly without defence. He undoubtedly thereby subjects himself to the pains and penalties of legal prosecution; and, worse than this, we are satisfied that he will, in so doing, meet with the general reprobation of the profession.

### MEASLY PORK.

M. DELPECH has just read a paper at the French Academy of Medicine on the hygiene of measly pork.

The "leprosy" of pork, he concludes, consists in the presence of cysticerci in the tissues of the animal, and especially in its muscular tissue.

Taken into the human stomach with the meat raw or not well cooked, these animals are the most common, if not the sole source of the development of this entozoon.

The researches, however, of Weiss of St. Petersburg on the flesh of raw beef, and the curious facts collected by M. Judas from the reports of the military medical men, who have pointed out the endemicity of the animals in Algeria, show that further investigations are required to prove that the affection has no other origin.

The cysticerci exposed for some length of time to a temperature of 100° centigrade (212° Fahr.) are destroyed, and the flesh containing them thereupon loses its hurtful properties.

The cysticerci are rarely found in the fat. Measly pork, therefore, cooked in the neighbourhood of the abattoirs, under the surveillance of the police, may be safely employed as an article of food; and the fat may be also safely employed.

The cysticerci in the pig are derived from the ingestion of the ova of the *tænia solium*, or some other species of worms enclosing the ova, which they find

\* We of course exclude from this consideration the Licentiate of the King and Queen's College in Ireland.

in human excrements. This diseased condition of pork results originally from the filthy condition in which the pigs are kept.

It would be well to spread these facts widely and authoritatively amongst those who breed pigs. During life, the characters of this condition of the pig are obscure. The presence of sublingual vesicles, when it exists, is the only sure sign.

These different conditions have caused the authorities to prohibit the sale of diseased pork; but we may now consider that this prohibition should be removed. Moreover, the loss ought to fall on the person who fed the animal, and not on the butcher who buys it for sale. This would cause the breeder to be more careful in the keeping and feeding of his pigs.

### THE WEEK.

WE would call the especial attention of our readers to a letter signed "An Army Surgeon." The writer knows his subject well. The gross injustice to which he calls attention should be well understood in the profession. From the systematic way in which the Medical Department of the army has always been snubbed by the aristocrats at the Horse Guards, it appears evident that there is only one way by which the profession can wring justice from that quarter. The profession has certainly (if it would only exercise its powers) in its own hands the means of teaching the Horse Guards a lesson; and that is, by abstaining from entering into the army, until the equitable terms of agreement laid down by the late Lord Herbert are granted. At all events, the younger members of the profession would do well carefully to consider the actual worth of the position they will obtain by entering the army, before they don her Majesty's livery. Our correspondent certainly gives no flattering account of the position and prospects attached to it.

At a meeting of numerous friends (medical and general) of Mr. Adams, held on the 18th instant, at 5, Cavendish Square, it was resolved, that a public meeting should be called to express sympathy with Mr. Adams, as being the victim of an attempt to extort money; and to consider what steps should be taken to prevent unjust charges from being brought against medical and other members of society. An executive committee was appointed to carry out this resolution. The feeling in favour of Mr. Adams was universal and most strong. Much misconception, it was stated, had arisen in the public mind, and prejudice has been raised against him, in consequence of the report of the trial given in the *Times*. From this report, many persons have been led to think that

Baron Pollock summed up against Mr. Adams. Mr. Adams has, therefore, published the judge's summing up in full from the short-hand writer's notices; and a perusal of it will satisfy any one that the judge was, from the beginning to the end, in favour of Mr. Adams. Indeed, it appears certain that, had it not been that some twisted-minded person had been on the jury, the trial would have been stopped by the judge on the first day. The general feeling at the bar is clearly in favour of Mr. Adams. An eminent legal authority assures us that, in his opinion, the verdict of the jury in the case of Russell v. Adams was undoubtedly wrong—undoubtedly not justified by the evidence. It ought, he says, to have been simply a verdict for the defendant. The meeting referred to will take place early next week, and the public will then have an opportunity of manifesting their sympathy with Mr. Adams.

MR. COULSON has notified to his colleagues his resignation of his office of surgeon to St. Mary's Hospital. Mr. Spencer Smith will doubtless fill the vacancy caused by his retirement.

IN alluding, as we have often done, to the abuses practised in London hospitals by those who obtain improperly gratuitous medical advice, we have remarked that it is especially in the special hospitals that these abuses are most rampant. A remarkable instance of the fact came before the public at a late trial. A "gentleman of the name of Crump, a cashier," who, it appears, pays his governess forty guineas a year, obtains a letter, and sends his child to the Orthopædic Hospital, where it is treated gratuitously. Such a case needs no comment. Gratuitous advice given in this way is simply a robbery of the profession.

DR. STRUTHERS, Lecturer of Anatomy in the Edinburgh School of Medicine, has lately written a paper on the function of the round ligament of the hip-joint. Anatomists, as our readers know, have heretofore differed as to the uses of this ligament. Dr. Struthers now says:—"The function and the only function of the ligamentum teres is to check rotation outwards in the flexed position."

WE suppose that the supply always indicates a demand; and, therefore, must conclude that the following advertisements, taken from the *Daily Telegraph*, show the existence of a peculiar kind of traffic, which is going on spite of our famous and innocent Medical Act:—

"For Sale.—A Medical Diploma to be disposed of. For price, etc., send a directed envelope to J. A., care of Bookseller, 3, Spur Street, London, W.C."

"An Original Medical Manuscript to be disposed of. It is a first class production, and will bring both profit and prestige to the purchaser. Address, for interview, to Medicus, 3, Spur Street, London, W.C."

M. RENAULT informs the Academy of Sciences that during the last twenty-four years he has, at Alfort, made numerous experiments for the purpose of learning the period of incubation of hydrophobia in the dog. During that period, 131 dogs have, under conditions (which he describes), been either bitten by mad dogs under his own observation, or have been inoculated by him with the foam as immediately collected from the mad animals. Of this number, 63 having presented no signs of disease during the four subsequent months, were not further observed. Of the 68 others, the hydrophobia was developed at various periods, as shown in the following table:—

In	1 dog between the	5th and 10th day.

THE last number of the *American Medical Times* gives an engraving of the instruments of a notorious abortionist. They are fifteen in number, and of a most unsurgical-like appearance. They were found "at the establishment of the notorious abortionist, E. M. Browne."

"The complete collection contains forty different articles. The principal ones are here represented. They consist of spoon-handles, bent in different directions to suit the operator; several penholders with wire attached; one tack-hammer, with glass rod for a handle; one hair curling-tongs, altered to resemble a placenta-forceps; two porte-crayons, holding mustard-spoons; one large glass tube, closed at one end with wax and covered with cerate, containing cowhage (*mucuna pruriens*); together with catheters, bougies, etc."

His trade is for the moment arrested.

"Clementina Anderson, then between four and five months pregnant, entered this establishment to have an abortion produced. On the same day she was subjected to two operations by Dr. Browne; one in the morning, and the other in the afternoon."

In the end she dies, and so brings Mr. Browne into the hands of the law.

IRELAND is the country of anomalies. It is really difficult to understand why in Ireland alone Poor-law medical officers must be twenty-three years of age before they are fit for their duties. The *Dublin Medical Press* may well cry out for justice here:—

"The Poor-law Commissioners in Ireland make the attainment of the age of twenty-three years a necessary condition for obtaining an appointment to a dispensary or workhouse. At twenty-one years of age, a man is eligible, even in Ireland, to be placed in charge of a county infirmary; he may be appointed as surgeon or physician to any gaol, penitentiary, or lunatic asylum; no hospital in Dublin is closed against him on account of age; and her Majesty's service in the army or navy is open to him. Strangest of all, however, is the fact, that he is eligible for any Poor-law appointment in England and Wales. Can it be explained why in England a young gentleman shall at once enjoy the fruits of a successful course of study, and in Ireland he shall be literally punished for his diligence and promptness in the acquisition of professional knowledge. Surely this state of things is unjustifiable, and calls for a speedy alteration."

THE *Gazeta de Lisboa* relates a case of aneurism of the vertebral artery which was mistaken for aneurism of the carotid. It occurred in the Lisbon Hospital San José. The tumour occupied the left side of the neck, reaching from the ear down to within four or five *centimètres* of the clavicle. It was soft, elastic, and pulsated feebly, the pulsation being diminished by pressure on the carotid. There was no *bruit* audible over it. It was first thought to be an abscess, and afterwards a carotid aneurism. The ligature of this artery was, therefore, practised; but the pulsations of the tumour were not stopped thereby. In the evening of the day of operation, the patient became agitated, and three days later paralysis of the left side of the face occurred, with violent pain in the arm, which was also paralysed on the following day. The tumour was rapidly developed; dyspnoea, caused by pressure on the larynx, at last destroyed life about twenty days after the operation. The sac contained about 1000 *grammes* of blood, liquid and in clots, and communicated with the vertebral artery in its passage between the axis and the third vertebra.

The atmosphere of Strasbourg seems favourable to the operation of ovariectomy. Dr. Kœberlé of that city has, we read, practised it four times, and four times with success. His last case, however, was nearly fatal. On the twelfth day after the operation, in consequence of distension of the abdomen, the pedicle was ruptured, and hæmorrhage into the peritoneum occurred. Dr. Kœberlé thereupon opened the wound, sought for the pedicle, tied the ovarian artery (from which the blood escaped), and applied perchloride of iron to the pedicle. He then carefully removed all the blood from the peritoneal cavity, and closed it up again. No accident followed, and now, forty days after the operation, the woman is convalescent.

*L'Union Médicale* and the *Gazette Médicale de Lyon* still carry on a disputation respecting the propriety of advertising being permitted in medical journals. The Lyons journal says it cannot be necessary, for "our journal lives, and so do half a dozen more, who allow none of these lying documents (as he calls them) admission. The *Gazette Médicale de Paris*, the *Gazette Hebdomadaire*, the *Archives Générales*, the *Bulletin de Thérapeutique*, also all do well, and yet none of them admit advertisements."

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE Hunterian oration, now biennially given in the theatre of the above institution, was on Saturday last delivered by Professor Gulliver, F.R.C.S., before an unusually large audience. The orator, who was received most enthusiastically, commenced by admitting the difficulty at this day of finding absolute newness for comments on the valuable records of Hunter. In his time physiology and zoology were so oppressed by mere facts as to be in danger of sinking under their number, confusion, and weight, until he so surveyed and arranged them as to show their affinities and contrasts. Long before there had, indeed, been a sort of dead order, which it was reserved for his genius to mould by expositions of relation and difference, of unity of progression, or continuity of transition, or development, into a living method. No one can properly contemplate Hunter's unrivalled museum in connection with his writings without perceiving this great truth, nor without being impressed with the force of evidence by which the master spirit was led to the impressive and crowning conclusion that life is independent of or precedent to organisation. Moreover, a somewhat familiar acquaintance with his works has long since taught us to look up to him as the foreteller of many principles or central phenomena, only recently become well known by new or improved means of research, and claimed as late discoveries, in utter ignorance of his earlier observations. Among other instances, his description of the leading fact in the formation of the buffy coat of the blood was particularly worth notice, not only from its importance, but also because his priority in this respect was so little known or even suspected, and so long completely hidden, that it was left for Professor Gulliver to point out, in his course of lectures lately delivered, how the immortal Hunter had anticipated the main result of the excellent observations of Schroeder van der Kolk, Nasse, Henle, Wagner, and Wharton Jones. The orator then gave an elaborate history of the fibrine of the blood, and its vital endowments, of deep interest to the medical profession, together with notices of those physiologists who had confirmed Hunter's views on this important subject. Mr. Gulliver severely censured some of the authors of books, more particularly German works, placed in the hands of our pupils. "What," he asked, "is this plasma, protoplasm, blastema, or cytoblastema of these Germans, but the coagulable lymph of our own illustrious Hunter?" He added, amid considerable applause, that we had now adduced sufficient evidence to show that the Hunterian doctrine respecting the blood stood yet in all the majestic simplicity of truth, really unaffected by the more complex tenets of Schleiden, Schwann, and Valentin; that, in fact, even this single scene in the great drama, this little episode in the grand epic of Hunter's labours, would alone be sufficient to show the depth of his genius, and entitle him to the admiration and gratitude of all posterity. Since the last address had been delivered death had numbered among its victims such worthy disciples

of Hunter as Quekett, Norman, Stanley, and Brodie. The three latter died full of years and in the enjoyment of all that should accompany old age. Professor Quekett was early lost to science. He was one of the first, if not the very first, in this country of those eminent men who devoted their talents exclusively to the abstract branches of the profession, regardless of the meaner considerations of practice and profit. Though Mr. Quekett, like Pope, might truly have complained of "that long disease, his life," he retained to the last his wonted serenity and affability, kindness, and humility, unaffected by the plagiarism of his labours abroad, or even by the pitiful attempts of anonymous slander at home. The orator, in conclusion, paid eloquent eulogiums on the characters of Sir Benjamin Brodie and Messrs. Stanley and Norman.

## Association Intelligence.

### NOTICE REGARDING NEW MEMBERS.

By desire of the Committee of Council, the General Secretary requests that the Local Secretaries will be good enough to forward to him the names of all New Members who join the Association through the Branches; as otherwise the JOURNAL cannot be sent to them.

PHILIP H. WILLIAMS, M.D., *General Secretary*.

Worcester, November 10th, 1862.

### BRANCH MEETINGS TO BE HELD.

NAME OF BRANCH.	PLACE OF MEETING.	DATE.
BATH AND BRISTOL. [Ordinary.]	Athenæum, Corn Street, Bristol.	Thursday, Feb. 26, 7 P.M.
LANCASH. & CHESHIRE. [Ordinary.]	Royal Institution, Manchester.	Thursday, March 12th, 3 P.M.

### EAST KENT DISTRICT MEDICAL MEETINGS.

THE next meeting will be held at the Pavilion Hotel, Folkestone, on Thursday, March 5th, at 3 P.M.

THOMAS BOYCOTT, M.D., *Hon. Sec.*

Canterbury, February 10th, 1863.

### LANCASHIRE AND CHESHIRE BRANCH.

AN ordinary meeting of this Branch will be held at the Royal Institution, Manchester, on Thursday, March 12, at 3 P.M. Notice of papers, etc., to be sent to the Honorary Secretary.

A. T. H. WATERS, M.D., *Honorary Secretary*.

Liverpool, February 16th, 1863.

### SHROPSHIRE SCIENTIFIC BRANCH: ANNUAL MEETING.

A GENERAL meeting of this Branch was held at the George Hotel, Shrewsbury, on Friday, February 13th, under the presidency of ROBERT BLAICKIE, Esq., of Oswestry. A goodly number of members were present. Letters were received from many others, regretting that, in consequence of the great amount of sickness prevailing at the present time, they were unable to attend; and suggesting summer or autumn as a better period of the year for the meeting. This point was referred to the consideration of the Council of the Branch.

The President then gave an excellent and brief address.

*Papers.* The following papers were read.

1. On the Present Treatment of Disease. By W. Newman, M.D.
2. Case of Hemorrhagic Diathesis complicated with Renal Disease, producing Total Blindness: Dissection of the Eyes. By Professor Wharton Jones.
3. Case of Traumatic Tetanus from Compound Frac-

ture of Leg, in which Recovery took place on Division of the Internal Saphenous Nerve. By Samuel Wood, Esq.

4. A Handful of Scraps; being Short and Practical Notes on several Medical and Surgical Subjects and Formulæ for the Elegant Selection of the Gum Resins. By W. W. Morris, Esq., Clun.

5. Case of Lithotomy, in which Phagedænic Ulceration occurred, and Recovery after the Administration of Oxygen Gas. By William Eddowes, Esq.

*New Members.* The following members were then elected:—Charles J. Covernton, L.R.C.P. Edin.; William Eddowes, jun., Esq., M.R.C.S.

The members afterwards dined together, and a very agreeable evening was spent.

## Reports of Societies.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, FEBRUARY 10TH, 1863.

B.G. BABINGTON, M.D., F.R.S., President, in the Chair.

REPORT UPON SYPHILIS, IN ITS MANIFESTATIONS AS A CONSTITUTIONAL DISEASE.

BY JEFFREY A. MARSTON, M.D., ROYAL ARTILLERY.

[Communicated by HENRY LEE, Esq., F.R.C.S.]

AFTER referring to a previous paper,\* the writer gave a short *resumé* of prevailing doctrines. Upon the subject of one attack of true syphilis affording an immunity against a second, the writer made some remarks illustrative of its general truth, to which, however, there were a few rare exceptions. Under this category he gave a case, in which a soldier had been treated twice during eighteen months for indurated chancre.

The writer next briefly adverted to the comparatively modern reaction relative to the contagious character of secondary syphilis. He then passed to the subject of secondary sores upon the penis, commencing either by a recrudescence in the cicatrix of a former sore, or upon some part not previously diseased. These he described under three heads:—1. Such secondary lesions may commence as a circumscribed patch of purple or bluish redness, very slightly raised, from which the epithelium is shed, the surface becoming abraded, cracked, or covered with ill-formed and degenerating epithelial products. 2. This purplish-red spot, after becoming raised, takes on a chronic ulceration, similar to that of the scooped-out ulcers seen upon the tonsils. The first variety corresponds with, and often accompanies, a squamous or erythematous exanthem; the latter appears allied to the syphilitic tubercle, the ulceration of which plays so important a part in the evolution of syphilis in some subjects. 3. The third variety appears as a persistence of the ulceration, or an unhealed condition of the chancre, which becomes transformed into a mucous tubercle, as described by Ricord. Of these he gave illustrative cases.

Upon syphilitic infection, contracted from some other source than contact with a virus obtained from a primary lesion, the following were cited as in all probability instances:—

1. A wife and two children. The former had syphilitic nodes and an ulcerating tubercle upon the lower extremity. Of the latter (who slept with her) one was an infant, in whom the disease was probably hereditary, though not congenital in its outward manifestations; the other was a girl of five years, with anæmia, non-ulcerated sore-throat, engorged post-cervical glands, cutaneous syphilida of trunk, with psoriasis palmaris. All

had very restless nights. The husband lived separately, and was healthy.

2. The subject of disease was a military servant, a married man, who suffered from secondary and tertiary symptoms after intercourse with a woman known to be constitutionally syphilitic. Attempts to trace any primary lesion in this man failed.

3. The infection of a female by labial contact with diseased secretions from secondary lesions upon the lips of a male. The disease so produced in the female commenced as an irritable and indolent fissure upon the mucous membrane of the lower lip.

The writer next adverted to the evolution and succession of syphilitic symptoms as ordinarily witnessed among soldiers.

Under the cutaneous affections, he particularly remarked upon the mixed character of these; the majority of cases partaking of more than one affection at the same time, and upon the same or different parts of the body. Although great modifications in the future health and efficiency of the soldier were, doubtless, the result of syphilitic infection, yet cases of the more severe and intractable forms of constitutional disease were not very common.

With the view to prognosis, the writer said it was important to inquire, what relation, if any, has the severity of the primaries to those of the latter symptoms? From a consideration of his own observations, he inferred that the following were as approximate expressions to the truth as the facts warranted:—

1. The greater the induration, and the longer the period during which primaries remain unhealed, the more certain will it be that the constitutional infection will be severe.

2. The amount of ulceration, etc., of the primary sore stands in some relation to the worse and more intractable forms of secondary lesions—*e. g.*, the pustular, erythematous, and rupit eruptions,—the unhealthy ulcerations, nodes, and gummatous tumours.

The writer then passed to those cases in which there was an irregular evolution and succession of the stages and symptoms of syphilitic disease. Assuming that, when an indurated sore has been recognised, some specific treatment has been employed, and that soldiers are exposed to changes of climate, etc., we might infer, what is actually the case, that the constitutional symptoms would be irregular in their appearance and varied in their kind. As illustrative of his remarks, the author cited:—

1. A case of Hunterian chancre unhealed at the end of three months, when syphilitic rheumatism, and a node upon the left parietal bone appeared.

2. A case in which, three years after a sore upon the external integument of the penis, a soldier suffered from two attacks of jaundice, anæmia, nodes upon the tibiae, synovitis of left knee-joint, and rheumatism, without any history of secondary symptoms having been traced.

3. A case of repeated epileptic attacks, with violent pain in the head (upon which a node appeared), cured by specific treatment. The subject of the disease had suffered from repeated attacks of venereal disease, but not from any primary disease for two years and a half previously.

4. A case of chronic dyspepsia, slight icterus, pseudo-epilepsy, and paralysis of the third nerve. History of syphilitic attack two years before. Treated then by mercury. No history of secondary symptoms elicited by close questioning.

5. A case of osteocopic pains, paralysis of seventh nerve, followed by lichen and iritis, in a man undischarged from hospital for primary disease.

6. One of secondary syphilis, in which symptoms of intracranial inflammation appeared, followed by marked alteration of manner, loss of memory, dirty habits, etc.

7. Case in which there were—first, symptoms indica-

\* Syphilis, with reference to the more mixed and unusual forms of the primary symptoms. *Medico-Chirurgical Transactions*, vol. xiv.

tive of venous lymphatic absorption of pus, or some of the diseased products of secondary lesions; second, ocular disease, paralysis of third nerve, and other symptoms indicative of intracranial mischief.

The writer adduced also other cases, and made some remarks upon the character and nature of these nerve lesions.

As illustrative of the long interval which sometimes ensues between an attack of primary and secondary symptoms, he adduced the following:—

8. Lepra, psoriasis, and syphilitic cachexia, in a man who had not suffered from primary disease for nearly five years; he had been married for three, and his offspring were healthy.

9. Syphilitic cachexia, etc., in an infant, who died of the disease; the father not having had primary symptoms for four years, and having been subsequently the parent of one healthy child.

The author then spoke of the occasional latency of the syphilitic element, until some other disease or impairment of health appeared, which seemed to act as an exciting cause to its manifestation. He also remarked upon the modifications of diseases, or convalescence from them, that are sometimes, apparently, the result of a prior syphilitic infection. In support of the foregoing he gave some cases.

The paper concluded by stating the experience of the author to show that the effect of the Mediterranean climate upon the syphilitic diathesis was very inimical during the summer months.

#### ROYAL MANCHESTER INSTITUTION: MEDICAL SECTION.

FEB. 4, 1863.

E. LUND, Esq., in the Chair.

*West African Drugs.* Mr. ARTHUR RANSOME laid before the Society a collection of vegetable productions from West Africa, used by the natives for medical purposes. They had been forwarded to Mr. Thomas Clegg, a gentleman largely engaged in the promotion of cotton culture. Most of them were new to the members, and it was thought that there might be some of value; among others were a new vernifuge, several remedies for intestinal pains, and also several internal remedies for scabies.

*Cataract.* Dr. SAMUELSON showed a case of cataracta arida siliquata tremula in conjunction with atrophy of the iris. The patient was twenty-six years of age, otherwise healthy. The disease originated six years ago, without pain or inflammatory symptoms. The posterior capsule is a perfect, milky, concave disc, in front of which are yellowish white masses of irregular form and apparently cartilaginous hardness, and suspended, as it were, at the top only. As regards the iris, only a narrow light-coloured contour of varying width appears. The anterior layer is entirely absent, the urea alone remaining; the pupil, however, is round and dilatable. The globe is softer than its fellow, and slightly reduced in size. There is faint perception of light. The right eye is moderately short-sighted.

*Thermometer for Medical Purposes.* Mr. T. WINDSOR exhibited a cheap and accurate thermometer, of German manufacture, for medical use; and several members commented on the diagnostic value of the temperature in various acute diseases.

*Aneurism of the Aorta.* Dr. W. ROBERTS showed a preparation of a large aortic aneurism proceeding from the middle portion of the arch. It communicated with the aorta by a small round opening, and from the tumour appeared to spring the innominate and left carotid arteries. The case was interesting from the doubt as to whether this appearance was due to an aneurism arising between the origin of these two vessels, or to an abnormal origin of the latter from the former. Dr. Roberts inclined to the latter view of the case.

*Hydrocephalocele.* Dr. LORIMER exhibited a preparation of a case of congenital hydrocephalocele in a child ten months old. The general health had been good up till a few weeks before death, but the tumour rapidly increased while dentition was commencing. After an attack of measles, the skin over it sloughed, and gentle oozing of fluid took place; convulsions occurred at the close. The lateral ventricles were extremely dilated with serum. In the tumour was a pouch of membranes with a portion of cortical substance. The circumference of the tumour was ten inches.

*Apoplexy.* Mr. PEATSON exhibited a brain showing a large apoplectic hæmorrhage into the left side of the cerebellum. The symptoms were not observed during life.

*Chronic Arthritis.* Dr. LORIMER exhibited a preparation of the hip-joint showing an immense accumulation of osteophytes, the consequence of chronic arthritis following an injury of the joint.

*Pathology of the Retina.* Mr. HUNT read a paper on the Pathology of the Retina. He dwelt chiefly on the subject of muscæ volitantes, which he endeavoured to classify according to their seat of production and corresponding appearance. Certain forms be considered to have their origin in an actual change of the structure of the retina and of its circulation, and to exist independently of disease of the brain or optic nerve. These were characterised chiefly by their diffused cloudy appearance, of varying degrees of intensity. He promised to return more fully to the subject on a future occasion.

#### EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

FEBRUARY 4TH, 1863.

*The Calabar Bean.* An interesting paper was read by Dr. D. AREYLL ROBERTSON, on the Calabar bean as a new agent in ophthalmic medicine. Dr. Robertson related some experiments which he conducted, whereby he proved that the application of a spirituous extract of the bean to the conjunctiva caused myosis or contraction of the pupil, and induced a condition of temporary myopia or short-sightedness. These effects he ascribed to stimulation of the ciliary nerves, which he concluded was the action of the Calabar bean on the eye. The action of the Calabar bean was directly antagonistic to that of belladonna or atropine on the eye; and the one possessed the power of counteracting the effects of the other. The cases in which this new agent might be usefully employed, he said, were more especially those in which atropine had been employed with the view of aiding ophthalmoscopic examination, or of assisting in the exact determination of the state of the accommodation of the eye; cases of paralysis of the ciliary muscle, which frequently results from long continued debilitating diseases; and cases of ulceration at the margin of the cornea, where perforation and prolapsus of the iris may be feared.

*Phthisis and Insanity.* Dr. T. S. CLOUSTON read a paper containing statistics on the relations between phthisis and insanity. He pointed out many interesting facts; among them, that there is an increased percentage of phthisis (as ascertained by *post mortem* examination) among the insane; that the occurrence of phthisis in the general paralytic was extremely rare; and that in phthisical subjects the form of insanity was always marked by depression. When acute mania occurred in such cases, the patients neither made complete recoveries, nor subsided into a condition of progressive dementia, but, after the acute symptoms passed off, remained in an irritable condition, and in almost every case manifested in a marked degree monomania of suspicion. Where tubercle was found to exist in the peritoneum, the cases had all been of a melancholic nature.

## Correspondence.

### THE ARMY MEDICAL OFFICERS AND THE HORSE GUARDS.

SIR,—It is well known that the British Medical Association led in a great degree to the removal of the unjust position of inferiority in which the assistant-surgeons of the navy were formerly placed on board ship. The time seems now to have come when the attention of the members of the Association should be called to the treatment of medical officers in the army. The combatant authorities, in whom are vested nearly all influence and power, have undone so much, and evince such determination to undo still further, the work of two Secretaries for War, Lord Herbert and General Peel, as regards the medical profession in the army, and to stamp on the medical officers a status even lower in relation to themselves than existed before the issue of the Royal Medical Warrant, that now the interest of the whole medical profession seems concerned in the question. Moreover, there is now a want of medical officers. Young men are required for assistant-surgeons; but there can be no doubt that men of good attainments will not compete for commissions when they ascertain the opinions of their value, and what the chances of their future prospects are, from those who are already in the army. The feelings of disappointment and irritation which pervade the army surgeons are so deep, as no doubt now to be injuring their usefulness, and are evidently making some of them lose all pride in their vocation. An inquiry into the subject is therefore urgently required, and the more thoroughly it is sifted the better.

I will recall briefly one or two matters which relate to the present condition of the medical profession in the army. It is well known that medical officers had been for years prior to the Crimean war dissatisfied with their position relatively to other officers of the army; that the causes of their complaints were thoroughly investigated by the Royal Commissioners on the sanitary state of the Army, of which Lord Herbert was chairman in 1857; and that this dissatisfaction was then proved to be well founded and just. It was also shown that the position of the medical officers caused indirectly many evils to the army itself. In consequence, the Royal Commissioners advised the preparation of a new Warrant, ensuring to medical officers the rank, emoluments, and rates of retirement to which their services entitled them. This Warrant, framed by Lord Herbert, was issued with royal authority, by General Peel, in 1858.

Among the clauses of this Warrant was the following:—"The relative rank of the medical officers of our army shall be as follows: Staff, or regimental surgeon as major, according to the date of his commission, etc.," and again another, the seventeenth clause, which defined that, "such relative rank shall carry with it all precedence and advantages attaching to the rank with which it corresponds (except as regards the presidency of courts-martial, where our will and pleasure is, that the senior combatant officer be always president), and shall regulate the choice of quarters, rates of lodging money, servants, forage, fuel, and light, or allowances in their stead, detention, and prize-money. But, when a medical officer is serving with a regiment or detachment, the officer commanding, though he be junior in rank to such medical officer, is entitled to a preference in the choice of quarters."

In 1861, the surgeons were reduced from ranking as majors according to date of commission, and were ordered to take rank after all majors. This alteration caused so much dissatisfaction, that a year ago a committee was ordered to consider the matter. They reported that the

rank ought to be restored, and the medical profession was congratulated in the *Globe* ministerial paper on the prospect of its speedy restoration. The rank has not been restored; in consequence, it is asserted, of the influential objections of the combatant chiefs at the Horse Guards.

The seventeenth clause, quoted above, contains some of the most valuable of the privileges which were conferred by the Warrant; but, clear as its language and meaning are, those privileges have been systematically evaded or ignored. In this lies the main grievance of the medical officers. They are publicly told they have no rank, not even in the mess-room; that an ensign who may have just joined the army from school, has precedence over the oldest surgeon in the service, even in the ordinary ceremonies of the dinner table. No sooner was the Warrant published, than military orders were given in direct opposition to it, that no medical officer was to be allowed to sit as president of any committee, whatever its nature, where a combatant officer was present. If the experience of such a medical officer was required, he was only to be permitted to give information as a witness to the committee. If a medical officer claimed the horses, servants, or other allowances, such as the military officer of relative rank obtained, he was met with evasions, and the demand refused. If the Commander-in-chief obtains the allowances of a Field Marshal, he obtains nearly double the allowance for forage, for horses, that he had as a general, though no one could say that the increase was rendered necessary by additional work; and the same rule descends through the ranks of the combatants; but medical officers under corresponding circumstances are told that the rule does not apply to them. In India, the medical officers are told that none of the provisions of the Warrant have any force there at all, and to this hour its very existence is ignored in all three presidencies.

Another occurrence, quite new in its nature, has taken place several times during the past year, which has tended to undermine more deeply the confidence of medical officers in their position. Several surgeons have been dismissed from the service without any trial or court-martial, for asserted incompetency or misconduct, after years of service, without any statement being published in the *Gazette* containing the notice of dismissal, beyond the fact of their services being dispensed with. The current pay has never been regarded even by the authorities as full compensation for medical services, but only as part; the remainder being the rate of retirement according to length of service. Now all dependence on this provision is destroyed. The surgeons in the army regarded the Royal Warrant as a Charter of rights, and those who have entered the army since its publication were told by their teachers that it was a guarantee of the position they were to hold, and the recompense they were to receive for their services. They now find that, however clear the language of the Warrant itself may be, they have no guarantee for its just interpretation, and can there then be wonder at the prevailing discontent?

It is the custom for the combatant officers to urge as an excuse for their treatment of the medical officers, that the latter wish to assume military command. The medical officers deny this; they assert that they have no idea of coveting the province of the combatant officer. The seventeenth clause of the Warrant they seek the fulfilment of, and other clauses, settle all question of military command. They only desire to be on a fair footing with their brother officers, as gentlemen of at least an equally liberal profession should be, and to have the rights which the Warrant of 1858 conferred on them. They wish nothing more, and will never be content with anything less.

One other point: as before mentioned, assistant-surgeons are now wanted for the army. There are alto-

gether about seventeen hundred medical officers required for the Queen's forces, including India. The number of higher grades is very limited. It is calculated that, at the present rate of promotion, an assistant now entering the army will be from sixteen to eighteen years before he becomes a full surgeon. With such treatment existing, and such prospects before, can any but those who have no chance of occupation elsewhere, be looked for as competitors for army employment?

I am, etc., ARMY SURGEON.

February 1863.

# "O FORTUNATOS NIMIUM . . . AGRICOLAS."

SIR,—The "experiences of a country practitioner" constitute, so far as I am aware, the unwritten page of our medical literature; and doubtless would, if sketched by a master hand, form an interesting contribution to the annals of medicine.

Cut off to a large extent from much intercourse with his professional brethren, the country practitioner "lives, moves, and has his being," within a sphere of his own. There he is bound as by an iron chain, which so rarely admits of any lengthening out, as to afford him but few opportunities of coming into contact with the great world around him. He is necessarily thrown much on his own observation—largely on his self-reliance and promptitude of action—in the performance of the various duties which belong to his isolated position. How few of us live to make our names known beyond the limited circuit within which we range! We tread, in a professional sense, a kind of solitary pilgrimage through life, and then pass away,

"Alike to fortune and to fame unknown."

Still, let us hope our labours may not be altogether useless; and although we may say, with the apostle, that our days are chiefly spent "in journeyings often, in weariness and painfulness, in fastings often," yet, on the whole, I have no reason to think we endure either a discontented or an unhappy life. Such has been my lot for upwards of twenty years. I may, therefore, claim to speak, if not with the tongue of wisdom, at least with the voice of experience.

Like most of men, in early life I may have had my day-dreams, and indulged in the belief of a higher destiny and a more exalted station; but time has worn out all such impressions. I am now fully reconciled to my condition, and desire no change. I have lived long enough to learn that happiness consists, not in worldly distinctions, nor even in the acquirement of wealth, but depends rather on the preservation of health and a contented spirit. The possession of the former we may ascribe chiefly to the nature of our pursuits, which require us to spend a large portion of our time in the open air; the latter, I trust, we endeavour to cherish by a constant exercise of the mental faculties, and by allowing no time to be wasted in unavailing regrets. I know of no occupation which better tends to keep both mind and body in high working condition, than the daily avocations of an actively employed country practitioner. A brisk ride of thirty-five miles round the country is a most excellent cordial for a troubled spirit, aided by the additional diversion of attending to the various maladies of eighteen or twenty people during that interesting excursion.

Nature herself lends her bountiful aid towards enlivening our pursuits. We enjoy the delights of spring, the glories of summer, the beauties of autumn, and even the storms of winter. Each season, with its ever-changing landscapes, has its peculiar charms and delicious contrasts, and affords a perpetual feast of varied pleasure.

The geological features of the district in which we live may become a source of surpassing interest. I reside at the foot of an extensive range of chalk-hills, and have formed (so far as I know) a theory of my own to

account for their more prominent features. They are deeply excavated by winding valleys, evidently the beds of extinct streams; and the deposits or detritus left behind by the conflux of currents are as distinctly traceable as though the whole had been the work of a recent flood. The upheaval of the chalk is also shown by the varied inclination of the strata, which assume in some places a perpendicular form. The plain or level district below (known by the name of Cars) consists of an alluvial deposit, interspersed with beds of peat, marking the sites of a lacustrine vegetation; and beneath the surface are the remains of a submerged forest, as shown by the blackened trunks which have frequently to be dug up before the land can conveniently be traversed by the plough.

My sketch would be incomplete, if I did not say something concerning the character of the people. They may be divided into three classes; the first comprising the local gentry and clergy; secondly, the farmers, with whom I would also include those who live by trade or mechanical pursuits; and lastly, the agricultural labourers. Amongst the latter, it is commonly the fate of the country practitioner to be largely patronised. I am sorry to add, he receives little else in return for his services. Their apparent reliance upon him, however, in the hour of need, and the anxious manner in which they seek his help, usually overcome all his scruples; and in most cases he obeys their calls promptly, and bestows upon them his best care. On this account, I believe, the poor rarely suffer, even in our remotest districts, from want of proper medical assistance.

The farmers, as a rule, are our best friends. As a class, they are noble fellows; and though they may want the exterior polish which bespeaks a refined education, and display at times a roughness and sternness of manner, they are generally true and sound at heart. Their hospitality is unbounded; you may dine with them every day, and find a welcome. I merely mention this as an illustration of their character.

The gentry, unfortunately, do not figure largely in the ledger of the country practitioner. Each family appears to have its "town" physician, who, as one might suppose, provides a batch of prescriptions suitable for the various disorders, both present and to come. These, of course, find their way to the chemist's shop. The "village doctor" is merely summoned under the same conditions as the country tailor; viz., in cases of great emergency. I have heard it intimated that this feeling has been sometimes fostered by the metropolitan practitioner; but I, for one, am reluctant to believe it.

Our practice, I need scarcely say, partakes more of a medical than of a surgical character. Unlike our professional brethren living in the mining or manufacturing districts, we rarely meet with severe accidents acquiring the aid of operative surgery. When they do occur, I am not aware of any lack of the usual disposition or ability—as a great warrior once said of his soldiers—"to go anywhere or do anything". I have known a country practitioner to amputate a leg successfully—I may say single-handed, save and except such *impromptu* help as he could obtain by selecting the steadiest nerves around him to hold the candles and hand him the instruments.

Fractures and dislocations, laceration of limbs, etc., not unfrequently come under the care of the country practitioner; but the larger operations of surgery he is seldom called upon to perform. Nevertheless, he considers it his duty to keep "his case of instruments" in proper order, in the event of any necessity arising, to require their employment.

Midwifery constitutes rather a large element of our practice; and, if I may so speak, is the bane of our peace. Like some of our heavenly bodies, these cases occur at very irregular intervals—at inopportune and unexpected times—and altogether disarrange our calcula-

tions and movements. They interrupt our daily rounds, rouse us from our sleep, snatch us from our meals or away from the society of our families or friends—everything, in fact, must yield to their imperative calls. Like all other evils, however, they happily come to an end; and we return home, thankful to be released from the imprisonment we have undergone whilst Nature has been engaged in performing her slow yet admirable office.

Now and then we are roused to activity by the occurrence of one or other of those painful complications connected with this department of our profession, with most of which we are too familiar; and they not unfrequently subject us to severe trials. The operation for turning; the employment of the forceps; the performance of craniotomy; or (what we dread, perhaps, the most of all) the supervision of hæmorrhage,—have each to be encountered, without any further assistance than can be secured from the ancient matrons of a country village.

Our obstetrical practice on the whole, I believe, is very successful, as many a country practitioner can testify by referring to a long career of practice without having had the misfortune to lose a single case.

In my younger days, I can remember an old-fashioned country doctor, who enjoyed a great reputation for his success over a wide district. He was a thin, wiry man, somewhat bent with age and long service, but yet active, and a cheerful, hopeful, good-hearted soul. His neck was enveloped in a large "comfortable"; his lower limbs encased in mahogany top-boots, "for his shrunk shanks a world too wide," and apparently constructed for the better convenience of leaping into or leaping out of them at a moment's notice. He also rode a thin gaunt horse, which had a character for endurance only next to that of its master: and to see him perched on an ante-diluvian saddle, equipped for his journey, was a view of earthly glory not soon forgotten. Poor old man! his labours have long ceased; yet his name is remembered with affection, and spoken of with reverence amongst the hills and valleys where he was so long regarded as the "ministering spirit".

The prevailing complaints of our country districts are, as a rule, stern realities, and rarely belong to the imaginary type. Inflammatory diseases assume an acute form; and fevers rage high amongst the well-fed and well-conditioned residents of our agricultural villages.

I still adhere so far to the "old school" as never to go abroad without a lancet in my pocket; and, in spite of the doctrines now taught by modern physic, I retain some faith in that useful, though formidable little instrument. I have known cases of pleuropneumonia, peritoneal and enteric inflammations, and congestive affections of the brain, apparently cut short by a moderate bleeding. The relief, at least, has been simultaneous with the employment of the remedy; and, therefore, so far as human judgment could decide, might fairly be considered to stand in the relation of effect to cause.

Some distinction is certainly allowable betwixt the judicious use of an established remedy, and its entire abandonment. It is a wise maxim, "to stand fast in the old ways—cleave to that which is good," especially where, so far as venesection is concerned, we have it now displaced from its once accredited position as a valuable agent in the treatment of disease, without leaving us anything behind as a reliable substitute in its place. Most practitioners of the present day depend more upon a careful direction of the efforts of nature towards the removal of disease, than upon their own heroic exertions; and he best fulfils his trust, who knows when and how to assist, and when to withhold.

In all cases of fever, whether typhus, typhoid or exanthematous, bleeding, I believe, is never employed even in country practice. We adopt the sustaining system early; favour the action of the skin, as being the safest

source whence "poison" may be eliminated; and administer wine and stimulants in moderate quantities. The bowel-complications of typhoid fever are generally most to be feared; and the worst cases of this kind which I have witnessed have occurred where the patient has injudiciously taken a "lot of physic" at the onset of his illness. Where hæmorrhage has come on, the acetate of lead with opium has been in my hands by far the most serviceable remedy. I entirely accord with the views of Dr. W. Budd on the propagation of fever through the medium of the alvine excretions. I have often been able to trace its extension to that source, and could furnish one or two striking illustrations, if space would permit.

I have also noticed the prevalence of epidemics, whether of scarlatina, measles, small-pox, or fevers, that each, so to speak, has had a reign of its own—that these different disorders rarely intercalate with each other. Are we to infer each depends upon some specific virus, spread abroad under a condition of atmosphere favourable for its propagation? or that it arises from some change in the ordinary constituents which directly produces such outbreaks? Contagion does not always satisfactorily account for the occurrence of cases, often far apart from each other, or where the least communication with others suffering from a similar malady has never taken place.

I must now conclude. It has been my humble endeavour to describe the thoughts and occupations of a country practitioner—one of a class who may be safely regarded as "outsiders" in the race for professional honours. We may run, but never hope to gain the prize. We yet feel ourselves as belonging to a great commonwealth, which has its representatives even in remote corners and obscure localities, who labour, I trust, diligently and usefully, and under a full sense of the responsibilities connected with a noble calling. We hope to gain our reward, if not in riches and honours, at least in the respect and approbation of those amongst whom it is our lot to toil, whilst endeavouring honestly and faithfully to dispense those blessings which no other profession can so richly bestow as our own.

I am, etc., "VOX RURE."

January 20th, 1863.

## DR. SALTER'S LECTURE ON THE STETHOSCOPE.

LETTER FROM H. DOBELL, M.D.

SIR,—In Dr. Salter's very excellent lecture on the Stethoscope, there are two points relating to the shape of the instrument, in which I think he is slightly in error; and I shall be obliged by your allowing me, through your pages, to submit what appear to me to be the corrections.

1. Dr. Salter says:—"The ear-piece should be large, for the very same reason that the chest-end should be small—to secure apposition and occlusion; for the larger it is, the less critically exact and central need the apposition of the ear to it be in order to prevent chinks and a want of coincidence between them."

I submit to Dr. Salter, that there is a natural limit put to the proper diameter of the ear-piece by the zygomatic prominence. If the half diameter of the ear-piece—that is, from its margin to its central bore—be greater than the distance from the external meatus to the zygomatic prominence, one of two things must happen; either the central bore must be placed to the rear of the meatus, or the ear-piece must be tilted up by resting on the zygomatic prominence, and thus "chinks" will be left, and proper "apposition and occlusion" will be impossible. The diameter given by Dr. Salter—viz., three inches—is too large for the majority of ears. A circumference of seven inches for the ear-

piece, I have found to be the largest which the majority of persons can use, without either resting it upon the zygomatic prominence, or removing the central bore to the rear of the meatus.

2. I quite agree with Dr. Salter, that "the chest-end should be small"; that is a very important point when the stethoscope is required for defining rather than for exploring—and it is for defining that this instrument is especially valuable; but I think it is a mistake to have "the edge narrow," as described and figured in Dr. Salter's lecture. He thus loses two advantages: first, a wide conducting surface of wood; and secondly, a greater safety from the admission of air beneath the stethoscope by slight inequalities in the surface of the chest, or by accidental tilting of the instrument. In my opinion, the chest-end should have as broad a surface of wood as its size will admit of, and this surface should be rounded off towards the circumference and towards the central bore, so that the line of greatest convexity shall form a circle about midway between the circumference and the central bore. This secures the most accurate apposition with the least trouble in adjusting, and, having no sharp edges, presents a very comfortable surface to the patient's skin.

Allow me to add to these remarks that, by marking out the circumference of the flat surface of the ear-piece into inches and parts of an inch, a gauge is provided, which, by rolling the ear-piece like a wheel over a part, can be used for measuring any extent of surface either large or small. Stethoscopes comprising the advantages recommended by Dr. Salter, with the addition of such as I have here pointed out, are constructed with great care by Messrs. Maw of Aldersgate Street, and sold under the name of the "gauge stethoscope."

I am, etc., HORACE DOBELL.

29, Duncan Terrace, Feb. 11, 1863.

## THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

LETTER FROM B. W. FOSTER, M.D.

SIR.—Your correspondent Δ. in his letter which appeared in the BRITISH MEDICAL JOURNAL of January 31st, on the power of the King and Queen's College of Physicians to grant the title of M.D., seems to entirely misconstrue the judgment of the Court of Queen's Bench. On reading the trial, it will at once be seen that the case did not at all turn upon the power of the King and Queen's College of Physicians to confer the M.D. The application of my friend Dr. Barker was refused, *only on the ground that the King and Queen's College of Physicians was not enumerated in the schedule of the Medical Act as granting the degree of Doctor of Medicine*. The last sentence in the abstract of the judgment, sent by your correspondent, proves this; viz.: "The applicant, Mr. James Barker, jun., had a diploma from the College of Physicians (K. & Q.C.P.I.); but that was not any of the qualifications mentioned in the schedule entitling him to be registered as a Doctor of Medicine." Dr. Barker lost his case, simply from the fact that the Medical Act had not recognised his College as conferring the M.D.; and therefore the Registrar, acting under the provisions of that Act, could not be compelled to register it. The court carefully refrained from expressing any opinion as to the powers contained in the charter of the College; and stated, moreover, that even if the power of the College to grant the M.D. were admitted, it would not entitle Dr. Barker to the *mandamus* he applied for, as it was not one of the qualifications enumerated in the schedule of the Act.

Your correspondent's remarks as to the comparative value of the opinion of the Attorney-General, and the decision of the Court of Queen's Bench, are, on a clear conception of the case, simply absurd. The opinion of

the Attorney-General was given as to the power contained in the charter of the College; whereas the decision of the Court of Queen's Bench, without denying the powers of the charter, only held that the degree could not be registered according to the provisions of the schedule of the Medical Act. The production of the charter could have had no effect in altering the judgment of the Court, as no other decision could be arrived at, with the schedule of the Act retaining its present form.

I am, etc., B. WALTER FOSTER.

Birmingham, February 7th, 1863.

SIR.—I cannot for a moment suppose that your correspondent Δ, in his last letter to the JOURNAL, intentionally perverted the truth in the matter of the decision therein alluded to. I would, therefore, in reply thereto, merely remark that the Court of Queen's Bench in Ireland gave no decision whatever on the right of the Licentiate of the King and Queen's College to the title of M.D. The whole legal question there involved was simply this. The King and Queen's College applied for a *mandamus* to compel the Branch Council to insert the title of M.D. in the *Register*, as an additional qualification; and the court ruled that it was not within their power to do so, as such title was not specified in Schedule A of the Medical Act. The decision went no further. It left the right untouched.

If, as certain internal evidence would seem to indicate, Δ is a resident of the Irish metropolis, he can probably inform your readers why the authorities of Trinity College, who some months ago intimated their intention to try the right of the King and Queen's College to confer the doctorate, have refrained from doing so, although duly informed by the latter College that they were fully prepared to accept the challenge and have the question adjudicated upon.

The gauntlet has again been thrown down by the College; and, should Δ or his College feel disposed to take it up, and try the point in a court of law, either in England or Ireland, the writer will be happy to afford him every facility; and, with that view, encloses his name to the editor for Δ's information, and in the meantime subscribes himself,

L.K. & Q.C. and M.D.I.

February 11th, 1863.

## THE TITLE OF DOCTOR.

LETTER FROM HUGH MORRIS, L.R.C.P.Ed.

SIR.—I am sorry to take exception to anything that appears in the pages of our JOURNAL; but I must protest against the tone of the letter signed "F.R.C.S." in the number for the 7th instant. "Unscrupulous," "falsehood," "humbug," "imposing," "cheating the public," are words a gentleman does not generally use lightly.

Even if he have met with uncourteous or unfair behaviour on the part of his opponents, that can be no excuse for his denouncing in such terms the whole body of Licentiate of the Royal College of Physicians of Edinburgh, or for his further insinuating that no examination was submitted to by any of them.

While writing his *nom de plume*, he may not have recollected that some few years since at least as many Fellows were created by the London College of Surgeons without any examination, as Licentiate by the Edinburgh College of Physicians in the year 1859; and for myself, I cannot think it a disgrace to have received my diploma from the latter, after being examined by such men as Drs. Craigie, W. T. Gairdner, and Keiller.

There are many of us who, without the desire to aggrandise ourselves at the expense of our professional brethren, contend that we have an undoubted prescriptive right to use the courtesy title of Dr., and the public seems likely to fall in with this opinion. I believe also that some (I can truly speak this of myself) only as-

serted that right in consequence of the gross and ungentlemanlike abuse that was heaped upon us Edinburgh Licentiate at the commencement of this controversy.

In conclusion, I cannot speak too strongly against the common practice of writing anonymously on subjects involving great difference of opinion. I think it leads to more ill-feeling by far than would arise from a contrary course, and that a man would often blush to read his own name at the foot of a letter using ugly words towards his neighbour; while he would regard the same composition with complacency if finished off with F.R.C.S., or any other pseudonym behind which, as behind an ambush, he may think it prudent to conceal himself.

I am, etc.,

HUGH NORRIS.

South Petherton, February 9th, 1863.

SIR,—Surely "F.R.C.S." allowed his feelings to outrun his judgment in inditing so remarkable a diatribe. His views and opinions on the question of medical titles appear to be as superficial and erroneous, as his objects are palpable in selecting the Edinburgh Licentiate for vituperation. Is it not, Mr. Editor, manifest that he designedly shelters himself under an anonymous signature for the purpose of charging grave and serious offences against a brother-practitioner, well knowing there can be no opportunity of rebutting them?

I will not occupy your valuable space by entering upon a discussion already worn threadbare, and which, if prolonged indefinitely, can neither abrogate nor affect the right of physicians to the title of Dr.

One erroneous statement of "F.R.C.S." I cannot permit to pass uncontradicted. The Manchester Medico-Ethical Association has never resolved that a Licentiate of a College of Physicians was not entitled to be called Dr.; nor has it once interfered in the question of medical titles.

I am, etc.,

L.R.C.P.Ed. and F.R.C.S.E.

February 9th, 1863.

SIR,—I was much amused with the letter of F.R.C.S. on the title of "Doctor", in last week's JOURNAL. He, a Member of the College of Surgeons, pays £10; and without examination, or leaving home, takes the title of "Fellow", and no doubt considers himself much superior to his neighbour who is only "Member". I, a Member of the College of Surgeons, pay £10 to the College of Physicians of Edinburgh; and, after a most practical and strict examination (which I think F.R.C.S. will find in the JOURNAL for Oct. 1st, 1859), am "snubbed" because I take the title of "Physician" or "Doctor", which I believe I have a right to assume.

I also beg to state, for the information of F.R.C.S. (who says that the College refuses to give us the title of "Dr."), that on receipt of a circular from the Edinburgh College a short time since, it was directed "Dr."

I am, etc., L.R.C.P.Ed. BY EXAMINATION.

P.S. Of course I do not allude to the F.R.C.S. by examination.

February 13th, 1863.

SIR,—There is one circumstance connected with the use of the title of Dr. which does not seem to be generally recognised, but which in some measure strengthens the editorial remarks you have appended to the letter of a correspondent in your impression of Feb. 7th.

In the well known address of Launce to his dog, in the *Two Gentlemen of Verona*, that practical philosopher, among other hints at the cur's imperfections, says:—"I would have, as one should say, one that takes upon him to be a dog indeed; to be, as it were, a dog at all things." Now, this is precisely the position of many graduates who object to their licentiate brethren using the title of Dr.

The words "Doctor of Medicine" have, from time immemorial, implied something more than the fact that the person using the title has graduated at an university. Among gentlemen, and in the higher walks of the profession, a "doctor" has always meant a "physician," one who "took upon him to be a physician indeed; to be, as it were, a physician at all things."

Will the graduate who claims this title and pursues his art as a "general practitioner", consent to forego that general practice and confine himself to the office of a physician. I do not think he will be ready to make any such sacrifice; but until he does so, he must submit to the other alternative, and acknowledge that what has been claimed by the licentiate in courtesy has been forfeited by the graduate in practice.

I am, etc.,

CHIRURGUS.

February 9th, 1863.

SIR,—Permit me to thank you for your editorial remarks appended to the epistle of "F.R.C.S." in the number of the JOURNAL for Feb. 7th. I, sir, am one of the "gentlemen, non-diplomatized," i.e., non-graduated, "to whom the London College of Physicians many years ago actually gave distinct permission to take the title of Dr." So far as the "gift of the Dr." is concerned, I would beg leave to add, it was, or is, not "tacitly," but openly and avowedly, made to me, and conveyed, *bona fide*, by the word *titulis* in my diploma. On examination, being found a most proper man (*ornatissimum virum*), I was permitted both to practise and to teach medical science; and I was given, moreover, to enjoy the highest "honours," "titles," and "privileges," common to physicians, here and everywhere.

These words, written in Latin, I see before me in my diploma of the College of Physicians of London. What I complain of, more particularly in company with many members of years standing, is that the governing body of the College did not, previously to the creation of the famous by-law,\* which undoctored so many, offer to us some kind of explanation, if not apology, for the course taken, or rather about to be taken. An act of courtesy of this kind would have gone far to put the matter on a more pleasant footing than it now assumes. As it is, I cannot help feeling that could I recall the last twenty-one years of my life, I would then either have been content as a surgeon and apothecary, or have gone northwards for the M.D. degree. It is no joke to a man engaged day by day in the work of our calling to have to relearn the odds and ends of anatomy, chemistry, materia medica, pharmacy, etc., and to polish up yet again old Celsus, Heberden, and others of this class; and, what is more, to pay a sum of money in exchange for even a courtesy title; but this much is now withheld by "my college"† from

Yours, etc.,

M.R.C.P.LOND., etc.

February 9th, 1863.

SIR,—In the JOURNAL of the 7th instant, you have appended some remarks on the title of Dr. in a spirit of great liberality, which I hope will settle that *questio vexata*, the right or claim of using the title. I possess a German degree and am also a Fellow of the College of Surgeons and Licentiate of Apothecaries' Hall, and some time ago I thought it well to pass the London College of Physicians, fully believing that it was the highest medical society in Britain, and that its diploma conferred the absolute right of a title of M.D. In the old charter, when the President confers upon the candidate the dignity of being a Licentiate, he says: "Cum honoribus, *titulis*, et *privilegiis*." Besides, if the College gives the right of practising and *docendi*, how can a man do that unless he is *doctus*, or substantively doctor.

\* This ought never to have had a retrospective operation; herein the College erred.

† See letter by F.R.C.S.

The year of (*dis*)grace did the College an irreparable injury in public estimation; the doctors now are as thick as mackerel. The distinctive honour of being a member of the Royal College of Physicians of London is gone; it is levelled down to the dust. The new Licentiates are calling themselves physicians! Quantum mutati ab antiquis medicis! I confess I am sorely grieved that the venerable old College, chartered by Henry VIII, did not preserve its ancient dignity as a College of Physicians exclusively. Now you have surgeons and apothecaries licensed by the College of Physicians. It is a decided come down; the status is degraded.

I am, etc., R. W.

February 9th, 1863.

## Medical News.

**ROYAL COLLEGE OF SURGEONS.** The following members of the College, having undergone the necessary examinations, were admitted Licentiates in Midwery at a meeting of the Board, on February 11th:—

Anderson, Edward Charles, Birmingham: diploma of membership dated November 18, 1862  
 Baker, Thomas, Birmingham: November 18, 1862  
 Bloxam, Matthew, Duke St., Grosvenor Square: Nov. 20, 1862  
 Bodwell, G. Granville, Rathmullan, co. Donegal: July 31, 1861  
 Cook, John, Fitzroy Place, Kentish Town: November 5, 1859  
 Elliot, Richard Luscombe, Kingsbridge, Devon: May 7, 1862  
 Emmett, William Henry, Bolton-le-Moors: January 30, 1862  
 Fisher, Stephen Winter, Bristol: August 1, 1861  
 Hollis, William Pottinger, Burton Crescent: March 8, 1861  
 Holt, John, Bolton, Lancashire: May 8, 1862  
 Lloyd, Samuel, Smethwick, near Birmingham: Nov. 15, 1860  
 McDiarmid, Albert, Rochester: June 10, 1862  
 Morgan, William Taylor, Dreadnought Hospital Ship, Deptford: January 14, 1859  
 Richards, Samuel Smith Crosland, Bedford Square: July 29, 1862  
 Sheldon, Thomas, Stratford-on-Avon: December 5, 1859  
 Wine, Henry Charles, Bristol: June 4, 1861

### APPOINTMENTS.

BRADLEY, Samuel M., Esq., appointed Physician's Assistant at the Manchester Royal Infirmary.  
 BRITTAIN, Thomas L., M.D., elected Assistant House-surgeon to the Chester Infirmary.  
 FORBES, David, M.D., appointed Surgeon to the Glasgow Lock Hospital.  
 GERVIS, Henry, M.D., appointed physician to the Surrey Dispensary.  
 MACDONALD, Keith N., Esq., appointed Resident Medical Officer to the Bath Eastern Dispensary.  
 \*MASON, Frederick, L.R.C.P.Ed., appointed Surgeon to the Bath Eye Infirmary.  
 MATTHEWS, Charles S., Esq., appointed Surgeon to the Farringdon General Dispensary.  
 NUNN, Thomas W., Esq., appointed surgeon to the Middlesex Hospital.  
 SCHOLLICK, Thomas J., Esq., appointed Resident Medical Officer to the Guildford and West Surrey Dispensary.  
 WATSON, William, Esq., appointed Honorary Surgeon to the Lancaster General Dispensary.

**THE PRINCE OF WALES'S HOUSEHOLD.** His Royal Highness the Prince of Wales has made the following medical appointments to his household.

JENNER, William, M.D.	} To be Physicians in
*STEVING, Edward H. L., M.D.	
*PAGE, James, Esq., F.R.S.	} To be Surgeons in
*POLLOCK, George, Esq.	
MINTER, John, M.D., R.N., to be Surgeon Extraordinary.	
*CHAMBERS, Thomas K., M.D.	} To be Honorary Physicians.
*ACLAND, Henry W., M.D., F.R.S.	
ARMSTRONG, Alexander, M.D., R.N.	

### POOR-LAW MEDICAL SERVICE.

CONSTABLE, John, M.D., to be Parochial Medical Officer for Lechlairs, Fife.  
 JOHNSTON, Robert, M.D., to be Medical Officer for the Bellaghy District of the Magherafelt Union, co. Londonderry.  
 MACKENZIE, Duncan, Esq., to be Parochial Officer for Kilsyth, Stirlingshire.  
 REA, Hugh P., M.D., to be Medical Officer to the Southfield District of the Belfast Union.  
 WILDE, John, L.R.C.P.Ed., to be Medical Officer to the Winchester District of the Winchester Union.

### ROYAL NAVY.

DRIGAN, Patrick, Esq., Surgeon, to the *Cestor*.

OWIN, Thomas W., Esq., Assistant-Surgeon (additional) to the *Cumberland*.

### DEATHS.

CAVELL. On February 14th, at Oakley Square, Camden Town, aged 80, Sarah, widow of the late Charles Cavell, Esq., surgeon, of Bardwell, Suffolk.  
 CHALDECOTT, Frederick W., M.D., at Sydney, aged 27, on December 22, 1862.  
 MURRAY. On January 2, at Port of Spain, Trinidad, aged 26, Richard Henry Murray, barrister-at-law, eldest son of Thomas Murray, M.D., of Trinidad.  
 RPOUT. On February 15, at Egham, aged 19, Louisa, daughter of G. V. Ridout, Esq., surgeon.  
 THOMAS, John, Esq., surgeon, at Ladbroke Place West, on Feb. 15.  
 YONGE. On February 8, at Plymouth, Devon, Elizabeth B. A., wife of John F. D. Yonge, M.D.

**BIRTHS AND DEATHS REGISTRATION (IRELAND.)** This bill has been read a second time.

**UNIVERSITY OF OXFORD.** Mr. F. C. J. Griffin of Weymouth, B.A., Lincoln College, has been elected to the Radcliffe Travelling Fellowship.

**METROPOLITAN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.** The next meeting will be held this (Saturday) evening, at half-past seven o'clock, at 8, Richmond Terrace, Whitehall. A communication will be read from the secretary of the Epidemiological Society, respecting the proper registration of sickness among paupers. Mr. Chadwick will make a proposal in reference to an application to Parliament on the sanitary requirements of public schools. At eight o'clock, Dr. Murchison will read a paper on Continued Fever. A communication on the Fever of Canterbury will be read by Dr. Boycott.

**BEQUESTS.** By the will of Miss Rosa Frances Lewis of Cadogan Place, the only daughter of the late Mr. W. T. Lewis, the celebrated comedian, the following medical charities, along with several other institutions, receive bequests; namely, to St. George's Hospital, £200; the Hospital for Consumption, Brompton, £200; the Asylum for Idiots, £100; the Lying-in Charity, Liverpool, £200; the Infirmary, Brownlow Hill, £200; and the Dispensary, Vauxhall Road, Liverpool, £200. The sums left by Miss Lewis in charitable objects amount to £14,000; and by her death, a sum of £10,000 and the portrait of her father by Sir Martin Shee revert to the National Gallery.

**RUSSELL v. ADAMS.** On Wednesday afternoon an influential preliminary meeting was held at No. 5, Cavendish Square, Dr. Brady, M.P., in the chair, at which a resolution was unanimously passed, calling a public meeting, and inviting members of the learned professions and the public, to take into consideration the best means to suppress the increasing practice of attempting to extort money by false charges. A resolution was also passed electing a general and executive committee. The following gentlemen were present:—W. Coulson, Esq.; Borlase Childs, Esq.; I. B. Brown, Esq.; J. F. Clarke, Esq.; Haynes Walton, Esq.; Dr. Markham; Spencer Wells, Esq.; W. Harvey, Esq.; G. Lawson, Esq.; Dr. Leared; Dr. Wynn Williams; Dr. Dick; H. Thompson, Esq.; W. L. Leaf, Esq.; H. H. Cannan, Esq.; John Churchill, Esq.; Ernest Hart, Esq.; J. Tomes, Esq.; S. S. Scriven, Esq.; Dr. Brown-Séquard; John Chapman, Esq.; W. F. Low, Esq.; A. Fisher, Esq.; Erasmus Wilson, Esq.; Br. Bloxam; John Gay, Esq.; John Erichsen, Esq.; Dr. Cape; Dr. Ross, etc. The following executive committee was elected:—The chairman, Dr. Brady, M.P.; John B. Walker, Esq., 17, Clifton Gardens, W., Hon. Secretary; W. L. Leaf, Esq.; B. W. Richardson, M.D.; J. Dangerfield, Esq.; Mr. Sheriff Jones; T. Spencer Wells, Esq.; H. H. Cannan, Esq. The proceedings of the meeting were enthusiastically received, and terminated with a vote of thanks to the chairman.

## OPERATION DAYS AT THE HOSPITALS.

MONDAY.....Royal Free, 2 P.M.—Metropolitan Free, 2 P.M.—St. Mark's for Fistula and other Diseases of the Rectum, 1.15 P.M.—Samaritan, 2.30 P.M.—Lock, Clinical Demonstration and Operations, 1 P.M.

TUESDAY. .... Guy's, 1½ P.M.—Westminster, 2 P.M.

WEDNESDAY...St. Mary's, 1 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.

THURSDAY....St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—London, 1.30 P.M.—Great Northern, 2 P.M.—London Surgical Home, 2 P.M.—Royal Orthopædic, 2 P.M.

FRIDAY.....Westminster Ophthalmic, 1.30 P.M.

SATURDAY....St. Thomas's, 1 P.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY. Medical Society of London, 8.30 P.M. Mr. Thomas Bryant, Lettsomian Lecture "On the Diseases of the Osseous System, and on Tumours, etc."—Royal Geographical.

TUESDAY. Royal Medical and Chirurgical Society of London, 8.30 P.M. Mr. Longmore, "On Two Cases of Kelis"; Dr. Robert Lee, "On the extent to which Human Life has been prolonged or abridged by Ovariectomy."—Zoological.

WEDNESDAY. Royal College of Physicians, 5 P.M. Dr. Pavy. Gulstonian Lectures. "On the Amyloid (so-called) and Fatty Degenerations."—Society of Arts.

THURSDAY. Royal.—Antiquarian.

FRIDAY. Royal College of Physicians, 5 P.M. Dr. Pavy. Gulstonian Lectures. "On the Amyloid (so-called) and Fatty Degenerations."—Royal Institution.

SATURDAY. Royal Botanical.

## POPULATION STATISTICS AND METEOROLOGY OF LONDON—FEBRUARY 14, 1863.

[From the Registrar-General's Report.]

		Births.	Deaths.
During week.....	{ Boys ..1092 Girls ..1016 }	2108	1346
Average of corresponding weeks 1853-62 .....		1986	1407
<b>Barometer:</b>			
Highest (Fri.) 30.502; lowest (Sun.) 29.829; mean, 30.170.			
<b>Thermometer:</b>			
Highest in sun—extremes (Fri.) 88.9 degs.; (Sun.) 55 degs.			
In shade—highest (Wed.) 42.1 degs.; lowest (Fri.) 29.7 degs.

Mean humidity of air (saturation=100), 84.			
Mean direction of wind, Variable.—Rain in inches, 0.09.			

## TO CORRESPONDENTS.

\*. All letters and communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen St., Lincoln's Inn Fields, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

THE LANCET AND SERVILITY.—The accusation of servility brought against the BRITISH MEDICAL JOURNAL by the *Lancet*, means simply this: that the BRITISH MEDICAL JOURNAL plays a slavish adhesion to the ordinary sentiments of honour and of courtesy, which are supposed to regulate the intercourse of gentlemen as well as of members of the medical profession.

AERIAL SCIENTIFIC ASCENTS.—The *Chemical News* tells us, in a lecture by Mr. Glaisher on the above subject, "that the scientific results of these ascents have been but small." The risk of life was great enough, at all events.

AN OLD ASSOCIATE.—The term "Baruria" means simply "heavy urine": that is to say, urine presenting a high specific gravity. The derivation of the word is *Bapros*, weight; *ὀύρον*, urine. The paper of Dr. Handfield Jones to which our correspondent refers, indicates to what precise conditions the term is applicable.

MR. NAPPER's letter shall appear next week.

THE LANCET AND DR. BURROWS.—SIR: As a member of the British Medical Association, I consider some steps should be taken to testify our abhorrence of the attack made upon our President by the editor of the *Lancet*. I think it must be obvious to all that such bitterness of spirit would not have been shewn, and certainly unnecessarily continued, had Dr. Burrows not been our President. This I consider the *Lancet* indirectly admits, when speaking of the President, the Editor, and the JOURNAL of the Association. It is needless for me to express my feelings with regard to the illiberal remarks uttered in the periodical before mentioned against Dr. Burrows, as I firmly believe the feelings of the whole profession are unanimous. In what manner these feelings can be best expressed to our excellent President, I must leave to others to decide. I am, etc., A MEMBER OF THE ASSOCIATION.

London, February 1863.

RUSSELL v. ADAMS.—The following is the verdict given by a competent tribunal—a jury of the defendant's own professional brethren—in the case of Russell v. Adams. On the occasion of the delivery of the Hunterian Oration last Saturday, at the Royal College of Surgeons, as the report runs—

"It deserves to be mentioned that as Mr. William Adams, Surgeon to the Orthopædic Hospital, the late defendant in an action, which terminated in his favour, and which is now considered a gross conspiracy, entered the theatre, he received quite an ovation."

TREATMENT OF ARMY MEDICAL OFFICERS.—The Horse Guards treats their medical men very much as they would the lower kind of the trading community. We understand that, *pour encourager les autres*, they make the medical officer who passes a recruit, defective in vision, liable for the payment of the value of the said raw recruit's kit!

MR. COULSON AS SHERIFF.—This is the first appointment of Sheriff made in the county of Cornwall by the Prince of Wales.

## SUBSCRIPTIONS.

THE following Laws of the Association will be strictly enforced:—

15. The subscription to the Association shall be One Guinea annually; and each member on paying his subscription shall be entitled to receive the publications of the Association of the current year. The subscriptions shall date from the 1st of January in each year, and shall be considered as due unless notice of withdrawal be given in writing to the Secretary on or before the 25th of December previous. If any member's subscription remain unpaid twelve months after it shall have become due, the publications of the Society shall be withheld from such member until his arrears be paid.

16. The name of no member shall remain on the books of the Association, whose arrears extend over three years; but the omission of the name from the list of members shall not be deemed, either in honour or equity, to relieve any member from his liability for the subscriptions due for the period during which he has availed himself of the privileges of membership.

PHILIP H. WILLIAMS, M.D., General Secretary.

Worcester, February 1863.

COMMUNICATIONS have been received from:—Dr. J. HUGHES BENNETT; Dr. J. MARSTON; Dr. E. T. R. TENISON; Dr. WILLIAM REDD; Mr. W. E. C. NOURSE; Dr. T. J. WALKER; Mr. J. VOSE SOLOMON; Dr. DOBELL; Mr. S. WOOD; Mr. GRIFFIN; Mr. HUGH NORRIS; Mr. J. SEAGWELL; Mr. WORKSWORTH; Dr. WILLIAM NEWMAN; Mr. H. GRAMSHAW; THE HONORARY SECRETARY OF THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY: Mr. JONATHAN HUTCHINSON; Dr. LIONEL BEALE; Dr. CROMPTON; Dr. JAMES RUSSELL; and Mr. T. M. STONE.

## BOOKS RECEIVED.

1. Illustrations of the Surgery of the Female Pelvic Organs. By H. Savage, M.D. London: 1863.
2. On Ringworm, Scald-Head, etc. By G. Ross, M.D. London: 1863.
3. The Twenty-Fifth Annual Report of the Suffolk Lunatic Asylum. By John Kirkman, M.D. 1863.
4. The Principles and Practice of Obstetrics. By G. S. Bedford, M.D. Third edition. New York: 1862.
5. Volumetrical Analysis. By Francis Sutton, F.C.S. London: 1863.
6. On the General Anatomy, etc., of *Limax Maximus*. By Dr. Lawson.
7. Memoir of Dr. E. Lyon.

**The Medical Register for 1863**

will be published on Saturday, 21st February, under the direction of the General Council of Medical Education and Registration of the United Kingdom, pursuant to an Act passed in the year 21 & 22 Vict., cap. 90, entitled "An Act to Regulate the Qualifications of Practitioners in Medicine and Surgery."

The MEDICAL REGISTER (price 4s.) can be had on application as follows:

LONDON.... Office of Medical Council, 32, Soho Square, W.;  
 EDINBURGH { Office of Branch Council, 28, Albany Street; or  
 Messrs. MacLachlan and Stewart, 64, South Bridge;  
 DUBLIN .... Messrs. Hodges, Smith, and Co., 104, Grafton Street;  
 Or it will be sent by post to any person applying for the same at any  
 of the above places, upon payment (per post-office order) of 4s. 10d.

**Royal College of Physicians.—**

The LECTURES of the present year will be delivered at the College, Pall Mall East, at Five o'clock on each of the following WEDNESDAYS and FRIDAYS.

**GULSTONIAN LECTURES.** Dr. PAYY. February 20, 25, 27. On the Amyloid (so-called) and Fatty Degenerations.

**CROONIAN LECTURES.** Dr. RISDON BENNETT. March 4, 6, 11. On some Points connected with Bronchitis, and its Results.

**LUMLEIAN LECTURES.** Dr. CHAMBERS. March 13, 18, 20. Formation of Mucus and Pus.  
 (By order of the President.)  
 1863. W. COPNEY.

**Solicitors.**

Messrs. BELT, STEWARD, & LLOYD.

**Secretary.**

JOHN MESSENT F.S.S.

By the peculiarly equitable manner of dividing the profits, the Policies issued by this Association become payable during the lifetime of the person Assured without extra Premium. After having been in force a period of five years, all Policies are absolutely Indefeasible and Indisputable.

Attention is directed to the facility afforded by this Institution for the Assurance of Declined or Diseased Lives. The experience of the large staff of Medical Officers connected with this Association has enabled the Directors to prepare a set of Tables which they believe place such lives on an equitable footing in relation to other assured Members of the Company.

Qualified Medical Attendants who are named by Proposers to this Association are consulted as the Medical Advisers of the Directors, by whom all Medical Fees are discharged.

Every description of Life Assurance transacted; terms for which, with detailed Prospectuses and every information, may be had on application to

JOHN MESSENT, F.S.S., *Manager and Secretary.*

*Applications for Agencies are invited.*

**WALTERS' INDIA-RUBBER URINALS.**

F. WALTERS having originally invented these Urinals, begs to warn the Profession of the many bad and useless imitations which are now sold, and he would advise them, before purchasing, to look that they are stamped with his name; as, unless that be the case, he cannot guarantee them.

These conveniences are made for those who require them only occasionally, during a long journey, as well as for those invalids who use them always. Mr. WALTERS has much improved them by making them of *Etherised India-Rubber*, which adds very greatly to the strength of the India-Rubber, at the same time that it prevents its sticking together; by this means he is enabled to make them less stiff and harsh than hitherto, and yet to retain all the advantages of that stiffness. There is a patent valve, which prevents the return of the fluid; and they may be worn either sitting, walking, or lying, without the slightest inconvenience, and without being perceived by any one.

WALTERS' CONVENIENCES FOR LADIES will be found particularly useful during pregnancy. They are perfectly soft and flexible, and may be worn with perfect comfort.

*All orders must be accompanied by a Post-Office Order or Reference. Entrance for Ladies, at the Private Door, where a Female attends.*

**MANUFACTURER OF ELASTIC STOCKINGS, BELTS, &c.**

16, MOORGATE STREET, NEAR THE BANK, LONDON, E.C.

## Remarks

ON

## THE MOLECULAR THEORY OF ORGANISATION:

IN REPLY TO DR. BEALE.

BY

JOHN HUGHES BENNETT, M.D.

PROFESSOR OF THE INSTITUTES OF MEDICINE, AND SENIOR PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF EDINBURGH.

I HAVE carefully considered the second communication of Dr. Beale, denominated "facts and arguments opposed to my theory of organisation"; and with every desire to arrive at such facts and understand the arguments, I can see little of either one or the other that bears on the subject. "I am not aware," says Dr. Beale, "of any observations by Dr. Bennett or by any other observer, which tend in any way to show that the ovum is formed by the coalescence of the molecules of the ovary, or that spermatozooids and germinal vesicles disintegrate to form molecules." On these points, I refer Dr. Beale to the writings and figures of Dr. Martin Barry, Meissner, Nelson, Keber, and others. I do not wish him to regard their expressed opinions or theories; but the facts they have observed, and some of which I copied in my first lecture in the *Lancet*—Figs. 9, 10, 13, 14, and 15. If my interpretation of these facts be wrong, would it not be better for Dr. Beale, instead of calling such statements vague, and affecting to doubt whether I mean what I have deliberately stated, to point out the error in detail, and describe how they are otherwise to be explained?

Dr. Beale says he can see no logical connexion between my sentences; that I combine ideas which are quite incompatible with one another, and make assertions so opposite to each other that both cannot be correct. I should have liked Dr. Beale to have pointed out more particularly in what manner I have thus offended. Although it is possible I may have expressed myself obscurely, I have not generally been accused of either speaking or writing unintelligibly. Besides, what I wish to impress upon Dr. Beale is that, even supposing him to be correct in these statements, they do not constitute either facts or arguments on his side adverse to my theory, as the title of his paper would lead us to suppose.

Again, may not Dr. Beale's avowed incapability of comprehending my views originate in the strong bias he possesses in favour of his own doctrines, in consequence of which he is unable to regard mine from an independent point of view? If so, he cannot be expected either to criticise or understand them correctly.

"If," says Dr. Beale, "the matter is in a state of solution when it comes into contact with the living mass, there can be no *juxtaposition of molecules*." I ask why not? How can solid matters grow or increase in extent and density, unless from that very solution solid molecules are thrown down which, by aggregation, produce bulk? I have given many observations in my first lecture where this was

seen to occur in viscous organic and inorganic fluids. What fact or argument has Dr. Beale advanced to refute them? Dr. Beale doubtless considers himself justified in thinking "that living matter must *always* increase in the same manner, and living particles must *always* multiply in the same way." But the reiteration of this opinion is no proof of its truth; still less is it fact or argument in opposition to my theory.

Dr. Beale has given a series of figures to show what no reasonable person will dispute; viz., that a minute body viewed with a magnifying power of 3000 diameters linear appears proportionally larger than the same body when magnified only 1800, 700, and 250 diameters. As an illustration of the utility of employing high powers, these figures must be regarded as unfortunate, seeing that no further information is to be derived from inspecting a large circle than from regarding a small one. I am quite prepared, however, to employ these high powers the moment Dr. Beale tells us he can by their aid see in molecules anything that has escaped previous observers.

Dr. Beale's figures of vibriones are quite correct, so far as the imperfect printing of his woodcuts will allow me to judge. He does not say that he has seen them in the act of dividing; and until he does so their supposed division must remain a mere opinion. He declares, however, that he can prove, by direct observation, that the smaller molecules do not coalesce or become aggregated to form larger masses. He also affirms that this process cannot occur in the case of particles so large as those figured by me. Now, if Dr. Beale can prove these statements, why does he not do so, instead of making affirmations? I am of the contrary opinion, and shall state the grounds from which it is derived. The question, however, is not whether molecules unite to form masses—although if a mass of molecules exist, it must be clear that they are aggregated together—but whether molecules unite to form the vibriones.

On making an infusion of flesh, and allowing it to putrefy, there will sooner or later appear, on the surface of the fluid, a delicate pellicle or scum. On examining this with a power of 800 diameters (which I have recently done, to satisfy Dr. Beale), it will be seen to present the structures figured below.

Fig. 1.—*a*. Structure of the scum on a putrid animal infusion on its first appearance. *b*. Structure of the scum six hours afterwards. The molecules separated. *c*. Structure of the scum on the second day. *d*. The same scum broken up. *e*. Filaments in the scum on the third and fourth days. (800 diameters linear.)

Fig. 2.—Presumed mode of developments of vibriones. 1. Primary molecules. 2. Larger molecules subsequently formed. 3. Aggregation of two molecules. 4. Their union. 5. Further coalescence of molecules producing vibratile filaments. 6. Still further aggregation, and coalescence of molecules in rows, to produce the highest degree of vibrional development. (800 diameters linear.)

The mode of development of the filaments, as derived from these appearances, is differently described

by Dr. Beale and myself. He says the molecules increase by absorption till they arrive at a certain size, and then divide. How he explains the formation of the filaments I do not know. But the molecules are formed first, and the filaments last; hence the latter must be produced from the former, in some way. To render my views intelligible, I have numbered what I conceive to be the different stages of growth; and I would ask Dr. Beale if, when the development has reached No. 2, the molecules divide, how it is the filaments can form at all. Surely a constant division of molecules at that period would be opposed to the formation of Nos. 4, 5, and 6. But it may frequently be seen that No. 3 is composed of molecules of exactly the same size as those of No. 2, which are floating loose—a fact in favour of the molecules coalescing, rather than dividing, as then they would be half their original size. My view, therefore, is, that the smaller molecules, although they may increase by imbibition of fluids, have yet a constant tendency to aggregate together and melt into one another. No. 3 is not a proof of No. 2 dividing, but of two molecules coalescing; and when they unite, they form No. 4. Two or more of these uniting form Nos. 5 and 6. When a similar process to this goes on in mineral bodies, as shown by Mr. Rainey, it cannot suggest division, but union; and this for the obvious reason, that the former would lead to disintegration; whereas it can be seen in one case, as in the other, that development is the result. In short, in the same manner as a tube is formed by a coalescence of cells, so is this minute vibratile filament formed by the coalescence of molecules. It may be argued, however, that each molecule elongates itself; that is, No. 2 is converted into No. 4; this into Nos. 5 and 6; and that No. 3 are sporules or ova, caused by the disintegration of No. 6. This view, however, is opposed by the fact that Nos. 1, 2, and 3 can be seen *before* Nos. 4, 5, and 6 are produced. Of this I have satisfied myself by frequent examinations of animal and vegetable infusions; and cannot, therefore, resist the conclusion that the development is such as I have described.

If, as Dr. Beale alleges, every one of my future lectures is likely to contain as many statements open to discussion as those which have appeared, it strengthens my conviction in the propriety of delaying further controversy until all are published. For although the task of criticism, as he thinks, would then be too great, I cannot help thinking that the labour of reply would be much diminished. Unless Dr. Beale, therefore, abandons generalities and assertions, and becomes more particular in his "facts and arguments", I cannot promise to continue the explanations to which he invites me.

**DISCOVERY OF SKELETONS.** A sensation has been created at Guildford, and for several miles round, in consequence of the discovery of five skeletons on a piece of land about a mile from Guildford. The skeletons were discovered by a man who has been trenching the ground and getting flints. They were each lying in a hole, or sort of rough vault, dug out of the chalk. On the breast of one was a dagger or knife. The bones were much decayed, but one of the skulls was in a remarkable state of preservation, as were the whole of the teeth. The skeletons have been examined by Mr. Ross, surgeon, of Guildford, who has given it as his opinion that two were old men, two middle-aged, and one a young man. The bodies were all lying east and west.

## Short Clinical Lectures

ON

## THE FIRST PRINCIPLES OF MEDICINE.

*Delivered at King's College Hospital.*

BY

LIONEL S. BEALE, M.B., F.R.S.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS; PROFESSOR OF PHYSIOLOGY AND OF GENERAL AND MORBID ANATOMY IN KING'S COLLEGE, LONDON; PHYSICIAN TO KING'S COLLEGE HOSPITAL; HONORARY FELLOW OF KING'S COLLEGE; ETC.

### I.—SOME OBSERVATIONS ON THE NATURE OF CERTAIN HEALTHY AND MORBID CHANGES, AND ON COUNTERIRRITATION.

*[Concluded from page 184.]*

COUNTERIRRITATION has nothing whatever to do with allopathy, or any other special system. It rests upon a principle which, I shall now endeavour to show, is thoroughly sound, and confirmed by some of the most recent and most exact observations.

Let us, then, consider how a blister applied to the skin can produce any beneficial effect in a case where a quantity of pus, mucus, and fluid, are being formed upon the surface of the mucous membrane of the bronchial tubes—in a case of chronic catarrh. I shall not discuss the effects of moxa, the actual cautery, and the more violent forms of counter-irritation, in this lecture.

As to the above morbid condition, we know—

1. That the vessels generally of the mucous membrane are congested; that it contains more blood than in the healthy state. The muscular walls of the small arteries are relaxed; the elastic capillaries distended with blood. Their thin, transparent, permeable walls, being stretched, are necessarily thinner, and more permeable to certain fluid parts of the blood. A greater quantity of soluble matters, therefore, escapes through the vascular walls than in a normal state.

2. Much of this increased quantity of fluid is taken up by the epithelial cells. The young cells especially, being supplied with a greater quantity of nutrient matter, grow faster. The masses of germinal matter (nuclei) increase, divide, and subdivide; and the process proceeds so rapidly, that there is no time for the conversion of the oldest outer portion into the formed matter corresponding to the wall of the cell, as always occurs in normal nutrition. A vast number of imperfectly formed epithelial cells and pus-corpuscles result. The more or less viscid material which surrounds these is all that represents the more hardened substance which forms the walls of epithelial cells generally, and gives to the healthy structure its characteristic properties and regularity of arrangement.

With regard to the influence of counterirritation, we must bear in mind—

1. That, generally, the afferent nerves distributed to the skin may influence, through the centre into which they are implanted, the efferent fibres distributed to the vessels of an organ lying beneath and perhaps at a considerable distance. It is possible, therefore, that the calibre of the small arteries dis-

tributed to the mucous membrane of the bronchial tubes may be diminished in consequence of the terminal network of afferent fibres distributed to the skin being influenced by the counterirritation.\*

2. In consequence of this contraction of the arteries, the walls of the capillaries would be relieved from the pressure of the blood; and, provided their elasticity was not permanently destroyed, they would recoil, and the blood they contained would be driven on to the veins. The effusion of fluid would be diminished. The cells would increase more slowly, and time would be allowed for the production of formed material (cell-wall) around each.

3. Crude matters in the blood may be taken up by cells which are multiplying with abnormal rapidity in any part of the body. Hence, when the cuticular cells are placed under conditions which facilitate their multiplication—that is, when they are supplied with an increased supply of pabulum—they grow very fast, and may separate from the blood materials which would otherwise form the pabulum of pus-cells that were multiplying upon the surface of the mucous membrane of the bronchial tubes. Thus, the increased nutrition in the latter situation would diminish while this state would be established in the skin.

Hence, counterirritation employed in such a case may act beneficially in two ways. First, by exciting through the afferent nerves in the skin an impression by which the efferent nerves distributed to the vessels of the mucous membrane are caused to contract, and thus a diminution in the supply of blood results; the direct consequence of this diminished supply of pabulum being a slower multiplication of the pus and imperfectly formed epithelial cells. In consequence of the increased flow of blood to the skin, the young cells of the cuticle grow and multiply at the expense of the pabulum, which would otherwise have gone to feed the structures formed on the surface of the mucous membrane. Secondly, such an increased action being established in the deep layers of the epidermis, crude materials in the blood, which would otherwise have been taken up by the pus on the mucous membrane, are appropriated here.

By giving diuretics and sudorifics in such a case, you promote increased action of the kidneys and skin, and the cells of these organs take up the crude pabulum, which has been accumulating in the blood; and thus, in another way, it is diverted from the mucous membrane of the bronchial tubes, and removed from the organism in the most rapid possible manner.

In this way the beneficial action of counterirritation may be explained.

But, if you have not permitted yourselves to be too much influenced by theoretical considerations, you will have felt inclined to say, ere this, "but counterirritation, applied directly to the skin or indirectly to the kidneys and other emunctories, is not the only thing to be thought of in the treatment of

an ordinary case of chronic bronchitis, where a quantity of secretion is being formed upon the mucous membrane of the larger and smaller bronchial tubes."

Nor will counterirritation always relieve permanently; for it not unfrequently happens that the discharge of sputum increases in spite of the application of a blister; and, as the blister, if kept open, often exhausts a patient, you know we have recourse to turpentine stupes (turpentine sprinkled on flannel which has been soaked in hot water and wrung out nearly dry), because we can apply them every day, and twice a day if we desire it, with much of the benefit and with none of the exhausting effects of a large blister.

There is then another point which, although not connected with the subject of counterirritation, is so important that it must never be lost sight of in the treatment of such cases. Just at this time of year, we have many cases of chronic winter cough in the wards, and of these the great majority would remain in the hospital for months, if we only acted upon the principle of counterirritation, and some of the patients would die. In these cases, we have to administer support, and frequently to give alcohol; but I shall postpone the consideration of this part of the treatment until I have discussed some points of interest in connection with pneumonia, as the principles upon which the beneficial effects of alcohol may be accounted for, and the principles which guide us in administering it in both these affections of the respiratory apparatus, are precisely the same.

**BEEES.** The *Agriculteur* contains the following remarks on these singular insects:—Bees do not pass the winter in a state of stupefaction, nor do they sleep much longer during that season than in any other; all that depends on the work they have to do. There are at all seasons some working bees alive and active in a hive, and at the time when provisions are being got in there are many at work day and night without taking any sleep at all. Their slumbers is very light at all times, for they sleep with their eyes open; the slightest noise, a vivid light, or a current of air, is enough to awaken them; but the warmer the hive is the easier it is for them to sleep. Hence they consume much less honey in a hive situated in a quiet place, little exposed to light and air, than in one more exposed. But if the outer temperature rises very high, this favours the laying of their eggs, and then a large quantity of honey is consumed. It is, therefore, easy to explain why in beehives placed close to each other the consumption of honey is different during winter, and this is a circumstance not to be neglected, because colonies which before winter seemed to have provisions enough to last them all through the month of March may be reduced to extremities before the end of January, in which case the agriculturist must come to their assistance. If the bees have been able to enjoy an excursion or two since Christmas they will easily partake of the liquid food, which may be offered them in a cup placed inside the hive, but if not, the food so administered may cause dysentery. To avoid this, honey-combs full of honey should be cut out of other hives where the supply is plentiful and transplanted into needy ones. This delicate operation is performed in a cellar, by the light of a lantern, and with the aid of smoke. The colonies thus assisted must be left in the cellar, if it be not too damp, until a fine day comes to allow of their flying out a little. The hives from which the honey-combs have been taken must also be left in the cellar for twenty-four hours at least, during which the bees feed on the honey that has exuded during the operation.

\* Even in the substance of fibrous and other tissues I have demonstrated numerous very fine nerve-fibres, which are independent of the dark-bordered fibres. The fine fibres above referred to are numerous in the fibrous tissues, even of the frog; and in tissues which contain truly sensitive fibres, they are also to be demonstrated. I believe them to be the afferent fibres of the sympathetic ganglia; the vaso-motor nerves distributed to the muscular coat of the small arteries being the efferent fibres of the same ganglia. (See papers on the "Ultimate Distribution of Nerve-Fibres", in course of publication in my *Archives*.)

## HOSPITAL PRACTICE:

METROPOLITAN AND PROVINCIAL.

BIRMINGHAM GENERAL HOSPITAL.

CASES OF RHEUMATIC PERICARDITIS.

Under the care of JAMES RUSSELL, M.D.

[Concluded from page 186.]

SINCE writing the preceding observations, two other cases of pericarditis have fallen under my notice, of sufficient interest to merit a brief record. The former of the two further illustrates the difficulty which may arise in discriminating between a rubbing sound and a valvular murmur. On more than one occasion in the foregoing cases, uncertainty has existed as to the nature of a particular sound, from the absence of anything sufficiently definite in the character of the sound itself. Expedients were employed to test its nature, whether pericardial or valvular, by noting its superficial position or the reverse, the extent of area over which it was audible, and the effect of pressure of the stethoscope in altering its character. But with every aid, it must sometimes happen that we are left in a state of uncertainty, and are reduced to waiting before we form a definite opinion.

In the following case, the occurrence of a very common complication, before the patient fell under our observation, nearly deprived us of any means of forming a diagnosis, excepting that which was afforded by the friction-sound itself; and we were then taught by experience that the evidence thus afforded may be very inconclusive.

CASE VIII. (Mr. F. H. Smith.) John Mears, aged 12, was admitted with pleurisy of the left side. The left side of the thorax was found perfectly dull, up to a line passing round the chest on a level with the seventh dorsal spine. The usual stethoscopic signs of pleurisy were present; but, in addition to these, a very distinct double sound, agreeing with the systole and diastole of the heart, was heard over the cardiac space. The character of the sound answered quite as much to that of a valvular murmur, as to that of a pericardial friction-sound; though plainly audible under the left clavicle, it was speedily lost on leaving the situation of the heart towards the right, and was scarcely distinguishable beneath the right clavicle, so far agreeing with a friction-sound; but, on the other hand, a systolic sound was distinctly audible over the posterior region of the left chest.

The history of the case did not afford any evidence of rheumatism, and justified the suspicion of the previous existence of valvular disease. Fortunately, however, for our diagnosis, the dullness occasioned by the pleuritic effusion did not reach a level sufficiently high to cover entirely the region occupied by a distended pericardium, which indicated its presence by a dull space bounded by a curved line, rising to the second rib, and descending across the sternum as far as an inch to the right of that bone.

In two days the effusion in the pericardium had greatly lessened, and the questionable sound then assumed a decided friction character; at the apex, on the contrary, a blowing sound developed itself more clearly, and in the course of a few days the presence of disease in the mitral valve, of old date, in addition to the pericarditis, was placed beyond a doubt by the discovery of coexistent hypertrophy of the heart.

The concluding case is one of *pyæmic* pericarditis. It occurred in the practice of my colleague Mr. Pemberton, who kindly permitted me to examine the specimen. Its interest lies in the confirmation which it affords to an opinion lately published by Dr. Kirkes (*Medical Times and Gazette*, October 25th), that in *pyæmia* pericarditis, when it occurs, is occasioned by so-called secondary abscesses in the tissue of the heart, strictly resembling in this respect the pleurisy which is often also present in the same disease. These deposits usually affect the surface of the organ, in which they are produced, and hence give rise to inflammation of the investing membrane, either by continuity of tissue; or sometimes by rupture, and the effusion of their contents into the serous sac.

The first case detailed in the foregoing series affords, with the following case, an interesting opportunity of contrasting two conditions which at first sight might seem analogous to one another, but which are in reality directly opposed. In the former case, undoubtedly, inflammation had affected the muscular fibre of the heart, having extended to that tissue from the pericardium. Here we find the *entire* superficial layer of the heart's tissue uniformly and equally affected, each ventricle also being implicated alike; in the case about to be detailed, on the contrary, isolated spots only were diseased, the intervening muscular tissue being healthy; and whilst the serous inflammation affected the entire surface of the heart, the disease of the muscular tissue was confined to the left ventricle exclusively. Again, by microscopic examination in the former case, a formation of celluloso-fibrous tissue and a copious deposit of fat was found to have taken place between the muscular fascicles, and appeared to have destroyed them by pressure; whilst, in the latter case, the fascicles were simply broken up, and their remains were intermixed with the *débris* of blood-cells.

This comparison at once establishes the totally different nature of the muscular affection in the two cases; and places the softened portions of the heart's tissue observed in the latter case in the same category with those present in the lungs, and with those which are frequent also in other solid organs, in cases of *pyæmia*.

I would also direct attention to the symptoms in the following case: presenting, as they did, a striking resemblance to rheumatic pericarditis in their apparent character, but widely differing from those usually manifested by that disease, in their tendency to early collapse, and in their rapid termination in death.

Mr. Bracey, the house-surgeon, has been kind enough to furnish me with a sketch of the history of the illness, from which the following report is abridged.

CASE IX. James Ward, aged 10, suffered a laceration of two fingers of his *right* hand, which rendered amputation of one finger necessary. The boy progressed favourably for three days, when he complained of pain in the *left* shoulder and upper arm; he had felt this pain before, and ascribed it to using his left hand in turning a windlass. The painful parts were swollen and reddened, and he complained when they were moved. Considerable feverish reaction rapidly established itself; his urine was scanty, and deposited a large amount of brown urates. In three days after the setting in of the symptoms, the physical signs of pericarditis were distinguished; the pulmonary sounds were normal. The boy had then become very feeble; his pulse was rapid and sinking, his heart's action tumultuous, his breathing quick and distressed, and his urine dark but clear. He died next morning.

The wounds were dark and inactive during the last illness, and did not discharge; nothing abnormal was noticed in the right arm.

SECTIO CADAVERIS. The entire surface of the heart was covered with a rather thin layer of soft lymph, most

abundant upon a portion of the *right* ventricle and at the base. On carefully scraping away this lymph, small irregular white patches appeared on different parts of the surface of the *left* ventricle, some raised like beads, others not projecting above the surface; two or three lay over the course of the coronary vessels, but the large majority had no relation to any vessel. These patches corresponded, each one to a small irregular cavity. The largest cavities were capable of containing a small pea, if reduced to a regular shape; some of these cavities were filled with a white puslike fluid, others with a pink pultaceous matter; their sides were very soft, and passed into the normal tissue by insensible gradations. I counted twelve of these cavities, and besides them there were also a few irregular dark livid patches, as if produced by ecchymosis. Most, but not all, were at the surface of the heart. None of them had undergone rupture; of this there could be no doubt. The coronary vessels were healthy, with the exception of one small branch, which was engaged in a cavity, and contained a puslike fluid.

One small ecchymosis was discovered in the tissue of the septum; with this exception the appearances now described were absolutely confined to the left ventricle. The pultaceous matter contained in the cavities, consisted of fine granular matter, and of irregular globules about 1-2500th of an inch in diameter; with these were intermixed *débris* of muscular fascicles, opaque, and without any appearance of striæ. In proportion as the patches were less softened, the remains of fascicles were more numerous, and in the ecchymosed patches the fascicles were distinct, and more or less deeply stained with blood. Around the cavities the muscular tissue presented its normal character.

Masses having all the appearance of pulmonary apoplexy were thickly scattered through both lungs, chiefly in the upper lobes; most were at or near the surface; their tissue was soft, but there was no appearance of suppuration. The other solid organs were perfectly healthy.

The joints of the left arm, the seat of the pain, were quite healthy, but considerable serous effusion had taken place into the cellular tissue around the elbow.

No disease could be discovered in any of the vessels; nor could any relation be ascertained between the morbid changes in the heart or lungs, and the branch of any vessel.

THE RELATIONS OF HEIGHT AND WEIGHT IN THE HUMAN BODY. In the *Statistical Society's Journal*, of March last, a very interesting table is given, showing the growth of the human body from eighteen up to thirty years of age, indicated by weight and height. The averages were taken from upwards of 4,800 observations at all ages. Thus, a lad of eighteen, if he be 5 feet 4 inches in height, speaking in round numbers, ought also to weigh somewhere about 8 stone 10 lbs. Given the age of twenty-one, and the height 5 feet 5 inches, he should weigh 9 stone 5 lbs. Ascending still further, and assuming the age to be twenty-five, and the height five feet 6 inches, the weight would be 10 stone 5 lbs.; and at thirty years of age, with a height of 5 feet 6 inches, we ought to have the result 10 stone 1 lb. In fact, so clear and demonstrable is this "law of increase in the growth of man," as determined by very extensive measurements taken at different times by scientific gentlemen, that we can almost work, as it were, in a rule of three sum any one condition we like. Taking the converse of what we have already exhibited, we may say that if a lad of nineteen weighs 9 stone 4 lbs., he ought to measure in height 5 feet 4 inches, and a little more; if at twenty-two, 9 stone 12 lbs., he should be 5 feet 6 inches in height, and so on. (*St. James's Magazine*.)

## Original Communications.

### THE LARYNGOSCOPE AND ITS CLINICAL APPLICATION.

By THOMAS JAMES WALKER, M.D.(Lond.), etc., Surgeon to the Peterborough Infirmary and Dispensary.

It was the late Mr. Liston, one of the most eminent of our British surgeons, who, more than twenty years ago, first suggested the use, in diseases of the larynx, of the instrument to which I wish to direct the attention of our associates; and the researches as to the physiological and pathological importance of the laryngoscope, pursued of late years with such good results in Germany and France, received their impetus from a memoir read before the Royal Society, published in 1855 in the *Philosophical Magazine and Journal of Science*, by M. Garcia, Esq., a resident in England.\*

Notwithstanding these facts, it cannot be denied that the great majority of medical practitioners in this country know little more of the laryngoscope than that such an instrument exists; and not a few were ignorant even of this fact, until the recent sojourn of Professor Czermak in London, and his demonstrations at several of the hospitals, were remarked upon in some of our weekly medical journals. Had the class of diseases, in the diagnosis and treatment of which this instrument yields such important aid, been constituted in this age of subdivision into a medical specialty, no doubt many medical men would have been found who, having persevered, and conquered without aid the difficulties which naturally attend the first efforts to employ an entirely new instrument, would have gladly made known by demonstration and otherwise to their brethren and to the public, that they were possessed of means which enabled them to treat with peculiar advantages that class of cases to which they specially directed their attention. The fact that the laryngoscope has not at once come into general use, will not be taken as an indication that it is wanting in practical value, by those who remember how long it was before the stethoscope made its way into the hands of the great bulk of medical men, or will consider how few there are among the members of our profession, who have made themselves sufficiently acquainted with the use of the ophthalmoscope to be able to employ it in practice, and yet its value in the diagnosis, and consequently the treatment of eye-diseases, is undoubted; and as regards this instrument, we must bear in mind that it is the subject of special courses of instruction, and that ophthalmologists have written treatises, by the assistance of which any one of us may understand its practical application. My own experience, however, with the ophthalmoscope, with which I in vain endeavoured to gain any useful information until I received from an accomplished master of its use a few practical hints, indicates, I think, the true reason why the laryngoscope is at present so little employed, although it might be readily applied with great advantage in cases which occur constantly in the practice of every medical man. It is, then, the want of clear practical directions as to the clinical application

\* This paper was sent up to the JOURNAL six months since; but, owing to unavoidable delay on my part in procuring the engravings, the publication has been postponed to the present time. Since it was written, Mr. Yearsley and others have pointed out that the late Mr. Avery had invented and constructed a laryngoscope in the year 1846. I purposely avoid entering into the controversy as to priority of invention and application of this instrument. I may mention that Dr. Merkel of Leipzig, in his work on *The Functions of the Pharynx and Larynx*, states that an artisan named Lelligues, a patient of Trousseau's, was the first to construct a laryngoscope, and used it on himself, about the year 1833.

of the larynx speculum which has led to its neglect; and it is this want which I shall endeavour to supply in this and subsequent papers on the same subject.

Having, during the summer and autumn of 1860, availed myself of the opportunities afforded during a sojourn in Vienna, to observe the practice of Stoerk, Semeleder and others, and having since that period been in the habit of employing the laryngoscope in my daily practice, I can confidently state that the difficulties spoken of by those who are practically unacquainted with the use of the instrument, are in a great measure chimerical; indeed, at this moment I cannot recall a single case of laryngeal disease in which I have wished to avail myself of the instrument, and have failed to obtain a view of the part affected. Let the practitioner persevere until he has learned to illuminate the pharynx, and hold the mirror in such a way as to display the larynx in the most tolerant of subjects; and he will then find that no more than very ordinary skill on his own part, and no extraordinary steadiness on the part of his patient, are requisite to his acquiring most valuable information from the laryngoscope in pathological cases. I have alluded to the stethoscope and the ophthalmoscope in comparison with this instrument; I may now state, that accurate observations may be made with the laryngoscope, with an exercise of far less study and far less skill, than that required by either of the former instruments. With this encouragement to those who, following the directions I shall give, will endeavour to explore these regions which have hitherto been hidden from our eye, I shall proceed at once to describe, first shortly, the principles of the laryngoscope; secondly, the instruments we employ; thirdly, the appearance of the normal parts when viewed by aid of these instruments; fourthly, the exact mode of applying the instruments, directions for which will be much more intelligible after the laryngeal image has been described than earlier; and lastly, I shall give cases illustrative of the pathological conditions in which these instruments are of value.

#### I.—PRINCIPLES OF THE LARYNGOSCOPE.

The principles on which the laryngoscope is constructed and applied require but little explanation; they require for their comprehension no complex knowledge of optics; the only law that we must bear in mind being that when a ray of light is reflected from a plane surface, the angle of reflection is equal to the angle of incidence. A small mirror mounted on a long handle, having been previously warmed in order that the watery vapour expired from the lungs may not condense upon it, is held in the pharynx on a level with the soft palate, in such a position that the rays of light which it receives through the open mouth are reflected down into the larynx and trachea. An image of the parts so illuminated is formed in the same mirror, and is seen by the eye of the observer placed opposite the mouth, without the aid of lenses or any other medium. This image, of course, appears to be placed at the same distance behind the mirror as the object reflected actually is in front of it; and it is of the greatest importance when we are making and recording our observations in pathological cases, that we should remember that the image represents the parts in an inverted position. Although I should have imagined that any one giving the subject the least consideration would have comprehended at once the relation between the various parts of the larynx itself and of its reflection in the mirror, there appears so much confusion in the writings of some of the foreign laryngoscopists, that I introduce the accompanying diagram to make the matter clearer.

If the mirror were held in a vertical position at the back of the throat, the image of the larynx would be inverted antero-posteriorly, and the most anterior part of the larynx, the epiglottis, would be the furthest from us in the image; but, with the mirror in this position, the

image would be out of the view of the observer. If, again, the mirror were held horizontally, an equally impracticable position, an image would be formed, in which the epiglottis would be immediately over the true epiglottis at the most anterior part of the image, and the arytenoid cartilages immediately over their actual position

Fig. 1.—A. Anterior view of larynx; a. Epiglottis. B. Opening of larynx as inverted in mirror; a. Epiglottis; b b'. Arytenoid cartilages; r and l. Right and left vocal cords.

at the hindmost part of the image. The mirror being held, however, in a position intermediate to these, an image is formed in which the parts, instead of being arranged from before backwards, are seen in a vertical plane; the most anterior part of the larynx, the epiglottis (a), being at the highest part of the image, and the arytenoid cartilages (b, b') being the lowest. The antero-posterior version that is talked of does not, therefore, actually take place; and certainly, as we pass the mirror back into the fauces, the parts come into view as they are situated in the larynx, the epiglottis first, and then the other parts in the order in which they lie, back to the arytenoid cartilages. The lateral inversion is that which requires most consideration; but it will, I think, be at once intelligible on reference to the diagram, in which a represents the larynx under observation, B the image of the same as formed in the mirror. Now, r the right and l the left vocal cord, are seen on the right and left sides of the mirror exactly opposite to their true position (that is respectively on the left and right hand of the observer); but r, the true right vocal cord, is the left, and l similarly is the right vocal cord of the image, as we see if we turn the diagram upside down, and look at the image B as though we were looking at the front of the larynx and epiglottis; that is, if we suppose the image to be placed in the same position as the larynx A. The same inversion of course takes place of the right and left aryteno-epiglottidean folds, of the right and left arytenoid cartilages b, b'; and of all other lateral parts of the larynx. An ulcer or any other morbid appearance situated on the left vocal cord (l) of the larynx (A) appears to be on the right vocal cord of the image (B), although of course it is situated on the same side of the mirror as of the larynx under examination.

It is, I think, the confounding the position of the parts in the mirror with their position in the image

which has led to the confusion in the description of the relations between the larynx and its image to which I have alluded. Experience is necessary to enable us at once to correct the false representation given in the mirror; but with this experience, we make the necessary corrections with almost as little consciousness of mental effort, as when we mentally convert the inverted image which is formed upon the retina into the true representation of the various objects which surround us in every day life.

## DIPHTHERIA.

By WM. NEWMAN, M.D. Lond., St. Martin's, Stamford.

HAVING already given to the readers of the BRITISH MEDICAL JOURNAL, (September 14th, 1861) a statement of those cases of diphtheria which had occurred in my practice—then at Fulbeck, near Grantham—in the first six months of 1861, I wish now to lay before them the series noted in the second half of the same year. And I do this with the hope of some resulting good; since the instances thus put upon record, being the product of a widely spread agricultural district, offered to the same observer, subjected to the same external influences, and modified by an unvarying plan of treatment, may be supposed to exhibit a fair record of the disease throughout a year of its ordinary history.

Sex has little influence. Of the patients, ten were males, and eight females.

Age. The ages of the patients are shewn in the subjoined table:—

Age.	Number of cases.	Per cent.
0 to 5 .....	1 .....	5.55
5 to 10 .....	1 .....	5.55
10 to 15 .....	3 .....	16.66
15 to 20 .....	4 .....	22.22
20 to 25 .....	1 .....	5.55
25 to 30 .....	3 .....	16.66
30 and upwards ....	5 .....	27.77
	18	99.96

Mortality. There was one death in 18; or 5.55 per cent.

In the data of age and mortality, the cases now noticed stand in almost direct opposition to those given in my last paper. The causes of this difference will be noticed further on.

To some of these cases, I would draw more direct attention; they are of interest, as much from individual peculiarities as from their combined value.

CASE II. This was the only fatal one in the series—fatal, too, from direct affection of the larynx; death resulting within twenty-four hours. But for due examina-

tion of the throat, the case would have been looked upon as one of ordinary croup. There had been no history of prior illness, no failure in general power, until the clanging cough and stridulous breathing were noticed; yet there was enlargement and soreness of the submaxillary glands, and the *débris* of very well marked exudation on the uvula and tonsils.

If the writings of French physicians be consulted, they tell us that croup is, with but very rare exceptions, the sequel of, and dependent upon, pharyngeal diphtheritic deposit—a matter, in short, of local extension. This is the sole case I have seen tending to bear out this view.

CASES III and v. Both derived their affection from the same source. In both cases the local deposit and suffering were but slight; yet each of them had very characteristic depression and constitutional disturbance. Coincident inflammation of the parotid gland only on one side was also present.\* Case III was well in three weeks or less. Case v was much more tedious in convalescence. The whole system was unbinged, and strength was very slowly regained by free administration of tonics and abundant supply of food. Six months later, a large abscess, with deep burrowing sinns, formed in the upper and inner part of the left thigh. I am strongly disposed to connect, certainly the severity of this local affection, if not indeed absolutely, its occurrence with the extreme debility consequent upon the throat-disorder.

CASE VI. Local œdema and very rapid and abundant appearance of exudation were here noted. The man's state was for some days very precarious; and, though prior to this illness an athletic powerful man, he was very seriously prostrated. No nervous sequelæ showed themselves.

CASE VIII presented partial loss of power in both lower extremities, sensation being more damaged than motor power. Some time passed over before this symptom disappeared; the throat-disorder having, however, been far from severe.

CASE IX. I had seen, as reported in my last paper, one instance of secondary abscess in the neck. In this person abscess formed, three or four days after the exudation had cleared away, in the soft palate; and attained such a size as to produce very great inconvenience both in respiration and deglutition. The subsequent recovery, after the discharge of the pus, was rapid.

CASE X is noteworthy, from the coincidence, almost from the very commencement of the throat-malady, of excessive sickness; no matter what was taken, it was immediately rejected. I could but trace its existence to some irritation of the par vagum. Internal remedies seemed of little or no avail; external counterirritation was certainly of some service.

But little of especial interest is attached to the other cases.

The rates of mortality noted in the two series of cases—1 in 5, and 1 in 18—differ widely enough; admitting, however, of easy explanation on reference to certain conditions.

a. Age. The majority of those reported on the last occasion were young children, having proportionally little vital power, and therefore succumbing rapidly to any form of blood-poisoning. On the other hand, most of those now mentioned were over fifteen years of age.

b. Varying Conditions of Access. In the earlier instances, in 23 out of 35, the disease was endemic, with a resulting mortality of 1 in 4.3; while, in the present group, the affection was uniformly sporadic.

These conclusions may, on the whole, be fairly drawn.

The severity of diphtheritic affections, and indeed

\* A case of this kind was reported by Dr. Gibb to the London Pathological Society. (*Medical Times and Gazette*, Feb. 18, 1862.)

their duration also, stand in inverse ratio to the vital power of the patient. The mortality is in inverse proportion to the age of those attacked by the disease.

With regard to treatment, our efforts should be directed—

1. *To prevent the early access of exhaustion.* I have named this as one especial point, in order thereby to place very much stress on the necessity of thorough rest: for the adult, rest mental and physical; for the child, enforced abstinence from movement as far as possible. I have seen repeatedly increase of local mischief after even slight exertion, and nausea and faintness readily supervene. In all cases where it can be done, the recumbent or semirecumbent posture should be maintained; and the sufferer sedulously waited on—not even in trifles allowed to attend to his own comfort.

2. *To uphold and increase general power.* To this end, the room should be well ventilated by direct entrance of fresh air, if the season will allow of it; if not, then a good fire, with care in preventing direct draught, but in no case shutting up the patient either with antiquated close-drawn curtains or in an ill-ventilated room, thus allowing him to breathe over and over again air vitiated by the ordinary products of respiration and the special organic impurities of the disease.

Abundant and frequent supplies of nourishment should be given: meat, in whatever form it can best be taken; and stimulants. Perhaps, of these, port wine is best; next to it, brandy and water. By some patients, malt liquor is better taken. But yet I would make this the cardinal rule: give food from the first. The disease has a time when nourishment will not, cannot be taken; and, unless liberal supplies have before this been given, the patient will of necessity sink.

As diphtheria answers, in very many of its characters, to the type of a blood-disease, those remedies are most indicated which tend to improve the circulating fluid: the preparations of iron as a whole, specially, and perhaps in a measure from its local influence, the tincture of the sesquichloride has appeared to me to answer best. I have not unfrequently given it in combination with chlorate of potash, or with quinine. Some, who cannot take iron well, will derive advantage from the compound tincture of bark with hydrochloric acid. Ammonia has seemed to me to be of doubtful efficacy. Emetics, depressing remedies, and mercurials, have still their advocates; but neither from what I have seen, nor from the reported cases, should I be disposed to resort to the use of these agents.

3. *To arrest the local affection, and bar its extension from foci already existing.* The very common application of the nitrate of silver, I have little trust in. Its effects are not sufficiently marked in the clearing away of existing deposit, or in the prevention of its recurrence; while the white coating consequent on any free use of the salt materially obscures the condition of exudation. In the more severe cases, where there is much coincident and surrounding redness of tonsils and uvula, I would once freely apply the hydrochloric acid. As a subsequent application, or indeed as of primary advantage, I have had reason thoroughly to believe in the efficacy of Beaufoy's chloride of soda, used undiluted with a large camel-hair brush two or three times a day, and more frequently as a gargle made up with glycerine and water—one part to six or eight parts of water. This application I learnt last year from Dr. Budd's comprehensive paper (BRITISH MEDICAL JOURNAL, June 1st, 1861), and each succeeding case makes me more confident in its power as a local agent.

I would close my paper by urging the propriety of the medical attendant personally, so far as he may, applying these and other local remedies, and also seeing to the thorough carrying out of the plans for giving medicine and food. In this disease there is no time to be wasted.

Bad nursing will destroy many a sufferer; and remedial means powerful enough for good will prove simply nugatory, if inefficiently used.

## CASE OF FATTY HEART.

By E. T. R. TENISON, M.D.

I THINK the following case worthy of notice, showing, as it does, how most serious heart-disease may exist without any marked disturbance of the circulation or respiration, or exhibiting, save in a very mild form, the symptoms usually accompanying cardiac affections.

On the 25th December last, I was hastily summoned to see Isaac Hoare, aged 57, living at Starch Green. He was reported to have "choked himself" by a morsel of food "going the wrong way." I found the patient in profound collapse, covered with cold sweat; respiration was performed by gasps, with long intervals between each breath; he was pulseless as high up as the axilla. On being placed in the horizontal position, he died without a struggle. On inquiry, I learned that the deceased had suffered fourteen years ago, from "inflammation of the chest," which confined him to bed five weeks, and from which he slowly recovered. Since that time, he had been unable to lie, save on his back, without an uneasy sensation, amounting sometimes to pain, referred to the heart; this being more annoying when he attempted to rest on the left side. Otherwise he made no complaint, seeming to enjoy good health, and being able in all weathers to pursue his ordinary work as a road-labourer. On sitting down to dinner on the 25th, he appeared as well as usual; but almost immediately afterwards fainted. I saw him a few minutes later, and found him as described above. I may mention here that the brother, sister, and son of the deceased all died suddenly; and, as far as I could make out, of heart affections.

*Post mortem examination*, eighteen hours after death. The larynx and trachea were, as I expected, quite free from any foreign body. The muscles of the chest were pale and covered with fat. Some old but unimportant pleural adhesions existed; but the lungs were healthy. On opening the pericardium, I found that cavity filled with dark coloured fluid blood. The heart was almost converted into fat; and a rent three-fourths of an inch long occupied the posterior portion of the apex of the left ventricle, from which no doubt, the blood contained in the pericardium had escaped. Besides this, the walls of the heart were thinned, especially those of the ventricles; the muscular structure was pale, greasy, and easily torn. The valves were healthy; except the aortic, which permitted some regurgitation. The ascending portion of the arch of the aorta contained several patches of atheromatous deposit.

**INFLUENCE OF OZONISED AIR UPON ANIMALS.** Dr. Ireland says: "These experiments were most carefully performed, and all sources of complication avoided as carefully as possible; and, as I felt satisfied of their correctness, I saw no reason to sacrifice the lives of more animals in repeating them. I submit to the reader the following conclusions:—1. Ozonised air accelerates the respiration, and, we may infer, the circulation. 2. Ozonised air excites the nervous system. 3. Ozonised air promotes the coagulability of the blood, probably by increasing its fibrine. In the blood, however, ozone loses its peculiar properties, probably entering into combination with some of the constituents of the circulating fluid. 4. Animals can be subjected to the influence of a considerable proportion of ozone in the air for hours without permanent injury; but in the end ozone produces effects which may continue after its withdrawal and destroy life." (*Edinburgh Med. Jour.*)

## Reviews and Notices.

LECTURES ON SURGERY, DELIVERED IN ST. BARTHOLOMEW'S HOSPITAL. By WILLIAM LAWRENCE, F.R.S., Serjeant-Surgeon to the Queen, and Surgeon to the Royal Hospitals of St. Bartholomew and Bethlem. Pp. 632. London: 1863.

THE publication of these *Lectures*, we learn from Mr. LAWRENCE'S preface, was not undertaken by him without some reluctance; and it was only at the request of, and in consideration of an offer of aid from, his friend and colleague Mr. Holmes Coote, that he was induced to enter on the task. Before, however, the work had proceeded far, Mr. Lawrence "discovered that an undertaking like the present must be the work of one person"; and, therefore, he hastens to disburden Mr. Coote of any responsibility.

"In order to relieve him from responsibility in respect to any opinions or statements in which he may not coincide, it is right to mention that he neither saw the greater part of the manuscript before it went to the printer, nor has seen a single page in print before the publication of the book. I take this opportunity of thanking him sincerely for his ready and kind offer of cooperation on this, and for his valuable services on many other occasions."

That any attempt at literary cooperation between Mr. Lawrence and one of his younger colleagues should be found impracticable, is not surprising. To render it possible, one of two things must occur: either the senior must exhibit an amount of perseverance, and a capability for following up the numerous advances and changes in his art, very rarely to be met with in a man of Mr. Lawrence's years; or the junior must put himself back a quarter of a century or more. This, we take it, is the true state of the case: Mr. Lawrence could not go forward to the advanced views of Mr. Coote; Mr. Coote could not go back to accept, without question or qualification, the doctrines of Mr. Lawrence. No blame lies with either; on the contrary, they have acted sensibly and honourably in dissolving a literary partnership which was impracticable.

We have, then, Mr. Lawrence alone responsible for these lectures; and, from the observations made in the preface, we should not expect to find in them such an exposition of modern doctrines as is met with in most of the surgical works which have appeared within the last few years. A comparison of things of the past with the present confirms this opinion. Much of the present volume is identical in order and sentiment, and all but identical in expression, with a large portion of a course of lectures by Mr. Lawrence published in the *London Medical Gazette* for 1830. Here and there, indeed, notices of more modern scientific researches, and additions of practical importance from the stores of the author's large experience, are introduced; but still the basis of the lecture lies there, where we have indicated.

The reader of Mr. Lawrence's book must not, then, expect to find in it all they would look for from Syme, Paget, Erichsen, Miller, and other such men of the present time. He must take up the book as the work of a practical man, a worthy successor in his hospital of Pott and Abernethy; one who, more than thirty years ago, was able to put forth his

views on surgical matters in such a form that even now, brought forward in a new guise and with some addition, but without essential alteration, they may instruct many.

The book commences with an Introduction on the Distinction between Physic and Surgery; in which, as in 1830, Mr. Lawrence expresses a distinct and forcible opinion in support of the unity of medicine.

"To assert", he says, "that surgery and physic are essentially distinct, is to say that there are two kinds of pathology; that the external and internal parts are to be treated on different principles. It would be as rational to say that there are two kinds of physiology, one for the outside, the other for the inside of the body. When you know that the component tissues, or organic elements of our frame, are the same throughout, can you suppose that the position of a part in the body can alter the nature and treatment of disease? It may cause differences in the mode of proceeding; thus you have less power of acting locally on internal parts; it may make the pathological investigation of one organ more difficult or easy than that of another; but it cannot alter essential principles. Inflammation, for instance, is the same kind of disturbance, whether in an external or internal part; and we treat it exactly on the same principles, whether it be in the eye, breast, or testicle; in the heart, lungs, or liver. The principles of pathology, therefore, are general; they are the same for all parts of the healing art. They result from our knowledge of health and disease generally, and must, therefore, be common to the physician and surgeon."

Again, after pointing out that the best preparation for a physician is the study of surgery—that is, of external diseases—he says:

"I consider a comprehensive acquaintance with medicine equally necessary to those who mean to practise surgery only. If the surgeon is to rank higher in public estimation than the general practitioner, will he rest his claim to this superior dignity on the circumstance of possessing a lower amount of medical knowledge? It is necessary that surgeons should apply, in their own department, the principles and modes of relief deduced from a survey of medicine generally. The manual part of surgery is far less important than the medical; and it would be indeed disgraceful to our profession if surgeons were not competent to the management of surgical cases without the assistance of any other practitioners."

The Council of the Royal College of Surgeons would do well, we think, to study and act on the sound doctrine which has thus been enunciated by one of the most eminent members of their body.

The body of the work consists of twenty-two chapters; viz.: 1. The Nature and Divisions of Disease; Arrangement and Classification; Nosology; 2, 3, and 4, Inflammation; 5, Spontaneous Inflammations, and the Unhealthy States of Constitution to which they owe their Origin; 6, Fever; 7, Suppuration; 8, Chronic Abscess; 9, Ulceration; 10, Mortification; 11, Wounds; 12, Poisoned Wounds; Hydrophobia; Venomous Serpents; Dissection Wounds; 13, Scalds and Burns; 14, Sympathetic Effects of Local Injuries; 15, Scrofula; 16, Gout and Rheumatism; 17 and 18, Syphilis; 19, Gonorrhœa; 20, Cancer; 21, Fungus Hæmatodes; 22, Melanosis.

This list consists mostly of subjects which are generally recognised as belonging to the medical rather than to the operative aspect of surgery; and they are subjects, too, on the nature of which investigation has been directed with the greatest energy during the last twenty or thirty years. Our readers

will perhaps now better appreciate the remarks we made in an earlier part of this notice, when we intimated that they must look for the practical rather than the scientific in Mr. Lawrence's book. The author has in his day done his share in the advancement of his science; and therefore we look on this work of his with respect, and with a feeling of gladness at seeing him again among us, albeit his dress be not of the most modern and approved fashion.

CHINA FROM A MEDICAL POINT OF VIEW IN 1860 AND 1861. By C. A. GORDON, M.D., C.B., Deputy Inspector-General of Hospitals, etc. Pp. 464. London: 1863.

DR. GORDON accompanied the late expedition to China, and had a favourable opportunity of observing the climate, manners, and diseases of one or two localities in that vast empire. These observations he now lays before the public and the profession; we say the public as well as the profession, because the matter contained in his volume cannot fail to be of interest and instruction to all classes of readers.

Dr. Gordon evidently made good use of his time while in the Celestials' country. Notwithstanding the onerous duties which fell upon him in his official capacity, and the villainous nature of the climate, he seems to have seized upon every occasion of making himself well acquainted with the manners and customs of the natives amongst whom he was, by his duties, temporarily thrown. His volume, therefore, whilst containing a large amount of valuable medical details and statistics, also contains a large amount of matter which will be found, as we have said, full of instruction to the general reader.

Dr. Gordon reached Hong Kong in June 1860. From thence he goes to Canton. Afterwards, he voyages on from Hong Kong up the Peiho to Tein-tsin, which he reached on December 16th, and where he remained until October of the following year. The greater part of his volume is, therefore, naturally occupied with a description of his experience of men and things as observed at Tein-tsin.

We need hardly recommend this volume to those of our medical brethren whose fortune or misfortune may bring them into these regions of the Celestials; for assuredly no wise medical man would depart thither without making himself master of the valuable lessons to be gathered from Dr. Gordon's experience, respecting hygiene, climate, diseases, etc. But we would also strongly recommend the perusal of this volume to those of our brethren whose avocations are not likely ever to draw them outside the limits of their daily routine of practice. They will gain pleasure, instruction, and profit from the perusal.

In his first chapter, Dr. Gordon gives an historical notice of China. In the second, he treats of Hong Kong. In the third, of Canton. In the fourth chapter, he takes us from Hong Kong to Peiho; and in the fifth, reaches Tein-tsin. Here he remains, and of the place discourses fully—of the people; of the topography; of the zoology; of the climatology; of the hygiene and of the mortality of the troops at Tein-tsin, British and Native-Indian; and one chapter is devoted to the "pathology of diseases there."

It is, of course, impossible for us to follow the Doctor through these pages; but we may give the reader a few extracts from them to show what kind of information he may expect to find within, and how that information is imparted.

The "people" of Hong Kong he speaks of as energetic and active.

"In many respects the labouring classes at Hong Kong contrast favourably with the corresponding classes in Britain. In personal cleanliness they are certainly superior to the 'great unwashed' of our towns, and even of the agricultural districts. In quiet industry they beat the Englishman hollow. In propriety of demeanour, and in sobriety of habits, the contrast between the Chinaman and our own sailors and soldiers may be seen at Hong Kong at almost any hour of the day, and until a late hour at night." (P. 27.)

Small-pox, he tells us, plays havoc with the Chinese. He says:—

"Small-pox is also very prevalent, making terrible devastation among eyes, and leaving scars that are horrible to look at upon the faces of its subjects. As elsewhere stated, vaccination is not practised by the Chinese, but in its stead inoculation. The consequence is that the scourge small-pox is disseminated by art, in addition to the periodical visits it makes in an epidemic form. But these are not all the circumstances that aid in the production of blindness among the people in the north of China. A favourite method of treating diseases affecting the eyes consists in scraping the inner surface of the eyelid, which process is performed by a class of men who make this branch of native surgery their particular province. The result of the operation is that the eyelid becomes inverted, so as to bring the eyelashes in contact with the point of the eyeball itself; disease is thus induced, and after a short time the power of sight becomes destroyed." (P. 122.)

The practitioner of medicine at Tein-tsin is naturally an object of interest to us. Here he is as engaged in action:—

"At a retiring and comparatively quiet corner of the principal business street, this professor of the healing art has taken up his quarters. These quarters consist of an awning of blue cotton cloth, with white borders, upon which, in Chinese characters, are described at length the wonderful accomplishments of the presiding genius. The awning is extended upon four upright poles, so that secrecy cannot be observed here; not that this signifies much, for the Chinese are not naturally a modest race, and an artificial civilisation has not done a great deal to render them so, even to external appearances, as it is said to be the case in some western nations. The patient, accordingly, boldly walks up to the physician here, for none who are so ill as to be unable to walk ever seem to ask for medical advice. Here he relates his various ailments, and it may be some of the idlers who are to be met with upon the streets, close in to listen to his recital of bodily ills. There is equally little mystery about the examination by the Chinese *Æsculapius*, or about his prescription. A number of small phials filled with gilded pills, some pieces of a black-coloured plaster, and any number of old decayed stumps of teeth, are strewn about upon the table." (P. 125-6.)

The chapter on the Hygiene of Tein-tsin is a very interesting one. It tells us how the health of our troops was there watched over; and is full of valuable hints for the future resident there. He remarks here that "much has been said of late years of the supposed propriety of assimilating the hospital system of the British army to that of the

French." There was, he adds, plenty of opportunities of comparing the two systems; and, as the result, we are told that the "French officers, on reading our regulations, one and all expressed their sense of the superiority of our system to theirs." So it is not in all particulars that they manage these things better in France."

The twelfth chapter contains an account of a hospital opened in China for the benefit of the Chinese, and of its great success. One striking fact was noticed—the apparent want of sensibility to pain of the Chinese.

"A large proportion of those upon whom operations were performed had no chloroform given to them, and these, unless when the operation was more than usually protracted, neither cried nor winced; some did not even clench their hands or teeth, but lay upon the table perfectly motionless, while their muscles were being cut by the knife, and their bones divided by saw, forceps, or gouge.

"That this may be in some degree attributable to the circumstance of the sensibility of the nervous system being less acute in the Chinese than in the European is quite probable. That this is so, is mere matter of speculation; but were it an actual fact, it would be insufficient to account for the great degree to which indifference of pain is observable among them; a good deal is, therefore, no doubt due to moral training. From their earliest youth the Chinese are taught indifference to bodily suffering, or to life itself. Personal cruelty is instilled into their nature from their infancy; and so effectually, that I have seen bystanders and relations of a subject of operation smiling and joking as its details were being proceeded with, and I have seen a person just removed from the operating table, and placed for the time being upon a bed in the immediate vicinity, smile at, and appear to enjoy the agonies of his successor, as the knife was cutting its way through, and the blood trickling from his quivering flesh." (P. 430.)

The concluding chapter tells of the joy of the writer to escape from "that most filthy of filthy Chinese cities Tein-tsin," and of an almost romantic journey to Nagasaki, a Japanese port, where the vessel that bore him touched to take in coal.

LUNACY MURDERS, ETC., IN NEW YORK. Two suicides and one homicide were reported on one day as occurring at the hands of persons who have been recognised as of unsound mind, but who have been allowed at large. The first was the case of John Fitzgerald, a wealthy banker of Wisconsin, who came to this city for his health. One member of his family had died in a lunatic asylum, and he, fearing that he might become insane, had threatened his own life. He retired to his room at the St. Nicholas, and, after writing letters to his wife and friends giving instructions as to his burial, deliberately shot himself. The second case occurred at the Sailors' Snug Harbour, Staten Island. An inmate of that institution, named Ingalls, had been reprimanded for swearing by the chaplain, the Rev. Mr. Quinn. At this the sailor seemed to become alarmed lest he should be exposed for what he called "that horrible affair." He importuned the chaplain not to expose him, but the latter made light of his alarm, attributing it to a slight aberration of mind. On the morning of the murder Ingalls was noticed to act strangely. On leaving the institution after services on Sunday, the chaplain met the sailor, who said, "You will expose me, I know you will, if you live," and drawing a double-barrelled pistol from his breast first shot the chaplain dead, and then discharged it at his own head, inflicting a fatal wound.

## Progress of Medical Science.

### REMOVAL OF THE WHOLE OF THE SHAFT OF THE FEMUR.

Mr. Beane, Surgeon to the Melbourne Hospital, relates the following case:—The patient, aged 21, had always had good health. In October, 1860, he walked a short distance after dinner on a wet day, but did not get wet. He sat down for a short time in a room, when, feeling cold, he went to the fire. He then felt pain in the leg near the knee, and walked lame. The lower part of the thigh began to swell, and the swelling gradually extended up the thigh; he had fever, with symptoms of inflammation of the bowels, and sweated profusely. At the end of six weeks, matter formed near the upper part of the thigh, and two or three weeks later a large quantity escaped. Other collections of matter ensued, and broke. The openings formed continued to discharge. The thigh-bone was very much enlarged, but the enlargement was most marked near the upper third; here he suffered from a dull aching pain; the pain had been very severe, relief following the escape of some thick yellow matter. The leg was twice as large as the opposite one; the skin, cellular tissue, muscles, and bone being united together. There were seven or eight openings—three or four very large ones—some discharging whey-like fluid, others thick pus. He had not had night sweats since the leg began to discharge. He had gained flesh during twelve months; his appetite was good, tongue clean, pulse 78, and lungs healthy. No diseased bone could be felt through any of the sinuses.

Amputation of the thigh had been advised by several surgeons; but feeling convinced that the case was one of acute inflammation of the shaft of the femur, followed by its death and the formation of a casing of new bone, Mr. Beane determined to cut through the new bone and remove it. On the 24th of January, 1862, he was placed under the influence of chloroform; a semi-circular incision was then made in the centre of the outside of the thigh, and the flap thus made dissected from the bone. By means of a strong gouge and mallet, the new bone which was three-fourths of an inch thick was cut through, when about a fourth of a pint of watery pus escaped. The whole of the shaft of the femur was found necrosed. In some parts it was not thicker than a quill, in others as thick as the thumb. It was so closely embraced by the new bone, that the greatest difficulty was experienced in extracting it. Scarcely a tablespoonful of blood was lost. The wound was filled with wet lint, to prevent its closing. He had no bad symptoms. Several pieces of bone escaped from the wound which was kept open with considerable difficulty. One month after operation, the limb was very little larger than the opposite one, and the tissues felt soft; pulse 86; appetite good. He gained flesh. There was a prominence on the lower part of the shaft of the femur, and a small opening existed opposite the outer condyle. When a probe was introduced, roughened bone could be felt. Early in April, Mr. Beane cut down on the outer side of the condyle, and removed two large thin pieces of the diseased external condyle. A sinus was then discovered passing through the new bone to the centre of the enlargement of the lower part of the femur, and loose bone could be felt with the probe. The new bone was cut through with the gouge, and a piece of necrosed bone, of the size of a large walnut, removed. The capsule of the knee-joint was not touched; the length of time the knee had remained motionless, had caused slight ankylosis of the joint, and the capsule to diminish in size. From this time he progressed most satisfactorily. For some time there was a free discharge of laudable pus, accompanied occasionally by small spiculae of bone. The latter, however, ceased to come away in September,

and the wounds rapidly closed. In October, he left for the country with a good limb; motion was being gradually restored to the knee-joint—the opening made on the outer aspect of the thigh would scarcely admit a probe, and the whole limb was not larger than its fellow. He was in sound health, and gaining flesh rapidly. (*Medical Record*.)

**NEW TENT FOR DILATING PURPOSES.** Dr. Sloan, of Ayr, has discovered a new material possessing many and great advantages over the ordinary sponge-tent. It is the dried stems of the sea tangle (*Laminaria Digitata*); this, like all the algae, being purely cellular in structure, possesses the property of drying readily at ordinary temperatures, and, in so doing, greatly diminishes in bulk, becomes firm, elastic, and tenacious; in this state it may remain for years, and by mere absorption of moisture, readily assumes its original size; it can easily be cut to any shape, and, being one of our commonest sea-weeds, exists always in abundance. It is readily recognised by its appearance of possessing root, stalk, and branches. In this climate it acquires a length of from two to twelve feet, with a diameter of from one to several inches. Dr. Sloan has not only tried this substance himself, but many of his friends have also used it, and found it very efficient for the purpose; one of them writes, “in every case in which the sponge-tent requires to be used the tangle tent can be used, and I have no doubt will, by and by, come into general use.” One great advantage ascribed to it is, that it does not occasion anything like the factor which the use of the sponge gives rise to. The author thinks it may be used for dilating the os uteri, urethra, the lacrymal canals, and Eustachian tube. If freely exposed to moisture, it doubles its diameter in four hours. (*Glasgow Med. Jour.* and *Dub. Med. Press*.)

**COOLING OF THE BODY AFTER DEATH.** The following is a summary of Dr. B. W. Richardson's views, lately given on this subject:—

1. If the body is left dead with its vessels full of blood, the temperature of the blood being unaffected by the mode of death, the cooling is slow, but in the great majority of cases is completed in fifteen hours.

2. If the body is left dead from direct and absolute loss of blood, cooling to the temperature of the surrounding medium is completed, in regard to the external surface, in two hours.

3. If the body is left dead from sudden and profuse exudation, as in cholera, the cooling to the temperature of the surrounding medium is completed in two hours.

4. If the body is left dead from obstruction to the circulation, as from fibrous concretion, the body, in so far as the external surface is concerned, will be chilled to the temperature of its surrounding medium in two hours.

5. In these last three named forms of death, if the death be slow, the heat of surface may sink to that of the surrounding medium, even before life has ceased.

6. The body, when dead, will sink steadily in temperature to the medium of its surrounding envelope: in the air to the air, in a stone tomb to the tomb; but it will not afterwards rise in temperature by the application of any external warmth, short of such as would destroy its texture.

7. After all forms of death, the age and corporeal condition of the person must be taken into account; youth and old age, great thinness of structure, deficiency of food, and states in which blood is diverted from its systemic course, quicken the decline of the animal heat.

8. In taking observations for medico-legal purposes, in any suspected case, the mere test of the hand is altogether unreliable; for as the terms heat and cold are relative only, and as between the hands of different observers the greatest natural difference may prevail—that which to one hand would signify warmth, to another

would signify cold. If any observation in respect to temperature be made, therefore, it should be carried out with the thermometer, the points at which the temperature is taken being the flexures of joints, the mouth, or the nostril. (*Medical Critic and Psychological Journal*.)

**A REAGENT FOR DETECTING BEETROOT ALCOHOL.** M. Cabasse proposes sulphuric acid as a precise reagent for beetroot alcohol. By mixing three parts, in weight, of this alcohol with one part of sulphuric acid, a red colour is immediately produced, which preserves its intensity for several months. No similar result is produced by operating with vinous alcohol. On operating with perfectly colourless alcohol, the liquid does not change directly, but after a shorter or longer time takes a slightly amber tint; this amber tint, which belongs to alcohols which have remained a certain time in cask, is heightened only by sulphuric acid, since it existed previously, but has no analogy with the red colour of beetroot alcohol. The following are the results obtained by the action of sulphuric acid on mixtures of definite proportions:—1. Vinous alcohol, three parts; beetroot alcohol, one part; red colour, apparent only with a white paper placed behind the flask. 2. Vinous alcohol, two parts; beetroot alcohol, two parts; decided red colour. 3. Vinous alcohol, one part; beetroot alcohol, three parts; red colour still more decided. It is then easy, by means of pure sulphuric acid, to recognise immediately beetroot alcohol and its mixture in various proportions with vinous alcohol. The coloration produced by using the reagent in the given proportion is due most probably to the action of the acid on the volatile oil, from which it has hitherto been found impossible to free the alcohol, to which it communicates its peculiar flavour and odour. (*Répertoire de Pharmacie*, and *Chemical News*.)

**RADICAL CURE OF A CASE OF FISTULA IN ANO, WITHOUT THE USE OF THE KNIFE.** Assistant-Surgeon D. B. Hoffman, of California, relates the case of a man aged 38, who had a fistulous opening on the right side of the rectum, about three-fourths of an inch from the edge of the true orifice, in a highly inflammatory and painful state. No organic cause of any kind could be found. He objected to operation. Mr. Hoffman, therefore, directed him to remain in his room, and keep as quiet, and rest as much in a recumbent position as possible; to use a cold water bath to the affected parts frequently, and at the same time, throw cold water up the bowels freely with a syringe. He also injected the fistular opening once a-day with the tincture of iodine, and gave once a-day a tablespoonful of the following prescription:—Flowers of sulphur, powdered resin, of each ʒss; clarified honey, ʒj. This course of treatment cured him in twenty-three days. His diet, during that time, was altogether of a bland nature; no solids of any kind were allowed, and the use of tea and coffee was prohibited. Milk and strong beef soups were the principal food used. The cure took place three years ago. (*San Francisco Medical Press*.)

**RECOVERY FROM GUNSHOT WOUND OF THE HEAD.** Charles McCarty, private, was wounded at the second battle of Malvern Hill, by a ball from a pistol in the hands of a rebel cavalryman. The wound was received while he was making a charge upon the rebel infantry, behind which the cavalry were posted. The infantry broke and fled, leaving the assailing party almost upon the sword points of the opposing force, at which time the wound was received, the distance being about three feet. So small was the intervening space, that the powder entered the skin, causing permanent discoloration. The ball entered at the inner canthus of the right eye, taking an irregular downward course, lodging under the skin of the opposite side, on a line with the posterior edge of the mastoid process of the temporal bone, and half

an inch below its inferior extremity, in which position the ball remained, until, a short time after the battle, he was placed under the care of a surgeon, who extracted the ball by a slight incision. The injury sustained by the eye was comparatively slight, causing opacity of the lower portion of the cornea and to a certain extent injuring the conjunctiva and sclerotica, causing a small track to slough out, which cicatrised, adhesion having taken place between a portion of the conjunctiva of the eye and that reflected upon the inferior lid. He was still able to distinguish large objects at a short distance. After he received the injury, he lost all consciousness as to what was being enacted around him; his only recollection being that of a severe pain in the head, which, however passed off in a few days. There was no other prominent symptom, and he suffered but little for some time. The counter-opening by which the ball was extracted healed, leaving a hard cicatrix. The treatment employed was cold water dressing to the part, with slight purgation. He was also given ten grains of Dover's powder at bed-time, from which he received great relief and a good night's rest. At the time of the report the patient was nearly ready to leave the hospital, though permanently unfitted for the duties of a soldier. (*Philadelphia Med. Journal.*)

SATURDAY, FEBRUARY 28TH, 1863.

### MEDICAL HEALTH ASSURANCE.

SEVERAL letters which we have lately received lead us to ask the question, do the members of our profession as a body need a society which would come to their aid in the hour of sickness? The correspondence to which we allude, and the social condition of the medical profession as known to all of us, can, we apprehend, leave but one answer to the question, and that is, that a society of the kind alluded to would be an immense boon to the profession, if it could be established on sound principles and honestly carried into action.

A certain percentage of our medical brethren are every year stretched on a bed of sickness. Our profession is notoriously a poor and an ill-paid profession. The great body of us are dependent on our daily labours for daily support; and they are the exceptions only who are enabled to realise world's goods enough to protect them against the accidents of fortune. In our profession, a man's income ceases to come in when he ceases to labour. The clergyman's stipend may run on, the lawyer's bills may still increase, the manufacturer's mills are not stopped, though the lawyer, and the clergyman, and the manufacturer be prostrated by sickness. But it is not so with the medical man; with a cessation of his visits ceases his income absolutely; so that, in an especial manner, is the medical man's income dependant upon his health. During sickness, whilst he and his family are still consuming, the renewal of the means of life is arrested. Consumption with-

out reparation is his position then. And how many are there of our profession who have private means sufficient to meet the emergency? The necessary consequence is that, during his illness, the medical man is forced to mortgage his future exertions in order to meet the present difficulty. And when he rises enfeebled from his bed of sickness, he starts again in the battle of life weighted and oppressed by an accumulation of bills on the creditor side of his account.

Would not a friendly society—a society which would come to the medical man's aid at the critical moment—annually relieve a large number of our profession from this painful struggle? Would it not enable many a medical man who struggles on at his labours—fighting against the onset of sickness—to subject himself to the same suitable conditions as he would prescribe for his patient at the earliest approach of disease? Has not this struggle against impending sickness cost many a life, which might have been preserved had such a society been at hand to offer its protection and assistance?

Certainly, the proposal of Dr. Bryan and Mr. Gramshaw seems to us to be most excellent and reasonable. At all events, we consider it our duty to bring the subject prominently under the consideration of the profession.

We have done more than this; we have requested a friend, an eminent actuary, to give us his opinion as to the practicability of establishing such a society; and add his suggestions and opinions for the benefit of those who are interested in the subject.

"I see," he writes, "no reason why the scheme of health insurance should not work satisfactorily, provided you get it well supported, which is *indispensable*. It should be cautiously managed at first, and economically. It would, of course, be on the mutual principle, like the friendly societies for working men; in fact, it would be a friendly society of a higher class.

"I am decidedly of opinion that it should, *in the first instance*, be limited to the medical profession, and that at the outset all the allowances should be of the same amount. To illustrate this point, one medical man in large practice might consider £20 a week a proper allowance in case of incapacity through sickness, whilst another would, perhaps, think £5 a week a handsome sum. It would be inconvenient, and indeed hazardous, at first, to allow of such inequalities.

"The main point, however, is the amount of the subscription to be paid by the members; and to determine this with approximate accuracy, data of sickness should be obtained, and premiums computed, before any other actual step is taken. It is well known, to all who have looked into the subject, that the great majority of friendly societies are in an unsatisfactory—*i. e.*, insolvent—condition, because the

contributions of the members are insufficient for the benefits promised to them. I do not know what is the average rate of sickness; but if, on the average, each member of the medical profession has one week's incapacity in the year through sickness, then the annual subscription to provide for an allowance of £5 per week during sickness would be £5 *per annum*—leaving the expenses out of the question. If there are two weeks sickness in the year on the average, the subscription would be £10 *per annum*, and so on.

"It is obvious, however, that for such a society to be on a stable basis, the actual subscriptions should be considerably more than the amounts theoretically necessary; and the surplus at the end of each year should be applied to reduce the contributions of future years.

"I believe it is established that the average sickness increases slowly with the age, so that the older members would have to pay more than the younger ones; and no persons above a certain age—say 60 or 65—should be admitted as members, or allowed to remain members after attaining that age.

"I see no good and sufficient reason for the limitation that no demands should be made during the first twelve months; in fact, this seems to diminish the usefulness of the society for no good object.

"With regard to organisation: no expense should be incurred in the outset upon buildings, deed of settlement, etc. The directors should be content with nominal fees for a time; and it would suffice, I think, to have one moderately paid officer at first."

#### PHLEGMASIA ALBA: EMBOLIA.

M. TROUSSEAU has lately made this disease the subject of a series of interesting clinical lectures, of which we here give the summary.

The cause of phlegmasia is obstruction of veins. This obstruction is caused by the spontaneous coagulation of the fibrine of the blood, and very rarely by what is called coagulating phlebitis. Spontaneous coagulation takes place more especially in cachectic states of the body and after confinement. The clots which produce the obliteration contain a large quantity of fibrine in a molecular or fibrillate condition, red and white globules, fatty matter, and hæmatine. These clots may become disaggregated, and disappear without leaving any trace of their existence in the obliterated vessel, and without producing any appreciable general disturbance of the body. Moreover, they may become organised, being converted into connective tissue. In such cases, the diameter of the vessel may be converted into a cavernous trabecular structure, and the circulation be still carried on through it in its altered state. Or, again, the vessel may be converted into fibrous or

fibro-calcareous cord. These are different modes of termination of phlegmasia. The venous clots have two extremities—one peripheral, which is multiple, and ramifies in the origins of the veins; the other extremity may be called the cardiac. The cardiac extremity often assumes a special form—a serpent's head form. It may be of a cystic nature, the walls of the cyst being composed of stratified fibrine, and the contents of it being disaggregated softened fibrine, which has the appearance of pus. The head of the clots is generally non-adherent, and is situated at the opening of an afferent vein. Being more or less firmly attached *in situ* by a pedicle or neck, this extremity—the head—may be detached and carried away by the current of the blood, and finally arrested in one of the branches of the pulmonary artery, producing the symptoms of pulmonary embolia. These symptoms, of course, vary much, according to the general condition of the patient—the extent, the volume, and the composition of the embolic clots. Life may be quickly destroyed by these cardiac and pulmonary embolia; and in such case death is the immediate result of the passage of the clot into the heart, or into the trunk or large branches of the pulmonary artery. The clot may become fixed in one or other of the divisions of the pulmonary artery, and there undergo various modifications—absorption or molecular disaggregation; or it may occasion temporary or permanent obliteration of the vessel. Permanent obliteration will give rise to a third order of accidents in the pulmonary parenchyma; viz., most frequently local anæmia, œdema, pneumonia; and more rarely gangrene of the lungs.

#### ARTIFICIAL ILLUMINATION.

DR. FRANKLAND, in a lecture lately delivered at the Royal Institution, on the above subject, stated that, during the last ten years, very little improvement had taken place in the means of producing artificial light. Lately, however, a new illuminating agent had been introduced, and the magneto-electric light had received an important application. In gas-manufacture, again, very little improvement had been made in these ten years. Sulphur was still found in it in considerable and perhaps undiminished quantity. The Rev. Dr. Bowditch has, however, shown how it may be got rid of; viz., by passing the gas over hydrate of lime heated to 400°. Recently, a new illuminating body—acetylene—has been discovered in coal-gas; and the discovery may perhaps entirely revolutionise the manufacture.

"The use of animal and vegetable oils for illuminating purposes had received no new development in the past ten years; but a new source of light of the greatest importance has been discovered in the oils obtained by the distillation of coals and shales at low temperatures. This oil, however, has recently found a formidable rival in the oil distilled by Nature herself. The native oil of the

United States and Canada is obtained in immense quantities: from the latter country alone as much as 20,000,000 of gallons have been procured, which, it has been calculated, would give as much light as 180,000,000 of pounds of sperm candles."

### THE WEEK.

WE should like to inquire of those of our medical brethren who admire the system of gratuitous medical services whether or not they consider that the medical profession in Ireland are bound to give gratuitously certificates of the cause of death of the patients whom they have attended? We see under the Act for Registration of Births and Deaths in Ireland, now on its passage through Parliament, that the medical men are required to perform this bit of service gratis to the public. Would the government ask them to do it, except for the notorious fact of the unlimited gratis work done by the profession?

A LARGE reduction is made in the medical establishment, services, and supplies of the army for the year 1863-4. The expenditure under these heads was, in 1862-3, £327,311; whilst for the forthcoming year the estimate is £255,993. There has been a general reduction in the army estimates for this year; but we believe that the screw has been applied with especial rigour in the medical department.

WE read in the journals that last week a fee for making a *post mortem* examination was refused to a house-surgeon of the London Hospital by the coroner on the following grounds, as stated by the "coroner, Mr. R. Walthew, who remarked that Mr. Humphreys had been obliged to refuse payment on the ground that *the medical officers were paid a general salary, and in their duty was included these examinations.*"

At the last annual meeting of the Cancer Hospital, we read:

"The surgeons' report stated that the completion of the eleventh year of the existence of the hospital strengthened the opinion previously expressed—that cancers may be cured. The large number of cases which had come under the care of the surgeons had enabled them to arrive at data which, without the existence of the special hospital, could not have been obtained. Many surgeons and physicians, who had signed a protest against the hospital on the ground of its special character, had since acknowledged its usefulness by sending patients from their own hospitals to receive its benefits." We think the profession will agree with us that the light of this hospital should not be hid under a bushel. The surgeons, for example, who make these statements, are bound to tell the profession why their opinion as to the curability of cancer is strengthened year by year. All the medical world should have the benefit of this consoling hope. What are

the data furnished to the surgeons of the hospital upon which they found this hope of cancer-curability? What, again, are the special facts here obtained which could not have been obtained at a general hospital? We are sure the surgeons' report was not mere vain assertion; and we, therefore, call upon those gentlemen, in the name of cancer-suffering humanity, to give the profession the benefits of their special experience at this special hospital.

TYPHUS appears to be raging in a part of the Vienna Hospital at the present moment. Six assistant-physicians are at the present moment suffering severely from the disease.

The Emperor and Empress of Austria lately paid a long visit to the Irrenanstalt, and expressed their high satisfaction at its excellent condition. On the following day, Dr. Riedel, the Director, received the Cross of the Order of Francis Joseph.

The faculty of Prague have just set an example which might well be followed by the Medical and Chirurgical and other Societies. It has issued a circular requesting all the medical men belonging to it to send in their *cartes de visite* before the end of April.

When shall we find, asks *L'Union Médicale*, the medical man rich enough in heart, in devotion, or in purse, ready to illustrate and immortalise himself by a foundation similar to that which has been established in England by Mr. Propert, and which Orfila was anxious to have in France?

The celebrated Professor of Clinical Medicine at the Faculty of Medicine in Madrid, M. Drumen, has died suddenly. He was President of the Royal Academy of Medicine and physician to Queen Isabella. He was remarkable for his high sense of professional dignity and honour as well as for his learning. On the occasion of the introduction of homœopaths at the court, he protested, and gave in his resignation, which was not, however, accepted. It is by such acts, says his chronicler, that medical men honour themselves and preserve the esteem of their clients.

M. Florence Prévost, a distinguished naturalist, has from time to time during the last thirty-five years, made a collection of the stomachs of different birds taken at different times of the year. The stomachs, with their contents, are dried and fixed on cards. His observations prove that birds in general are much more useful than hurtful to our crops; and, as regards the granivorous species, that the injury which they do at certain seasons is largely compensated by the destruction of insects which they effect at other seasons.

M. Riberi, by will, left a fund for the payment of a prize of 20,000 *francs* triennially for the next twenty-one years (seven prizes in all). The first of these prizes will be decided after December 31st, 1864. All works, whether in manuscript or published, written during the three years (from Jan. 1st, 1862, to Dec. 31st, 1864), on medical or surgical subjects, may be forwarded for competition. The Turin Academy of Medicine, who adjudicates, will give the preference to those works which indicate a distinct progress in the science of medicine. Of printed works, two copies must be forwarded. Printed works or manuscripts may be translated into Italian, Latin, or French. All works must be sent in before Dec. 31st, 1864, and will become the property of the Academy.

### THE LATE DR. EDMUND LYON OF MANCHESTER.

EDMUND LYON was born in 1790, being the third son of the Rev. James Lyon, then patron as well as rector of the very valuable living of Prestwich, in Lancashire. He became the pupil of Mr. Benjamin Hutchinson, an eminent surgeon at Southwell, and author of the *Biographia Medica*, whose affectionate esteem and praise he won by his steady industry and exemplary conduct. He went thence to London, where he became a Member of the College of Surgeons; and afterwards he graduated in Edinburgh. He settled in Manchester; and on the retirement of Dr. William Henry in 1817 from the physiciancy to the Royal Infirmary, Dr. Lyon was elected in his stead. Notwithstanding the standing given to him by this appointment, and a most exemplary performance of its duties, his progress in general practice was exceedingly slow. Year after year of hard work brought hardly any accession of income. He was another example of the ever true remarks of Dr. Johnson, that "a physician in a great city seems to be the mere plaything of fortune; his degree of reputation is for the most part totally casual: they who employ him know not his excellence; they that reject him know not his deficiency." It was not till about five-and-thirty years after he began the study of medicine that he obtained an income which, if it had been spread over many years, would have been a moderate remuneration for his toil and devotion. In 1841, after twenty-four years service, he resigned the physiciancy to the Infirmary, when the Board entered on the books their testimony to his "unremitting, exemplary, and zealous exertions," and elected him consulting-physician to the charities. In the year 1851, being in feeble health and possessing a competency, he retired from practice, and devoted himself to the business of three important public institutions—the Royal Infirmary, the Royal Institution, and Henshaw's Blind Asylum. Of the Royal Institution he was at his death the President. The committees of these three institutions have expressed in glowing terms their sense of the loss they have sustained in his death; that of the Infirmary speaking of his unremitting and exemplary services for nearly forty-six years; that of the Royal Institution, of his devotion of the energies of an accomplished mind to its management, and of his kind-heartedness and goodness; while the third speaks of the most extraordinary and exemplary manner in which he devoted his attention to his duties as a member of the Board of Henshaw's Blind Asylum.

He published very little. His most important papers are, *A Sketch of the Medical Topography and Statistics of Manchester*; and *Observations on Ileus*.

The medical profession has reason to be proud of one of its members who won so high a character by years of devotion to public service.

[The above is a summary of a memoir of the life of Dr. E. Lyon, just published by Dr. Crompton of Manchester.]

## Association Intelligence.

### NOTICE REGARDING NEW MEMBERS.

By desire of the Committee of Council, the General Secretary requests that the Local Secretaries will be good enough to forward to him the names of all New Members who join the Association through the Branches; as otherwise the JOURNAL cannot be sent to them.

PHILIP H. WILLIAMS, M.D., *General Secretary*.

Worcester, November 10th, 1862.

### BRANCH MEETINGS TO BE HELD.

NAME OF BRANCH.	PLACE OF MEETING.	DATE.
LANCASH. & CHESHIRE. [Ordinary.]	Royal Institution, Manchester.	Thursday, March 12th, 3 P.M.

### EAST KENT DISTRICT MEDICAL MEETINGS.

THE next meeting will be held at the Pavilion Hotel, Folkestone, on Thursday, March 5th, at 3 P.M.

THOMAS BOYCOTT, M.D., *Hon. Sec.*

Canterbury, February 10th, 1863.

### LANCASHIRE AND CHESHIRE BRANCH.

An ordinary meeting of this Branch will be held at the Royal Institution, Manchester, on Thursday, March 12, at 3 P.M. Notice of papers, etc., to be sent to the Honorary Secretary.

Dinner will be provided at the Clarence Hotel, Spring Gardens, at 5 o'clock.

A. T. H. WATERS, M.D., *Honorary Secretary*.

Liverpool, February 16th, 1863.

### BIRMINGHAM AND MIDLAND COUNTIES BRANCH: GENERAL MEETING.

A GENERAL meeting of this Branch was held on February 12th; HENRY DUNCALFE, Esq., of West Bromwich, in the Chair. There were also present fourteen members and a visitor.

*New Member.* Dr. James Williams of Malvern was unanimously elected a member of the Branch.

*Alteration of Law.* Mr. BAKER and Mr. DOWNES gave notice that, at the next general meeting of the Branch, they will move the following alteration in Law 4:—

"That instead of the words 'That a general meeting of the Branch be held thrice annually', the words 'That a general meeting of the Branch be held on the second Thursdays in October, November, December, January, February, and March,' be substituted."

*Papers.* The following papers were read.

1. On the Diagnosis of Retro-uterine Hematocele. By W. F. Wade, M.D.
2. On Two Cases of Cyanosis. By B. W. Foster, L.K. & Q.C.P. The patients attended.

# Special Correspondence.

## LIVERPOOL.

[FROM OUR OWN CORRESPONDENT.]

At the *Royal Infirmary*, on Tuesday, February 3rd, Mr. Bickersteth operated upon a case of more than ordinary interest. A porter, aged about 40, was admitted in consequence of a tumour of considerable size which occupied the whole of the right side of the neck, and had been increasing gradually to its present dimensions for about two or three years. It was not painful, and had produced little or no inconvenience to the patient, until quite recently, when some difficulty in swallowing, buzzing noises in the ears, dizziness, and other indications of pressure upon the nerves and vessels, had begun to be felt. The tumour was round, firm, hard, and well defined, and presented all the characters of a solid growth; it was evidently deeply seated beneath the cervical fascia and the sterno-mastoid muscle; and from its size, situation, and connexions, so far as they could be judged of by palpation, it afforded the prospect that its extirpation would prove a tedious and formidable surgical undertaking. After careful and repeated examinations by Mr. Bickersteth and his colleagues, Mr. Stubbs and Mr. Long, it was concluded that it was a firm solid growth; and its removal resolved upon. A free crucial incision was made through the integuments, and the dissection of the exposed tumour was commenced, but had not been carried far before the sac was punctured; and a copious escape of purulent matter followed, showing at once that an error in diagnosis had been made, and that a large and very thick cyst, containing matter tightly bound down by the muscle and fascia, had been mistaken for a solid tumour. It was found that the cyst or abscess had dissected out the nerves and vessels of the region in which it was situated, leaving the sheath of the carotid artery exposed to the extent of nearly three inches. A portion of the anterior wall of the cyst, of about the size of a penny-piece, was removed; and, some lint being placed in the wound, the patient was sent to bed.

Mr. Bickersteth remarked that, notwithstanding the error in diagnosis, the operation so far had accomplished all that could be desired, by at once revealing the actual nature of the disease, giving exit to an accumulation of matter, and relieving the patient from symptoms that threatened to become formidable. As to the result, he thought there was a fair chance of the man's recovery; but of course, when the main artery was exposed to so great an extent, there was some risk from the possibility of ulceration taking place in the coats of the vessel. He had seen a very similar case in the practice of Mr. Syme, in which the same difficulties in diagnosis had existed, and in which the tumour had been entirely removed by a close and prolonged dissection from the vessels. Its exact nature was not discovered until an incision into the sac showed that it consisted, as in the present instance, of a thick membranous cyst filled with dirty brown pus. The case has since

progressed favourably, the wound is granulating, and the patient out of all danger.

By a curious coincidence, I have to report another operation, at the *Northern Hospital*, by Mr. Hakes, in which also the result proved that an error in diagnosis had occurred. The case was one of what is conventionally called ovariectomy, but which may be more strictly defined as abdominal section for the removal of a tumour. The patient was a pallid, rather delicate-looking woman, 42 years of age, the mother of two children, the youngest aged 15. She first noticed the swelling about eighteen months ago, and came under Mr. Hakes's notice in February of last year. At that time the abdomen appeared to be full of ascitic effusion, with a moveable tumour at the lower part. She was tapped in the usual place, and several pints of amber-coloured fluid were drawn off; after which an irregular, nodulated, moveable tumour was plainly felt. The uterus was moveable, but less so than usual; and attached to the cervix was a small polypus. The case was now regarded as one of uterine tumour with ascites. About nine months afterwards—at the end of November—she was again tapped; and, after about a pint of fluid had been drawn off, the flow stopped, and the trocar came into contact with the tumour. Ten days afterwards, she was again tapped—this time above the umbilicus; and a large quantity of fluid was withdrawn. A large tumour, however, still remained, evidently consisting of some large cysts, as well as some solid matter. At a careful examination two or three weeks later, in which Dr. Grimsdale took part, it was concluded that it was an ovarian tumour, and a case in which the operation for its removal might be proposed; and the woman was admitted into the Northern Hospital.

The operation, performed on the 29th of last month, was commenced by an incision of the usual length, which was afterwards extended to about an inch above the umbilicus. The tumour was found to be covered by the attenuated and reticulated omentum, to which it was adherent at numerous points. There were also adhesions to the smaller intestines at two spots. Scarcely any pedicle could be said to exist; and the small band of tissue representing it, and by which the tumour was connected with the uterus, was tied with silver wires, first in two halves, and then by one wire encircling the whole; the wires were cut off short, and left in the cavity of the abdomen. When first exposed, the tumour presented almost the appearance of a collection of intestines matted together, and was found to consist of a mass of cysts of various sizes, with thin walls, and for the most part limpid contents; one or two of the cysts, however, contained half-solid bloody matter. The tumour was removed, of course, without using the trocar. One or more cysts were unavoidably ruptured, and there was a considerable escape of fluid into the abdominal cavity. The right ovary was seen to be enlarged; the left was not sought for, as it was supposed to have been involved in the diseased mass. A tumour, of about the size of a large walnut, was noticed on the body of the uterus. The cavity of the abdomen was carefully sponged out, and the wound closed in the usual way. The patient for several hours appeared to be doing

well; but she never completely rallied, and died thirty-three hours after the operation, apparently from simple shock. The *post mortem* examination showed that no inflammatory action whatever had occurred. The wound was firmly united. Both ovaries were found in their usual situation, each containing two or three small tumours; and in addition to the polypus on the cervix, and the tumour projecting from the peritoneal surface of the uterus, seen during the operation, one or two small fibrous tumours were imbedded in its walls.

It is not a little remarkable that this is the second case which has occurred in Liverpool within a year, in which a fibro-cystic uterine tumour (a disease so rare as to be almost denied an existence by some pathologists) has been removed in an operation commenced with the expectation of finding an ovarian cyst. The other case, your readers may remember, occurred in the practice of Mr. Fletcher in the workhouse hospital, and terminated in the complete recovery of the patient. It is fully detailed in the JOURNAL of November 8th, 1862, p. 499.

Within the last few days, an unusual form of fatal injury, which will, of course, become the subject of investigation in the coroner's court, has occurred here; and through the courtesy of Mr. Bickerton, the surgeon who has charge of the case, I am enabled to give the following interesting account of the matter.

A young man, while playfully wrestling with a companion, was thrown on his back, the other man falling with his knees upon his abdomen. The injured man got up, and immediately turned deadly pale, but complained of no pain, and was not aware that he had sustained any serious injury. He was, however, taken home in a cab, and soon became collapsed, and so remained from Saturday night until the following Wednesday, when he died. As he was unable to pass urine, a catheter was passed, and fully four quarts of bloody fluid were drawn off. He had stercoraceous vomiting a short time before his death. A *post mortem* examination at once revealed the cause of death. The fundus of the bladder was rent across from side to side, the wound being fully four finger-breadths in extent. There was scarcely any fluid either in the pelvis or in the abdomen, and the amount of peritonitis was much less than might have been expected under the circumstances. No injury to any other viscus could be discovered. It seemed probable that, at the time of the accident, the bladder was fully distended; and that the rent, from its situation, was caused by hydraulic pressure exerted by the contained fluid under the compression of the man's knees. The fluid drawn off by the catheter was evidently from the cavity of the pelvis.

**CHEAP FOOD FOR THE WORKING CLASSES.** Great public interest is being excited by the account of the working of the plan first brought out by Mr. Corbet, of Glasgow, for supplying wholesome and well-cooked food to the working classes at a really cheap and yet remunerative price. By this plan a good breakfast may be had for 3d., a capital dinner for 4d., and rations during any hour of the day for 1d. Thus a man may live like a prince on a shilling a day. The extension of the system to London and other large towns is now under consideration.

SAMUEL CARTWRIGHT, JUN., ESQ., President, in the Chair.

#### DIAGNOSIS OF DENTAL NEURALGIA.

BY W. A. N. CATTLIN, ESQ.

THE author of the paper commenced by a comparison of morbid conditions of the teeth, which have in his experience given rise to neuralgia with analogous pathological conditions in other organs, as well as with conditions not strictly analogous, but in which local disease had been shown to have had an etiological relation with neuralgia. He discussed briefly, the probable causes of the variety which every one knows to occur in the degree of pain suffered by different individuals under circumstances of local disease apparently very similar, referring it to variety in temperament, size of nerves, etc., and then passed on to the main topic, namely, an inquiry as to how far neuralgia due to a morbid condition of the teeth may be distinguished in practice from that dependant upon constitutional causes, or local mischief elsewhere. The conclusion arrived at is, that as in all other questions of difficult diagnosis, the surgeon must carefully examine not only the local condition of those organs and parts of the body most likely to originate the neuralgia, but into the general constitutional condition of his patient, and weighing carefully the facts he ascertains, exercise his judgment in determining the proper conclusions to be arrived at.

Before condemning a tooth as the cause of a local neuralgia, it is thus often proper to strive after the removal of other causes of reflex irritation, and the improvement of the general health. At the same time, the writer strongly deprecates the prevalent practice of retaining diseased teeth in the mouth to the sacrifice of health and comfort, after they have become useless for mastication or appearance. The paper is illustrated by a large number of interesting cases which have occurred in the practice of the author, some of them being cited to show that the symptoms of intermittent or regular paroxysms mainly relied upon by some authors in their diagnosis of constitutional neuralgia, frequently attend local neuralgia in patients of shattered health. He recommends stimulants in full doses as an antidote to nervous shock, and as the best remedy for the neuralgia which sometimes succeeds dental operations.

An interesting case is recorded, in which deafness was cured one hour after the extraction of a tooth.

### HARVEIAN SOCIETY OF LONDON.

FEBRUARY 19, 1863.

HENRY W. FULLER, M.D., President, in the Chair.

#### ON THE USES AND VALUE OF GALVANISM AND ELECTRICITY IN GENERAL PRACTICE. BY HARRY LOBB, ESQ.

He commenced by stating that it must not be supposed that galvanism was only useful in the hands of the specialist, but that there was a wide sphere open to its use in general practice; and, after a few remarks upon the resemblance of the nerve-force and the galvanic current, he proceeded to describe the apparatus he recommended for general purposes. These were magneto-electrical apparatus, worked by a powerful spring, whereby an energetic shock-current could be obtained without turning a handle; and was, in fact, self-acting, and would continue for twenty minutes without being rewound. This apparatus was made for the author by Messrs. Shaw and Son. The other was the Pulver-

macher galvanic battery, for the generation of the continuous current. These were all that were wanted by the general practitioner to produce the ordinary results in electro-therapeutics, and could be highly recommended, on account of their convenience, portability, cleanliness, and non-liability to get out of order.

Mr. LOBB then demonstrated the action of each apparatus, describing the necessary conductors and their application; and showed how the electric bath was administered. He then explained how valuable electricity was in diagnosing the seat of obscure diseases, stating that frequently the organ in fault was found to be quite remote from the one suspected.

The author then explained the great value of galvanism in all cases of chronic rheumatism, stating that he had frequently cured cases of rheumatic paralysis of long standing in one or two sittings. The method of application of the batteries was demonstrated. The treatment by galvanism of the following affections was then explained in order; namely, neuralgia and allied disorders; constipation; chlorosis; amenorrhœa; dysmenorrhœa; as well as its value in midwifery practice, in chest-affections, asthma, aphonia, indigestion, paralysis (functional, reflex, and organic), anæsthesia; in chorea and delirium tremens; in muscular debility, spinal curvature, knock-knees, bow-legs, inveterate ulcers, boils and carbuncles, and in malignant disease. He concluded with its great utility in drowning, chloroform accidents, poisoning, suffocation, etc.

The author hoped that the time was not far off when every educated practitioner would be as familiar with the application of galvanism to the treatment of disease as he now was with the administration of drugs. Each aided the other, and their judicious combination was now producing results hitherto undreamt of. Many cases, formerly abandoned as incurable, were now amenable to treatment; and advancing science constantly added to their number.

The author concluded by earnestly requesting the members to experiment upon the value of galvanism, promising them ample reward for their labour.

**THE DISEASE AMONGST SHEEP IN WILTSHIRE.** The committee appointed to inspect flocks, during the late outbreak of ovine disease in Wiltshire, has been dissolved. At an aggregate meeting of the Society for Prevention of the Disease of Sheep, held at Devizes, the members of the committee reported that the disease was so far removed, that they had no further duties to perform. A vote of thanks was passed to the committee for its services.

**INFANT MORTALITY.** There has been lately issued a return of the verdicts of coroners' inquests in England and Wales on children under two years of age during the year 1861 and the first six months of 1862. The following are the numbers in the respective counties: England: Metropolis district, 1,545. Bedford, 27; Berks, 63; Bucks, 37; Cambridge, 93; Cheshire, 134; Cornwall, 121; Cumberland, 26; Derby, 114; Devon, 83; Dorset, 23; Durham, 50; Essex, 60; Gloucestershire, 147; Herefordshire, 21; Herts, 16; Huntingdon, 10; Kent, 56; Lancashire, 758; Leicester, 76; Lincoln, 133; Monmouth, 39; Norfolk, 64; Northampton, 49; Northumberland, 37; Notts, 70; Oxford, 58; Rutland, 5; Salop, 39; Somerset, 143; Southampton, 85; Stafford, 222; Suffolk, 52; Surrey, 20; Sussex, 62; Warwick, 50; Westmoreland, 10; Wilts, 77; Worcester, 52; York, 287; total, England, 4,978. Wales: Anglesey, 6; Brecon, 6; Cardigan, 1; Carmarthen, 10; Carnarvon, 10; Denbigh, 17; Flint, 9; Glamorganshire, 55; Montgomery, 18; Pembroke, 1; Radnor, 2; total, Wales 135. Total, England and Wales, 5,113. Out of this total there are only 690 returned as above the age of one year.

## Correspondence.

### GRATUITOUS MEDICAL SERVICES.

LETTER FROM ALBERT NAPPER, ESQ.

SIR,—Your views on the subject of gratuitous medical services, so strongly expressed in the JOURNAL of the 7th inst. in reference to its bearing on cottage hospitals, will require the most careful consideration from those engaged in their establishment. You ask on what grounds we tender our services gratuitously. My reply is, not that I am "only doing like all the rest of the professional world", but that it is the only means by which success is attainable; and, as their utility is so universally admitted, I think we are justified by attaining it even at a still greater sacrifice (if such it can be considered). If, then, it be admitted that these hospitals are desirable, and that there would not be the slightest chance of founding them if the surgeons determined to demand payment for their services, I think, in our case, the act of doing so would constitute the "suicidal folly". The inference, that it will be adding to the labour of the "hard and overworked surgeon", is not in accordance with my experience, which has proved it to be a means of greatly economising both labour and expense. It is true, lawyers do little if any work gratuitously; nor do the clergy do "gratuitous public work in our hospitals"; but do they not in schoolrooms, cottages, and in barns, give gratuitous extra services? Do not the instrument-makers (to whom I must express my obligations) liberally supply their goods to those institutions at little above cost price? Do not drapers supply clothing clubs on the same liberal terms? Do not Poor-law guardians, overseers, waywardens, and the like, give their public services without compensation? and is there not something due from us in return for our immunity from serving these offices? Admitting, then, that we foolishly do far too much gratuitously for the public, I would make this the rule of practice: Give your services to charitable institutions gratuitously, but require payment for all that entails a pecuniary cost.

You will, I trust, excuse me for expressing my opinion that your ardour in a good cause has carried you a little too far in condemning thus wholesale the liberal tendencies of our profession.

In reference to your appeal to the "medical supporters of these cottage hospitals to pause before they assist in the extension of this absurd system of professional spoliation," I must beg of my provincial friends not to be deterred by any such sophistry from carrying out a scheme which in a short time will do more to elevate the position of the provincial general practitioner, both socially and professionally, than anything that has been done since the passing of the Apothecaries' Act in 1815. It is an indisputable fact, that we have amongst us numerous members who only want the opportunity these little hospitals will afford of proving themselves in all respects masters of their profession; and, with the improved system of education, the number is daily increasing. I hope to see the day when it will be an exception for a town to be without its hospital; for it is manifestly to the interest of the poor to have them brought home to their doors; and when there is a medical staff, there can be no insuperable difficulty in effecting it.

I am, etc., ALFRED NAPPER.

February 1863.

[Our correspondent appears to place surgical instrument makers who supply instruments, and drapers who supply clothing, at only "a little above cost price", to clubs and village hospitals, on the same level (as regards the charitable nature of the gift rendered to

society) with medical men who place their gratuitous services, at all hours of the night or day, at the service of the community! Mr. Napper's *rule of practice* indicates that he considers medical services rendered to charitable institutions as of no *pecuniary* value. We again ask: What are the grounds upon which medical men should do this work of the community gratis? EDITOR.]

### MR. FOSTER AND THE LICENSE OF THE COLLEGE OF PHYSICIANS.

SIR,—It seems to me that Mr. Foster, in replying to the temperate remarks of your correspondent A, has, whilst denouncing the comments of the latter as "absurd", been singularly forgetful of the homely proverb, "Those who live in glass houses should never throw stones". I will not say that Mr. Foster does not draw his conclusions upon the strictly Baconian system, but I must confess that his method of reasoning appears to my mind to be rather of the Hibernian than of the Saxon type. In his letter, he confounds two very distinct questions; and, by presuming a reply to the first, fancies that he has answered the second. The two questions are these:—

1. Has a Licentiate of the College of Physicians any claim to the title of Doctor?

2. If he be called Doctor, has he, as a consequence, the right to affix to his signature the letters M.D.?

I conceive, sir, that it requires very slight powers of observation to perceive that an affirmative answer to the first question by *no means* involves a similar reply to the second.

I waive entirely the *exact* consideration of the first query, merely remarking that I can see no reason why the title of Dr. should not be afforded to apothecaries as well as to physicians, for the former proceed to their license in much the same manner as the latter; and that it is a strange circumstance that, although the number of those on the General Medical Council who possess degrees is exceeded by that of those who do not, the non-graduate (and, therefore, in this matter impartial) body has not recognised the quasi-claims of the Colleges of Physicians.

Language, as Mr. Foster is perhaps aware, is but a collection of sounds which represent ideas; each sound is associated with a certain notion; and hence, where there is confusion of these recognised symbols, there is confusion of ideas; just as, when money does not stand for true capital, there is, as it were, a political-economy Babel. If Mr. Foster will consult any recognised authority upon the applications of English words, he shall find that the word *degree*, besides its signification as the unit of a scale, was, on the institution of universities some centuries since, distinctly employed to designate the steps by which a student rose from an inferior to a fixed superior position. The process of advancement was termed *graduation*, and the resultant a *degree*. This degree was represented by the initial letters of its Latin name; and now-a-days, instead of saying that so-and-so is a Doctor of Medicine, we not infrequently remark that he possesses the degree of M.D. In the public mind, these letters are associated with a constant idea—to wit, that the individual possessing them has been educated in some university; and, with deplorably bad taste, it prefers a man who has come from an university, and is therefore well educated, to one who by a simpler and more utilitarian mode has become a physician.

By usage, then, the letters M.D. imply that the person to whose name they are affixed has come from an university; has passed *several severe* examinations, professional and non-professional; and has studied under distinguished men of science. How, then, knowing this, can any Licentiate of the College of Physicians be so

unscrupulous as to assume a position to which he has no claim? Why will he leave society under the impression that he has graduated, when he certainly has not done so in the accepted sense?

If it be allowable to attach to one's name the initial letters of one's calling (no matter what), how shall we discriminate between butchers' assistants and Bachelors of Arts, between Doctors of Divinity and donkey-dealers? I imagine that nothing shows more clearly the inferiority of the license of the College of Physicians to the *degree* of the University, than the struggle of those who have the former to be allowed to assume the *peculiar* title of the latter. I am, etc., ARISTOTLE.

February 1863.

[Our correspondent will, on consideration, find that he has not stated his case aright. An university education is not necessary now-a-days for the obtaining of a university degree. How many hundred Englishmen were a few weeks ago made Doctors off-hand at St. Andrew's? Moreover, the prefix of the title Dr. is no indication now-a-days, either with the profession or with the public, that the assumer of it possesses the degree of M.D. EDITOR.]

### THE MEDICAL ACT.

SIR,—You, as the editor of our JOURNAL, upon the success of the last Medical Act, so thoroughly gave the Association the credit of it, that now, since it has been in operation long enough to test it by its fruits, you must by this time have lost some faith in it as a means of preventing unregistered men from practising medicine and surgery. My own humble opinion is, now that the Apothecaries' Company have abandoned the field, and do not enforce their fine in courts of law, there is no legal standing for one registered proceeding against another who chooses to gain a livelihood as one of our profession without any kind of license. The forty-shillings fine looked so well on paper, that I candidly confess I was weak-minded enough to believe it was an honest abstraction from our hard-earned labours, and that we might in future be protected from unregistered and illegal practitioners by the Council who so adroitly had their coffers replenished and their banker's account bear such a respectable appearance. Such, we know too well, is not the case. The Act is a dead letter as regards the protecting power for registered men. May I not ask: Is not the time arriving for petitioning for its alteration; at any rate, that we may not be placed in a worse position than before the Act was passed, if we cannot persuade the legislature to alter it for the better? Facts abundant, I have no doubt, could be brought forward to prove its present uselessness; and the open defiance of those who are practising on the credulity of the public too surely proves the regular practitioner has no chance against his opponent in a court of law.

I am, etc., AN OLD ASSOCIATE.

February 19th, 1863.

### MEDICAL HEALTH ASSURANCE SOCIETY.

LETTER FROM HENRY GRAMSHAW, ESQ.

SIR,—It gives me much pleasure to find that a subject is broached in your columns this week of the greatest possible importance to by far the majority of the rank and file of the medical profession. I certainly am astonished that the question of health assurance has lain dormant so long, and indulge the hope that Dr. Bryan's letter is the first stroke of the pick, to be followed by simultaneous and united effort on the part of the British Medical Association towards establishing a good Mutual Health Assurance Society.

A few days ago, I had a conversation with Mr. Cubitt

of Norwich on this subject; and he tells me he has been deeply interested in the question for some time past, and possesses much valuable information concerning it. From him I am led to understand that any health assurance society ought to be general; i. e., not entirely confined to the medical profession, but embracing certain other classes also. He likewise states that certain kinds of disease must be excluded (as blindness and insanity), to insure the safe working of a health assurance office; and that no demands must be made for the first twelve months. If, as Dr. Bryan suggests, we had "our worthy founder as treasurer and the present honorary secretaries as a staff, the thing might be done"; but I would venture to suggest that at the very outset we require the opinion of a good actuary; and if the scheme were set afloat, we should require a working board and a good business-like secretary.

I was unfortunate enough, about three weeks ago, to fall from my horse, and was for a short time unable to discharge the duties of my profession. It was some satisfaction to my mind to know I derived a certain amount weekly from the Railway Accident Insurance Company (who met the claim I made upon them with the greatest liberality and fairness); but I could not help reflecting that, whilst I did well to insure against accidents, and well to insure in a life office, I should do still better if I insured against sickness which might come suddenly, and, swamping myself and my income, render me dependent on a world whose wisdom is embodied in the adage, "He that goes a borrowing goes a sorrowing".

I am, etc., HENRY GRAMSHAW.

P.S. I shall be most happy to cooperate with Dr. Bryan in any way, and hope the subject will be mooted at all our Branch meetings this year.

Framlingham, February 1863.

**BIRTHS, DEATHS, AND MARRIAGES IN SCOTLAND.** The eighth annual report of the Registrar-General of births, deaths, and marriages in Scotland, just issued, states that the estimated population in 126 town districts for 1862 was 1,619,952, the number of births 60,808 the illegitimate births 5,793, the deaths 41,626, and the marriages 12,557. In 881 county districts the estimated population was 1,459,697, the births 46,330, the illegitimate births 4,441, the deaths 25,533, and the marriages 7,987—thus showing the total estimated population of Scotland to be 3,079,650, the births 107,138, the illegitimate births 10,234, the deaths 67,159, and the marriages 20,544.

**ACCLIMATISATION.** This month's *Bulletin de la Société d'Acclimatation* is not devoid of interest. During 1862 the Nilgau antelopes foaled twice; the lamias, Guanacos yaks, and Angora goats were equally fruitful. The sale of eggs yielded 11,036*l*. The mortality among the live stock in the garden amounted to one-eighth in the mammalia, one-fifth in the birds of the aviary, the same in the category of palmipedes (ducks, swans, etc.), and one-fourth among the poultry. The society has received a letter from Baron Anca, President of the Acclimatization Society of Sicily, wherein he states that some cochineal sent to him by M. Hardy, Director of the Botanical Garden of Algiers, has begun to thrive and multiply on a plant of *Opuntia coccinellifera*, so that the introduction of the insect into Sicily may be considered a certainty. The Marquis de Fournès has been equally successful, at Marseilles, in his experiments on cotton-growing, and has been enabled to send the society three samples of cotton, viz: 1, Louisiana, or short staple; 2, Sea-island cotton, or long staple; 3, the *Kian-nam* quality. M. de Fournès is of opinion that the crop of 1862 is quite equal in quality to that he exhibited in London last summer, and which was considered the third, as to quality, of all the samples from other parts. (*Galignani*.)

## Medical News.

**APOTHECARIES' HALL.** On February 12th, the following Licentiates were admitted:—

Beadles, Arthur, Broadway, Worcestershire  
Bothwell, George Granville, Rathmuller, co. Donegal  
Coombe, L. M., Lying-in Hospital, Dublin  
Lyon, Isidore Bernadotte, 20, Euston Square  
Osmoud, Thomas, Thorpe-le-Soken, Essex  
Ryder, Francis James, Royal Kent Dispensary, Greenwich  
Williams, Thomas Edward, St. Bartholomew's Hospital

At the same Court, the following passed the first examination:—

Low, Alexander James, St. Bartholomew's Hospital

Admitted on February 19th:—

Blason, George John, Billingham  
Mulock, John Berry, London  
Robinson, John, Winterton, Lincolnshire  
Wigsworth, Arthur, Liverpool  
Wright, Frederick, Stamford Bridge, Yorkshire

At the same Court, the following passed the first examination:—

Ashwell, Edward, Burnham  
Puzey, Chauncey, Guy's Hospital

### APPOINTMENTS.

BRADSHAW, John T., Esq., appointed Consulting-Surgeon to the Huddersfield Infirmary.

COWELL, George, Esq., appointed Surgeon to the St. George's and St. James's Dispensary.

DU PASQUIER, Claudius, Esq., appointed Surgeon-Apothecary to the Prince of Wales.

HUNT, William J., L.R.C.P.Ed., appointed Medical Superintendent of the Hoxton House Lunatic Asylum.

KIRKWOOD, William, M.D., appointed a Member of the Executive Council of the Bahama Islands.

SAUNDERS, Edwin, Esq., appointed Surgeon-Dentist to the Prince of Wales.

### POOR-LAW MEDICAL SERVICE.

CHAMPNEYS, Henry M., Esq., to be Medical Officer for Districts 1 and 2 and the Workhouse of the Battle Union.

CRICKWAY, Edward, Esq., to be Medical Officer to the Weobly Union Workhouse, Herefordshire.

GRAYDON, S. J., M.D., to be Medical Officer for the Scotstown District of the Monaghan Union.

LODGE, Samuel, L.R.C.P.Ed., to be Medical Officer for the Bowling District of the Bradford Union.

MELLER, Charles M., M.D., to be Medical Officer for the Walham Green District of the Fulham Union.

RUSSELL, Edward, Esq., to be Medical Officer for the Sixth District of the parish of Liverpool.

### ARMY.

BARKER, Staff-Surgeon F. O., M.D., to be Surgeon 90th Foot, *vice* W. Lapsley.

CHESTER, Staff-Assistant-Surgeon A., to be Assistant-Surgeon Royal Artillery, *vice* J. F. Longhead.

CRISP, Surgeon H., M.B., 63rd Foot, to be Staff-Surgeon.

CROW, Staff-Assistant-Surgeon J., to be Staff-Surgeon, *vice* A. Morpew.

DAVIDSON, Staff-Assistant-Surgeon P., M.D., to be Assistant-Surgeon 5th Foot, *vice* C. H. Leet.

HANBURY, Staff-Assistant-Surgeon J. A., M.B., to be Surgeon 63rd Foot, *vice* H. Crisp, M.B.

JONES, Staff-Surgeon H. H., M.D., to be Surgeon 86th Foot, *vice* J. Sawyers, M.D.

LAPSELEY, Surgeon W., 90th Foot, to be Staff-Surgeon, *vice* F. O. Barker, M.D.

OAKES, Staff-Assistant-Surgeon F., to be Staff-Surg., *vice* W. Skeen.

WELD, Staff-Surgeon W. W., to be Surgeon-Major, having completed twenty years full-pay service.

To be Staff-Assistant-Surgeons:—

LEFT, Assistant-Surgeon C. H., 5th Foot.

LONGHURST, A. E. T., M.D., 13th Foot.

### INDIAN ARMY.

DAVIDSON, Deputy Inspector-General H. G., to have the honorary rank of Inspector-General of Hospitals.

### MILITIA.

CRIPPS, E., Esq., to be Assistant-Surgeon Royal North Gloucestershire Regiment of Militia.

**VOLUNTEERS.** (A.V.=Artillery Volunteers; R.V.=Rifle Volunteers):—

KELLY, F., Esq., to be Surgeon 2nd City of London R.V.

MORRIS, G. S., Esq., to be Assistant-Surgeon, 20th North Riding R.V.

SANS, J. S., Esq., to be Assistant-Surgeon 3rd Kent R.V.

## To be Honorary Assistant-Surgeons:—

BOSTOCK, J. S., Esq., 7th Surrey R.V.  
 PAYNE, E., M.D., 2nd Surrey A.V.

## BIRTH.

\*BROWN. On February 22nd, at Rochester, the wife of John Dan Brown, M.D., of a son.

## DEATHS.

BEDDOES. On February 19th, at Shrewsbury, aged 15 months, Pryce Pugh, son of \*William M. Beddoes, M.D.  
 BULLEN. On February 17th, at Ipswich, aged 65, Elizabeth, wife of \*George Bullen, Esq.  
 CRAVES. On February 22nd, at Hull, aged 62, Anne, widow of the late Robert Craven, Esq., Surgeon.  
 JAMES, Job, Esq., Surgeon, at Pontmorlais, Merthyr Tydfil, aged 74, on February 11.  
 JONES, William H., M.D., Staff-Assistant-Surgeon Royal Army, at Torquay, aged 24, on February 11.  
 LOVETT, Samuel, Esq., Surgeon, at 23, Clare Street, Lincoln's Inn Fields, aged 58, on February 19.  
 \*MARTIN, George W., Esq., at Rochester, aged 25, on February 19.  
 MONTGOMERY, Andrew, Esq., late Inspector-General of Hospitals, Bombay Army, at Bath, aged 69, on February 16.

THE INCOME-TAX. Petitions for a readjustment of the income-tax have been presented to the House of Commons from the Royal Colleges of Physicians and of Surgeons, and from numerous practitioners in London.

ROYAL SOCIETY OF EDINBURGH. Dr. J. G. Wilson, of Glasgow, and Dr. Matthews Duncan, of Edinburgh, have been elected Fellows of the Royal Society of Edinburgh.

A DIFFERENCE. Thirty-two firms sent in tenders for the Carmarthen Lunatic Asylum, ranging from £24,950 up to £45,944, and this with quantities supplied. (*Builder*.)

SOCIAL SCIENCE ASSOCIATION. At a meeting of the council of the association, held on Thursday last, Lord Brougham was unanimously elected president for the next annual meeting, which will be held in Edinburgh in October.

BETTER TREATMENT OF THE INSANE IN VICTORIA. The Government purposes bringing in a bill for the better treatment of the insane. In addition to several new asylums, every hospital in the country districts will have a ward for the reception of patients suffering from the disease in the first stage.

DR. MORTON, the alleged discoverer of the application of ether to practice, has again appealed to congress for compensation for the use of this agent in the army. It will be remembered that a similar claim was pressed through both houses several years ago, but failed to obtain the president's signature.

THE MIDLAND SOCIETY OF CHEMISTS AND DRUGGISTS. The first annual dinner of the members of this society was held at Nottingham on the 12th instant, covers being laid for about seventy gentlemen, under the presidency of V. Wilcockson, Esq. The society is formed for the interchange of sentiment on the trade and the protection of interests. (*Nottingham Daily Express*.)

ROYAL COLLEGE OF SURGEONS. Professor Huxley, F.R.S., who is lecturing to a crowded audience in the theatre of the above institution, will deliver his sixth lecture this day (Saturday). Bishop Colenso has attended all the lectures, in which he appears to take a great interest. A lecture will be given on Monday preceding the royal marriage day, instead of on that day.

UNIVERSITY OF DUBLIN DEGREES. On the 17th inst., on the occasion of the installation of the Earl of Rosse as Chancellor of the University, the Degree of Doctor of Medicine was conferred, *honoris causa*, on Dr. Mackesy, the President of the Royal College of Surgeons of Ireland; Dr. Arthur Jacob, Professor of Anatomy and Physiology; and Dr. Butler, Chairman of the Court of Examiners in the College.

HOSPITAL RATIONS IN THE FEDERAL ARMY. The value of the hospital ration supplied to the sick of the Federal army has been hitherto eighteen cents per day. It is now raised to thirty cents per day. The patients have, it appears, been hitherto kept on starvation prices in the Yankee hospitals. "Senator Ten Eyck's remarks," says the *American Medical Times*, were, we fear, nearer the truth: "In some cases the meat set before the sick soldiers was not fit to eat, and he believed that many had actually died from lack of proper food."

ENTERTAINMENT OF LUNATICS. On Friday week, Dr. Paul, of Camberwell House, gave an evening entertainment to a large party of visitors, and to about a hundred and fifty of the lunatics under his care. The proceedings consisted of an amusing lecture on Wit and Humour, by Dr. Richardson; together with songs and glees, and a dramatic performance, by amateurs. The effect of such entertainments on the mental condition of those for whom they are devised must be of a very beneficial character.

UNIVERSITY COLLEGE, LONDON. At a session on Saturday last, the Council of this College filled up the vacant offices of physician and of Professor of Clinical Medicine at the Hospital, by the appointment of Dr. Hare; they also appointed Mr. Sidney Ringer to the vacant Professorship of Materia Medica. By the recommendation of the Senate of the College, the Council invited Dr. Walshe, lately Professor of the Principles and Practice of Medicine, to assume the title of Emeritus Professor.

A HÆMORRHAGIC FAMILY. The son of a brewer's servant died at 1, Elizabeth Place, Ratcliff, by "hæmorrhage from a wound in the head, caused by a shell falling on him from the mantel-piece." (Inquest.) The coroner adds, in his report to the Registrar, that the mother has lost five children in this way, two of whom died in the London Hospital from a scratch in the hand. If they bled but the smallest quantity, they die. Dr. Arnold states that this is the consequence of a hæmorrhagic diathesis. (*Registered Reports*.)

THE AMERICAN ARMY AND HOMŒOPATHS. The homœopaths have again appealed to congress to experiment with infinitesimals in the treatment of sick soldiers, and the committee to whom their petition was referred has asked to be discharged from its consideration. It was not surprising that homœopaths should clamour for recognition while a homœopathic commanding general was its patron; but now that he is superseded, and the medical staff is being thoroughly purged of all its incompetents, it is remarkable that the advocates of this delusion should presume to ask admission to the medical service. They would, if admitted, meet with a summary dismissal.

HONOURS OF WAR. Rear-Admiral Dupont, in his official despatch on the Confederate attack on the Federal squadron off Charleston, writes:—"On the *Keystone State* about one-fourth of her crew were killed or wounded, and among the former is the medical officer of the ship, Assistant-Surgeon Jacob H. Gotweld, who was scalded to death while rendering surgical aid to one of the wounded men. Most of those who died perished from the escape of steam when the boilers and steam chimneys were penetrated, and among the wounded the greater number received their injuries from the same cause."

THE LAW OF LUNACY. In the House of Commons on Monday last, Mr. Butt asked the Secretary of State for the Home Department whether his attention had been called to the recent case of "Hall v. Semple," in the Court of Queen's Bench, and whether it was his intention to propose any alteration in the law relating to certificates required in cases of alleged insanity. Sir G. Grey was understood to say that the case in question did

not, in his opinion or that of the Lunacy Commissioners, disclose any necessity for the alteration of the law, because the law in that case was not observed. The certificate, on the face of it, was an irregular one, and not in conformity with the law. The Lunacy Commissioners had censured the keeper of the asylum, and they had addressed a circular to the proprietors of licensed asylums, calling their special attention to the matter; and it was hoped that the circular and the verdict in this case—assuming that it would be sustained—would prevent the recurrence of such a case.

**ST. BARTHOLOMEW'S HOSPITAL.** A large meeting of the governors of this institution was held on Wednesday in the Board-room, to elect a president in the vacancy occasioned by the resignation of Mr. Cubitt, who, it may be remembered, held office, but resigned it when he dissolved his connection with the City, at the same time intimating that his resignation was owing to the objections started by others rather than the free exercise of his own will. The Lord Mayor was put in nomination, and Mr. Cubitt was then proposed for reelection, and on the votes being taken was declared to be elected by a majority of eighty-seven votes over forty-four.

**THE LEVÉE.** The following members of the medical profession attended the *levée* of H.R.H. the Prince of Wales on Wednesday, held by command of Her Majesty; namely, Sir Rutherford Alcock, K.C.B., Her Majesty's Envoy Extraordinary and Minister Plenipotentiary in Japan; Sir Henry Holland; William Lawrence, Esq.; William Fergusson, Esq.; Drs. Lavies, Pickford, Dalton, Arthur Farre, Cape, Jeaffreson, J. S. Bushnan, T. De Meschier, E. A. Parkes, G. T. D. Evans, F. G. Read, Breslin, E. Meryon, Robert Fergusson, Farr, Watson, Granville, Ramsbotham, Bryson, Gooden, Smith, Waller Lewis, Forbes Winslow, Gideon Dolmage, T. G. Balfour, Marsden, McCann, Ashley, Kirkman, Fraser, Routh; Professor Owen, Deputy-Inspector General Thomas Langmore; and Messrs. Wakley, Reeves Traer, White Cooper, R. W. Tamplin, Dendy, W. S. Cox, Propert, T. Fitzgerald, B. E. Brodhurst, S. S. Scriven, G. B. Childs, Judd, Erasmus Wilson, R. McCormick, R.N.

**POISONOUS MILK.** The occupants of two of the principal hotels of Valetta, in Malta, besides a number of inhabitants of that town, were recently seized with violent symptoms of cholera one morning after breakfast. As, on inquiry, it was found that the only article of diet taken in common by the persons attacked was milk, the inference was that that article contained the poisonous ingredient. Similar cases had occurred before in the island; towards the end of last year the family of a field-officer at Tliema, with the exception of one person, was so affected, as was supposed by goat's milk, and cases of illness occurred among the officers and men of several of Her Majesty's ships then at Malta, none of which, however, terminated fatally. The natives attribute the result to the goats browsing upon a particular plant belonging to the family of Euphorbiaceæ, or spurge-worts, which they call *tenhuta*, and which they say possesses the property of rendering the milk poisonous to human beings without inflicting any injury on the animals themselves. The governor of the island has ordered an inquiry to be instituted.

**THE HOSPITALS OF BETHLEHEM AND ST. THOMAS.** A meeting of the governors of Bridewell and Bethlehem was held last week, for the purpose of considering a proposal on the part of the governors of St. Thomas's Hospital for the purchase of the edifice now occupied by the lunatic patients of Bethlehem. The proceedings were very animated, and the discussion at times warm; Mr. P. N. Laurie denouncing in strong terms the site at Thornton Heath, known as Peake's Land. Mr. Alderman Phillips spoke in favour of entertaining the proposal which had been made by the governors of St. Thomas's,

and brought forward a resolution to the effect that the object of removing the patients of Bethlehem Hospital into the country be taken into consideration. The motion was seconded by Mr. Alderman Finnis. Dr. Webster, in supporting the motion, referred to the asylums for the insane now in course of erection in different parts of Europe, all of which were being removed from towns into rural districts. He had recently visited Madrid, Copenhagen, Stockholm, and other cities, where he observed new buildings in progress of erection for the insane which were superior to any in England. Bethlehem, he said, was well placed fifty years ago; for its present purpose both the building itself, as well as the locality in which it stood, were not in keeping with the improved treatment of the insane. He particularly dwelt on the insane hospitals of Ghent as an example for the governors of Bethlehem, and in an address of some length laid before the meeting most important information for their guidance. Sir John Musgrove also spoke on the same side, and ultimately the meeting came to an agreement that the proposal of St. Thomas's be received.

**A SAD DEATH.** It is with real pain that we have to announce to our readers the death of Mr. Lucas Barrett, the distinguished naturalist, who was accidentally drowned whilst investigating the structure of some coral reefs at Port Royal, Jamaica. All who visited the Jamaica Court at the International Exhibition will remember the enthusiasm and painstaking kindness with which this gentleman was ever ready to show and explain the various mineral and geological specimens collected and exhibited by him. Although one of the most active of the Jamaica Commissioners, he still found time to officiate as one of the local secretaries of the British Association, besides keeping a term at Cambridge. Before returning to Jamaica to renew his researches as one of the chief members of the West Indian Geological Survey, he ordered a diving dress and pumping apparatus of the latest and most scientific construction, for the purpose of personally examining the rocks and coral reefs lying in the neighbourhood of most of the West India islands. He first tried this dress at Port Royal, on December 17, in shallow water, and was so well pleased with the result that he determined to give it a trial in deeper water. Two days afterwards he took with him his servants and boat's crew, all of whom were negroes, and descended into the deep water between the reefs. The men in the boat continued to pump without intermission as on the former occasion, but they noticed that he remained longer in the water than usual. Suddenly, to their horror, they saw him floating on the surface at a little distance from the boat. They got to him as quickly as possible, but all was over. The cause of his death will remain a mystery. He was not drowned by the influx of the water, as the diving dress contained only air. The only explanation to be given is, that the air exit valves became permanently closed in some mysterious manner; but even this seems open to doubt, as the men continued to pump without interruption. Mr. Barrett, was only twenty-five years of age when he died; and the enormous amount of valuable work done by him during his brief career, gave promise of his speedily becoming one of the chief ornaments of the science he so ardently loved, and to the too enthusiastic pursuit of which he fell a victim. For three years before his engagement on the West Indian survey, he delivered most of the geological lectures for Professor Sedgwick, and was made by him curator of the Woodwardian museum at that university. His collection of *Radiata* in that museum is one of the finest in the world. (*Chemical News.*)

**RUSSELL *versus* ADAMS.** A numerously attended meeting of the members of the medical and legal professions and other persons took place, on Tuesday last, at the Freemasons' Hall, Great Queen Street, for the purpose of expressing an opinion in the case of *Russell v. Adams*.

The chair was taken by Mr. W. E. Forster, M.P. He observed that it was gratifying to find that so large a number of gentlemen whose time was of value had met together to do an act of justice to a brother practitioner who had been unjustly assailed. He gave a brief recapitulation of the recent case, observing that, although it was tried in a civil court, yet the accusation against the defendant, that he had sought to use his professional position as a means of gratifying his passions, really amounted to a criminal charge. Ninety-nine out of every hundred men who had paid any attention to the trial were of opinion that Mr. Adams was entirely innocent; but he presumed that the other hundredth man must have been in the jury-box, and that the equivocal verdict returned was but a compromise. That verdict rendered necessary a new trial at the bar of public opinion, which was quite as serious, and involved as important consequences to Mr. Adams. The result of this second trial had been a complete and conclusive acquittal; but the necessity for publicly declaring this still remained. It was only by his own benevolence that Mr. Adams had laid himself open to the disgraceful charge brought forward; and no one indeed, however pure his conduct or exalted his character, could be considered free from similar perils. The danger applied, not only to the medical profession, but to society at large. Crime is infectious; and such accusations might again be made. Alterations in the law were, he knew, desired by some of the gentlemen present; but no legal reform that might be made would supersede the necessity for expressions of public opinion.—The following resolutions were unanimously passed:—1. Proposed by Dr. Lankester, and seconded by Dr. Joseph Rogers: "That all classes of society are interested in supporting those who incur great trouble, annoyance, and expense by resisting and exposing any attempt to injure their character by false charges."—2. Proposed by H. H. Cannan, Esq., and seconded by Dr. Richardson: "That a careful consideration of the charge of the judge, and of the evidence adduced, in the case of Russell v. Adams, should have led to an unqualified verdict for the defendant."—3. Proposed by W. L. Leaf, Esq., and seconded by Spencer Wells, Esq.: "That this meeting offers to Mr. Adams a vote of thanks for his manly conduct in courting the fullest public investigation into his conduct; expressing deep regret at the annoyance to which he has been subjected, and firm conviction that there was nothing in his behaviour which gave the slightest ground for any charge against him."—4. Proposed by J. Dangerfield, Esq., and seconded by John Churchill, Esq.: "That a petition be presented to Parliament, praying that a committee may be appointed to inquire into the reforms necessary in the present legal procedure; and praying especially that greater facilities may be given for prosecuting persons who make unfounded attacks upon character."—A correspondence between Mr. Mackrill, the solicitor to Mr. Adams, and Mr. Propert, was read, in consequence of a report that Mr. Propert had backed up Mrs. Russell in her proceedings against Mr. Adams. The correspondence certainly seemed to indicate that Mr. Propert had at some period of the proceedings been a warm partisan of Mrs. Russell. We do not, however, think it necessary to publish the letters, because Mr. Propert, in the following lines (which were also read at the meeting), gave the most unqualified contradiction to the insinuation which had been made:—"6, New Cavendish Street, Feb. 24th, 1863. My dear Churchill,—I think after the many years of uninterrupted friendship that has existed between us, you might strain a point to defend the hard-working Welshman; that is, *provided* you should have it said to-day at the meeting that I had brought the action, Russell v. Adams; when I say, so help me God, I had nothing to do with it; proceedings had been begun for *months* before I ever knew that such people existed in the world as Mrs. Russell and her beautiful

daughter; and that I never contributed, or ever promised to contribute, one farthing towards the expenses of the trial. Ever most truly yours, JOHN PROPERT. J. Churchill, Esq."—The following letter from Mr. Lush, Q.C., indicates very clearly what was the real opinion of the Lord Chief Baron on the case:—"60, Avenue Road, Feb. 20th, 1863. My dear sir,—Pardon my delay in answering your kind favour, for which I thank you heartily. I can truly say I never was engaged in a case that gave me more anxiety; because I felt convinced that you were the victim of a foul conspiracy. It is a great comfort to me to know that my client is satisfied I did my best. There is but one opinion, in and out of court, as far as I can learn, as to the injustice done to you. Notwithstanding the inaccuracy and clumsiness of the report in the *Times*, the case, as reported, has impressed every one whom I have heard express an opinion on the subject, with the conviction that the verdict ought to have been entirely in your favour. I wished to know from the Chief Baron, before I advised you what to do, what his views were. I saw him yesterday. He complains, as I do, of the report of his summing up, and of the great injustice done to you by it; and when I told him that I meant to advise your publishing a shorthand, authentic, report of it *in extenso*, he at once said he hoped you would do so, and that he would revise it if I wished before sending it to the press. This I think you should do at once. Send it to me, and I will hand it to the Chief Baron. I am rejoiced to find that the medical body are taking it up. I have told more than one of that body that they ought to do so. I hope you will not—I do not think you will—suffer permanently from this unaccountable verdict. Believe me, my dear sir, yours very truly, B. W. LUSH. W. Adams, Esq."

## Varieties.

WIESBADEN MINERAL WATERS. Perhaps no part of the world contains, within so small a compass, so many valuable mineral waters as this duchy of Nassau. Nor would it be easy to find a greater variety of beautiful scenery. Its thermal springs are described by Pliny in his *Natural History*, and there is no reason to doubt but they have been known and highly prized from a very remote antiquity. This certainly is a highly favoured country in many respects. Its soil is fertile; its climate is admirable; its inhabitants intelligent, temperate, honest, and industrious; education, being compulsory, is universal; begging prohibited; taxes light; peace and plenty everywhere abound. This small duchy would seem to embrace an epitome of all the medicinal springs of the world; at Weilbach *e. g.* we have the sulphur; at Sollen, the cold saline; at Kronthal, the acidulous and chalybeate; at Baden and Wiesbaden, the hot saline; at Homburg, the cold saline and chalybeate; at Swallbach, the chalybeate; at Ems, the hot alkaline; the same at Solhlagenbad, etc. (*Prof. C. Lee.*)

THE "PERFECT CURE." A paper has been sent in to the French Academy of Sciences by Dr. Tridan of Laval, containing a most important discovery, if it is really so efficacious as the author asserts:—"In the midst of a severe epidemic," he says, "of diphtherite, which carried off from two to three hundred persons in the canton of Chaillant (Mayenne), I was struck with the idea of employing some powerful modifier of the mucous membrane, of a nature to change its vitality, and I selected copahu and stryax. From the first day I used them, I have cured five cases of croup and forty of diphtheritic angina (sore throat), in the course of about five months and a half. I have only lost a single patient. In most cases the improvement takes place within twenty-four

hours: the cure is usually effected within four or six days. I use copahu under the form of a syrup (Dr. Puche's formula), or else in a solid state. I also use the syrup of styrax of the codex. For adults, I prescribe a tablespoonful of copahu syrup every two hours, alternating with the syrup of styrax, also taken every two hours. For children, I prescribe teaspoonfuls taken in the same manner. In serious cases, the patient takes five grammes of copahu under the form of an enema twice a day. Copahu is generally well borne by the patient so long as the disease is not conquered."

**MUMMY WHEAT.** The *Presse Scientifique des Deux Mondes* contains a description of a series of experiments made in Egypt by Figari-Bey on the wheat found in the ancient sepulchres of that country. A long dispute occurred a few years ago, as to what truth there might be in the popular belief, according to which this ancient wheat will not only germinate after the lapse of three thousand years, but produce ears of extraordinary size and beauty. The question was left undecided; but Figari-Bey's paper, addressed to the Egyptian Institute at Alexandria, contains some facts which appear much in favour of a negative solution. One kind of wheat which Figari-Bey employed for his experiments had been found in Upper Egypt, at the bottom of a tomb at Medinet-Abou, by M. Schnepf, Secretary to the Egyptian Institute. There were two varieties of it, both pertaining to those still cultivated in Egypt. The form of the grains had not changed; but their colour, both within and without, had become reddish, as if they had been exposed to smoke. The specific weight was also the same—viz., twenty-five grains to a gramme. On being ground, they yield a good deal of flour, but are harder than common wheat, and not very friable; the colour of the flour is somewhat lighter than that of the outer envelope. Its taste is bitter and bituminous; and when thrown into the fire, it emits a slight but pungent smell. On being sown in moist ground, under the usual pressure of the atmosphere, and at a temperature of 25 degrees (Reaumur), the grains became soft, and swelled a little during the first four days; on the seventh day, their tumefaction became more apparent, with an appearance of maceration and decomposition; and on the ninth day, this decomposition was complete. No trace of germination could be discovered during all this time. Figari-Bey obtained similar negative results from grains of wheat found in other sepulchres, and also on barley proceeding from the same source; so that there is every reason to believe that the ears hitherto ostensibly obtained from mummy wheat proceed from grain accidentally contained in the mould into which the former was sown.

**STATISTICS OF THE GLOBE.** The following curious facts are stated by the *Abeille Médicale*:—The earth is inhabited by 1,288 millions of inhabitants, viz., 369,000,000 of the Caucasian race; 552,000,000 of the Mongolian race; 190,000,000 of the Ethiopian, 1,000,000 of the American Indian, and 200,000,000 of the Malay races. All these respectively speak 3,064 languages and profess 1,000 different religions. The amount of deaths per annum is 333,333,333, or 91,954 per day, 3,730 per hour, 60 per minute, or 1 per second. This loss is compensated by an equal number of births. The average duration of life throughout the globe is 33 years. One-fourth of its population dies before the seventh year, and one-half before the seventeenth. Out of 10,000 persons only one reaches his 100th year; only one in 500 his eightieth, and one in 100 his sixty-fifth. Married people live longer than unmarried ones; and a tall man is likely to live longer than a short one. Until the fiftieth year women have a better chance of life than men; but beyond that period the chances are equal. Sixty-five persons out of 1,000 marry; the months of June and December are those in which marriages are most fre-

quent. Children born in spring are generally stronger than those born in other seasons. Births and deaths chiefly occur at night. The number of men able to bear arms is but one-eighth of the population. The nature of the profession exercises a great influence on longevity; thus out of 100 of each of the following professions the number of those who attain their 70th year is: Among clergymen, 42; agriculturists, 40; traders and manufacturers, 33; soldiers, 32; clerks, 32; lawyers, 29; artists, 28; professors 27, and physicians, 24, so that those who study the art of prolonging the lives of others are most likely to die early, probably on account of the effluvia to which they are constantly exposed. There are in the world 335 millions of Christians, 5 millions of Jews, 600 millions professing some of the Asiatic religions; 160 millions of Mahometans, and 200 millions of pagans. Of the Christians, 170 millions profess the Catholic, 76 millions the Greeks, and 80 millions the Protestant creeds.

#### OPERATION DAYS AT THE HOSPITALS.

**MONDAY.**.....Royal Free, 2 P.M.—Metropolitan Free, 2 P.M.—St. Mark's for Fistula and other Diseases of the Rectum, 1.15 P.M.—Samaritan, 2.30 P.M.—Lock, Clinical Demonstration and Operations, 1 P.M.  
**TUESDAY.**.... Guy's, 1½ P.M.—Westminster, 2 P.M.  
**WEDNESDAY.**.. St. Mary's, 1 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.  
**THURSDAY.**.... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—London, 1.30 P.M.—Great Northern, 2 P.M.—London Surgical Home, 2 P.M.—Royal Orthopaedic, 2 P.M.  
**FRIDAY.**..... Westminster Ophthalmic, 1.30 P.M.  
**SATURDAY.**.... St. Thomas's, 1 P.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.

#### MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**MONDAY.** Medical Society of London, 7 P.M., General Meeting for Election of Officers and Council; 8.30 P.M., Dr. Routh, "On some Points in the Treatment of Prolapsus Uteri."—Entomological.—Asiatic.—Royal Medical and Chirurgical (Anniversary).—Epidemiological Society, 8 P.M. Dr. Smart, R.N., "On the Successive Epidemics of Malignant Fever in Bermuda."  
**TUESDAY.** Pathological.—Photographical.—Ethnological.  
**WEDNESDAY.** Royal College of Physicians, 5 P.M. Dr. Risdon Bennett. Croonian Lectures. "On some Points connected with Bronchitis, and its Results."—Obstetrical Society of London, 8 P.M. Dr. Shortt, "On Woman's Life in Southern India"; Dr. Clay, "Observations on Ovariotomy, Statistical and Practical; also, a Successful Case of Entire Removal of the Uterus and Appendages"; Dr. Broadbent, "On Displacement of the Bladder as a Cause of Tedious Labour."—Society of Arts.—Geological.  
**THURSDAY.** Royal.—Antiquarian.—Linnean.—Chemical.—Harveian.  
**FRIDAY.** Royal College of Physicians, 5 P.M. Dr. Risdon Bennett. Croonian Lectures. "On some Points connected with Bronchitis, and its Results."—Royal Institution.—Archæological Institute.—Western Medical and Surgical, 8 P.M., "Practical Evening for the Narration of Cases and the Exhibition of Specimens."  
**SATURDAY.** Medical Society of London (Anniversary). 5 P.M., Oration by Dr. Habershon; 6.30 P.M., Dinner.

#### POPULATION STATISTICS AND METEOROLOGY OF LONDON—FEBRUARY 21, 1863.

[From the Registrar-General's Report.]

	Births.		Deaths.	
During week.....	{ Boys.. 1012		1903	1377
	{ Girls.. 896			
Average of corresponding weeks 1853-62 .....			2030	1464
<b>Barometer:</b>

Mean humidity of air (saturation=100), 86.				
Mean direction of wind, S.E. & S.W.—Rain in inches, 0.19.				

## TO CORRESPONDENTS.

\*. All letters and communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen St., Lincoln's Inn Fields, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

MR. COOMBE AND HOMŒOPATHY.—In reply to Mr. Coombe, all we have to state is this:—Mr. Coombe has been publicly accused of practising homœopathy; consequently, there is only one possible way in which he can purge himself of the accusation and its attendant good or evil; and that is by publicly saying, he never has had, or if he has had, that he will in future have no further connexion with the thing. His letter does neither the one thing nor the other, and therefore we see no good to be derived from its publication.

DR. KIDD ON ASCARIDES.—Dr. Kidd writes to us to the following effect:—

"He feels aggrieved that a letter of his in this JOURNAL about a year since, on Ascarides in Children, subsequently noticed at the last meeting of the British Association at Cambridge, has been misrepresented in the *Lancet*, and he has been refused any explanation. Dr. Kidd adheres to what was stated in this JOURNAL; so that his truthfulness has only been questioned on *ex parte* letters. Science cannot be much advanced by hole and corner one-sided views. Dr. Kidd's theory is, that what are often treated as 'ascarides' by tin filings, cowhage, chloroform injections, etc., are larvae of the blow-fly and other flies, something like 'bots' in the lower animals; and that the true remedy must be of a prophylactic kind. He did not say, as now suggested, that one is changed into the other, as may be perceived by referring to the original letters."

SEVERAL LETTERS on the "Title of Doctor" and on "Gratuitous Medical Services" are unavoidably delayed until next week.

DR. WALKER'S reports of surgical cases will be published soon.

## SUBSCRIPTIONS.

THE following Laws of the Association will be strictly enforced:—

15. The subscription to the Association shall be One Guinea annually; and each member on paying his subscription shall be entitled to receive the publications of the Association of the current year. The subscriptions shall date from the 1st of January in each year, and shall be considered as due unless notice of withdrawal be given in writing to the Secretary on or before the 25th of December previous. If any member's subscription remain unpaid twelve months after it shall have become due, the publications of the Society shall be withheld from such member until his arrears be paid.

16. The name of no member shall remain on the books of the Association, whose arrears extend over three years; but the omission of the name from the list of members shall not be deemed, either in honour or equity, to relieve any member from his liability for the subscriptions due for the period during which he has availed himself of the privileges of membership.

PHILIP H. WILLIAMS, M.D., General Secretary.

Worcester, February 1863.

COMMUNICATIONS have been received from:—Dr. J. HUGHES BENNETT; Dr. F. J. BROWN; THE HONORARY SECRETARY OF THE OBSTETRICAL SOCIETY OF LONDON; Mr. A. B. STEELE; Dr. JAMES RUSSELL; Mr. F. T. PONCIA; Dr. OGLE; THE REGISTRAR OF THE MEDICAL SOCIETY OF LONDON; Dr. COPEMAN; Dr. LIONEL BEALE; Mr. SAMUEL WOOD; Mr. LOWNDEN; THE HONORARY SECRETARIES OF THE WESTERN MEDICAL AND SURGICAL SOCIETY OF LONDON; Dr. A. T. H. WATERS; Mr. J. SPOURLE; Dr. WILLIAM BUDD; Dr. J. WEST WALKER; F.R.C.S.; THE HON. SECRETARIES OF THE EPIDEMIOLOGICAL SOCIETY; Mr. JOHN JONES; Dr. ASPINALL; and Mr. STONE.

## BOOK RECEIVED.

1. A Treatise on Gall-Stones: their Chemistry, Pathology, and Treatment. By J. L. W. Thudichum, M.D. Illustrated with Plates. London: 1863.

## A Surgeon to a County Hospital

in one of the healthiest Towns in England has a Vacancy for a PUPIL. A youth really desirous of gaining a sound knowledge of his profession will find this an excellent opportunity of doing so. References exchanged.—For terms, etc., address A. B., Messrs. WRIGHT, FRANCIS, & Co., 11, Old Fish Street, London.

## Aërated Lithia Water. —

Messrs. BLAKE, SANDFORD, and BLAKE are prepared to supply the LITHIA WATERS (of which they were the original Manufacturers under Dr. GARROD's instruction) of any strength prescribed by the Profession for special cases. Those in constant use contain two grains and five grains in each bottle, either by itself or combined with BICARBONATE of POTASH or PHOSPHATE of AMMONIA.—Also, Potash, Citrate of Potash, Soda, Seltzer, Vichy, and Mineral Acid Waters, as usual.

BLAKE, SANDFORD, and BLAKE, Pharmaceutical Chemists, 47, Piccadilly.

## Peroxide of Hydrogen. (The

New Medicinal Agent.) According to the formula, and of the strength described by Dr. Richardson in a paper read before the Medical Society.

See *British Medical Journal*, March 22, and other Medical Journals.

Price 4s. 6d. per lb.

Prepared by A. GARDEN, Operative Chemist, 372, OXFORD STREET, LONDON.

FIRST-CLASS SILVER MEDAL. PARIS, 1855.

## S. Nye &amp; Co.'s Small Mincer for

the DINNER TABLE, for those who cannot properly masticate, and who, in order to preserve health, should have their food thoroughly minced. Price 30s.—TESTIMONIAL: "I have had one of your Mincers for the Dinner-table in use for some time, and find it everything that can be wished. I recommend it to all who suffer from indigestion. T. SAUNDERS, Norfolk Villas, Bayswater."

LARGER MACHINES for Public Institutions. Lunatic Asylums, Hospitals, Schools and other establishments, effectually and quickly mincing all kinds of meat and vegetables, for soups, etc., forced and potted meats, and a variety of dishes; also for making sausages, cutting, mixing, and forcing into the skins at the same time. Price 21s., 30s., 42s., 63s., and £7 : 7.

Also MILLS on an improved construction for Coffee, Spice, etc. etc. Depot and Manufactory, 79, Wardour Street, London. W.

## Great Saving in the Purchase

of NEW MEDICAL GLASS BOTTLES and PHIALS, at the NORTH LONDON GLASS BOTTLE WORKS — I. ISAACS and COMPANY (Proprietors). London Warehouse, 24 and 25, Francis Street, Tottenham Court Road, W.C.

6 & 8 oz., any shape, plain or graduated	Clear	8s. 0d. per gross.
3 & 4 oz. ditto	Blue-tinted	7s. 6d. "
1 oz. Moulded Phials		4s. 6d. "
1 oz. ditto		5s. 6d. "
1 1/2 oz. ditto		6s. 0d. "

# Facts and Arguments

OPPOSED TO

## DR. BENNETT'S THEORY OF ORGANISATION.

BY

LIONEL S. BEALE, M.B., F.R.S.

DR. BENNETT does not explain more fully the peculiar views he entertains; but refers me generally to the works of Martin Barry, Meissner, Nelson, Keber, and others (!), and then qualifies his reference by saying, "I do not wish him (Dr. Beale) to regard their *expressed opinions or theories*; but the *facts* they have observed, and some of *which* I copied in my first lecture in the *Lancet*—Figs. 9, 10, 13, 14, and 15."

I know Dr. Bennett has copied the figures of Dr. Nelson; but Dr. Nelson's explanation of his own figures is quite different from Dr. Bennett's. Dr. Nelson says nothing about molecules of the ovary coalescing to form the ovum; nor can I find in his paper any fact, observation, or drawing, in favour of Dr. Bennett's peculiar theory.

Dr. Nelson thus describes the first figure Dr. Bennett has copied from his paper in the *Philosophical Transactions* for 1852, Fig. 44: "Contents of the caecal portion of the ovary—*a*, the germinal spot, which is solid; *b*, the germinal vesicle, transparent, containing a fluid and the germinal spot. The germinal particle is first thrown off, the swelling up of whose outer layer forms the germinal vesicle, while the central portion remains unaltered to form the germinal spot."

Dr. Bennett compresses this description and that of the two following figures into this sentence: "Figs. 9 to 12 represent the *histogenetic changes* (!) which take place among the *molecules deposited* (!) in the ovarian tube of the female worm, until the fully matured ovum passes into the oviduct." Nor does he insert one of the letters of reference! "Among the molecules"! Every separate body represented in Figure 9 is an entire ovulum. Are these "*the molecules which coalesce to form the ovum*"? All interested in this question should compare Dr. Nelson's description of his own figures in the *Philosophical Transactions* for 1852 with Dr. Bennett's explanation of these same figures copied into the *Lancet* of January 3rd, 1863, page 4.

Dr. Bennett complains that I do not point out the errors in detail, and says that unless I abandon "generalities" and "assertions", and become "more particular" in my facts and arguments, he cannot propose to continue the "explanations" to which I invite him.

It certainly appears to me that many statements made by Dr. Bennett are themselves generalities and assertions, and of the most positive kind. This was why I begged for further information.

1. Surely it is but an assertion to say that molecules aggregate together to form vibriones, since neither these molecules nor this aggregation have ever been seen. Because particles of phosphate or carbonate of lime unite, coalesce, or become aggregated together to form larger masses, it by no means follows that living structures are formed by the aggregation of molecules. This is no argument at all,

until it has been shown that things living are governed by the same laws alone as things inanimate—that, for example, in the formation and growth of a living nucleus, and in the precipitation and increase of a particle of inorganic matter, the same, and only the same, forces are concerned.

2. It is an assertion, but simply an assertion, to say that the addition of the force we call *vitality* occurs *after* the molecules have become aggregated together; and I do think that Dr. Bennett is bound, as a scientific man, to give facts and arguments in favour of so peculiar a view, or to abandon it. Would it not be very unreasonable to assert that a tree or an animal was first formed or built up, and was then made to *live*?

3. It is an assertion to say that the perfect worm (*ascaris*) is formed "by a *third act* of histogenetic coalescence." It is an assertion to say that histolytic molecules "meet together, concentrate themselves, and form histogenetic molecules." There is not a shadow of proof in favour of the view that any one molecule, resulting from the disintegration of any substance whatever, becomes a living molecule. A molecule of oil or phosphate of lime may result from disintegration; but as such molecule, it can never live. A *living molecule* of oil, phosphate of lime, or any other substance having a definite known composition, is a simple impossibility. We might as well speak of a living mass of iron, lead, or other metal.

4. It is simply an assertion, and, I maintain, unsupported by evidence, to say "the molecules of the ovary first coalesce to form the ovum"; and Dr. Bennett must permit me to ask him the following questions upon this matter.

*a*. Does the assertion apply to ovaries generally, or to the ovary of *ascaris* mystax alone?

*b*. Does the entire ovary consist of molecules; or is there any tissue?

*c*. Are the molecules free, or imbedded in any tissue?

*d*. How are the molecules of the ovary produced? Do they all appear at the same time? If not, how do they increase in number?

*e*. Do all the molecules of the ovary unite to form one ovum, or are many ova produced? If many ova result, what prevents them from becoming aggregated together to form *one large ovum*?

*f*. Can ova be produced in any other manner than by the aggregation of molecules?

*g*. Has Dr. Bennett himself *seen* the molecules in the ovary of *ascaris*, or studied the changes he describes in the constituent molecules of the ovum of this or any other creature?

*h*. Why does he term some molecules in the ova figured by Dr. Nelson *histolytic*, and others *histogenetic*, as Dr. Nelson himself neither used the terms nor described the changes as Dr. Bennett describes them?

I would also ask if the conclusions Dr. Bennett has arrived at with regard to the disintegration of spermatozooids and germinal vesicle to form *histolytic molecules* are derived from his own observation, or from other authorities, as I am not aware that any one has demonstrated that any molecules whatever result in this case. It is said that the spermatozoa *disappear*; but Dr. Bennett is the only physiologist who has observed (!) that they become molecules.

Dr. Bennett asks: "How can solid matters grow or

increase in extent and density, unless from that very solution solid molecules (!) are thrown down which by aggregation produce bulk?" I answer that, even where pabulum does contain molecules, these molecules are prevented from passing into living matter. Insoluble inanimate particles may be precipitated from solutions, and will become aggregated together to form *inanimate masses*; but all matter serving to nourish living matter must be *in solution*. Where the food is insoluble, it must be reduced to a perfectly soluble condition; and any insoluble matters present are invariably filtered off before it is appropriated by anything living. The vibriones grow and multiply in a solution which is perfectly clear, and in which not a visible molecule besides themselves can be discerned.

These vibriones can hardly be termed *solid molecules*. What then, according to Dr. Bennett, is a solid molecule? Any one who was acquainted with the subject of cell-growth, as explained in modern text-books, might have advanced the same objections, and asked for further explanations upon the very same points. Dr. Bennett must bear in mind that the view he advocates has been advanced by him alone; and he must admit that the *onus probandi* rests with him. His view has now been before observers, both in this country and on the continent, for many years; and surely, if the statements he has made are founded upon facts capable of demonstration, they have been verified and received by many anatomists by this time.

Surely, all anatomists are not so biased as to be incapable of accepting what they can see or what can be shown to them. Dr. Bennett evidently considers that *my objections* result from prejudice in favour of my own views; and, as I am anxious that he should have the advantage of any adverse impression that can be excited upon this head, I will simply reprint Dr. Bennett's question and answer without comment.

"Again, may not Dr. Beale's avowed incapability of comprehending my views originate in the strong bias he possesses in favour of his own doctrines, in consequence of which he is unable to regard mine from an independent point of view? If so, he cannot be expected either to criticise or understand them correctly."

I propose to devote a separate communication to the important question of the development of vibriones, and I thank Dr. Bennett for expressing his views upon this point so definitely.

## HOSPITAL PRACTICE:

METROPOLITAN AND PROVINCIAL.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.

INFANTILE SYPHILIS.

Under the care of J. Vose Solomon, Esq., F.R.C.S.

CASE. *Primary Syphilitic Ulcer of the Eyelid in an Infant Eight Months old, followed by Secondary Symptoms; Inoculation of the Breast of the Mother, followed by Secondary Symptoms.* On the 11th of September, 1860, an infant (L. L.), 8 months of age, was admitted under the care of Mr. Solomon, for a small unhealthy ulcer, with an indurated base, situated at the inner extremity of the lower lid, close to the roots of the eyelashes. It had been there a fortnight.

The child was somewhat strumous-looking, fairly nour-

ished, and could not be said to be unhealthy. It had not suffered from "snuffing" or any sort of disease. The mother, who brought the patient to the hospital, was in appearance healthy, and close questioning failed to elicit a syphilitic history. The father also was healthy, and denied having suffered from sore-throat, falling off of the hair, or disease of the skin. The ulcer on the infant was considered by Mr. Solomon to be syphilitic; but, in the face of the foregoing facts, soothing topical applications only were ordered. In three days later, no amendment having taken place, quinine was ordered, and the sore to be dressed with diluted citron ointment. Change for the worse, rather than the better, having taken place, inquiry was made whether any one had been in the habit of nursing or fondling the child who was suffering from a skin-eruption or sore-throat. It was replied, "Yes; her aunt is so affected." When this lady presented herself at the hospital, she was found to be covered with copper-coloured blotches; and her tonsils were fissured with ulcers, which afforded a discharge. These diseases had been attributed to bathing in the sea, and permitted to run a natural course. The inference Mr. Solomon drew from this examination was, that the aunt, in kissing the infant, had inoculated its eyelid. The inner extremity of the lid, close to the muco-cutaneous margin, is, according to his experience, more susceptible to primary syphilis than any other part of the palpebra. Any one who has once seen syphilitic tubercle of the eyelid could not mistake it for a primary ulcer.

Small doses of mercury were now given twice a day, in combination with Dover's powder and sugar. Nevertheless, on the 28th of September, six weeks from the first appearance of the primary affection, which had healed, the child's buttocks presented well-marked syphilitic blotches; and on the 23rd of October, a rather large, ill-conditioned, and deep ulcer had invaded the external labium. Syrup of iodide of iron had been ordered on the 19th, in addition to the mercury, which was given once a day only.

After a while the child's mouth presented a fissure at its commissure. An ulcer appeared on the mother's breast, and she had secondary symptoms.

The case of the infant was carefully watched by my friend and late pupil, Mr. Walker, now of the firm of Bull and Walker, of this town; and that of the mother by Mr. Baines, who attended the family, and to whom the case was referred for treatment.

REMARKS. The fact of this little patient having attained nearly the eighth month of its age before the appearance of the primary chancre, excludes all grounds for believing that the disease was contracted during the parturient process. How then was the inoculation effected, and from what source?

The answer is found in the common practice among some women of fondling children, by *sputtering* upon their faces, and, so strange is taste, upon the genitals and nates of infants. By these acts, the secretions of the mouth are frequently deposited upon the place of contact. It was probably in this way that the discharge from the aunt's tonsils was conveyed to the eyelid of her infant niece.

In opposition to this theory, we have the high authority of Dr. Diday, who declares he has been unable to discover evidence of the occurrence of a primary syphilitic sore as a result of inoculation from a secondary disease. The case before us is, in this respect, *unique*, inasmuch as the affection of the mouth of the suckling was a secondary non-congenital disease, and by it the nipple of the mother was inoculated. The specific character of that infection having been placed beyond dispute by the occurrence of secondary symptoms. We therefore conclude that the discharge from a secondary sore has given rise to a syphilitic ulcer, which, in its turn produced secondary symptoms.

### OBSERVATIONS ON THE OCCURRENCE OF MALIGNANT PUSTULE IN ENGLAND: ILLUSTRATED BY NUMEROUS FATAL CASES.

By WILLIAM BUDD, M.D., Clifton; Honorary and  
Consulting Physician to the Bristol Royal  
Infirmary.

"Le médecin doit, dans ses premières études, jeter un coup d'œil  
sur les animaux qui se rapprochent le plus de l'homme."—*Chaus-  
sier*. (Adopted from Régnier.)

[Continued from page 161.]

As I have never had an opportunity of observing this  
malady on the continent, where its characters are well  
known and universally recognised, it may perhaps be  
expected that I should state the grounds on which I  
have been led to identify the foregoing cases with it.

To those who have once seen a case of this kind, and  
are also acquainted with the literature of malignant pus-  
tule, these grounds must be sufficiently obvious.

Foremost among them stands the seat of the malady  
in the subjects whose histories have here been given.  
It can scarcely fail to strike every one as, in all ways, a  
deeply significant fact that in the whole series the parts at-  
tacked were the only parts of the body which in this  
country are habitually uncovered. Had the face been  
the only part to suffer, the case had been less striking.  
In that event, it might have been argued with some  
plausibility, however erroneously, that the course and  
chief characters of the disease had their root in some  
structural peculiarity. But the fact that in the only  
two in which the pustule did not appear in the face, it  
appeared in the hands, and in the hands, too, of working  
people, getting their living by manual labour, not only  
excludes this idea, but renders the meaning of the whole  
history difficult to misinterpret. We have already seen  
what stress the continental writers lay upon this charac-  
teristic as suggestive of inoculation from without. But  
whatever its import may be, as a part of the natural  
history of malignant pustule, it has not only obtained  
universal recognition, but has been put in the foremost  
rank by all the best observers.

"Immer erscheint der (milzbrand) Karkunkel an unbe-  
deckten Stellen."—"Malignant pustule always appears  
on uncovered parts"—is the universal remark of the  
German writers.

"It is never seen but in the face, neck, and hands;  
in parts, finally, which are habitually uncovered, and  
which lie open to the impression of an external agent"  
—is the pointed expression of Enaux and Chaussier.

Speaking of the different points which malignant pus-  
tule may attack, Bourgeois says:—"These points are, in  
the immense majority of cases, seated on those  
parts which are habitually uncovered, and which, in  
consequence of this, may easily be put into relation  
with the numerous vehicles of this malignant virus."

In another passage he adds:—"The application of  
the charbon virus to the skin being indispensable to the  
development of malignant pustule, it is readily con-  
ceived why the uncovered parts of the body should be  
its almost exclusive seat; thus, the face, the neck, the  
hands, the arms, and the legs, are almost the only parts

on which it appears. When by chance it develops it-  
self on other parts, we may be sure that the poison has  
been carried there directly by the fingers or other agents  
impregnated with it."

In one form or another, these statements are echoed  
by every foreign writer of any eminence who has treated  
of the malady. But if the foregoing cases agree with  
malignant pustule in a peculiarity so significant as that  
here defined, their agreement with it in all that regards  
the course and character of the morbid changes is not  
less striking. The more, in fact, we enter into detail in  
pursuing our comparison between the two things, the  
more perfect their identity becomes. To one of two  
alternatives, indeed, this comparison necessarily drives  
us. Either the cases which have been described in this  
paper are identical with the specific disease which  
Chaussier, Bourgeois, and others, have described under  
the name of malignant pustule, or it is not possible to  
convey a knowledge of a disease, striking beyond most  
others, by description at all.

The phenomena which these cases exhibited, from  
their first minute beginning to their terrible and unex-  
pected end, were, in every particular, identical with those  
which, in farriers and others who have the charge of  
cattle in continental countries, have been seen, in num-  
berless instances, to proceed from the accidental but  
direct inoculation of the "charbon" virus.

The commencement of the disease in an affection re-  
sembling the bite of a gnat, and, at first sight, not at  
all more serious, in outward seeming—the importunate  
itching or the equally characteristic stinging and burn-  
ing of the early stage—the formation, within a few  
hours of the well known vesicle—the hardening, blacken-  
ing, and death (the "mummification," as the French and  
Germans express it) of the textures immediately around  
it—(hardening so extreme and death so entire that in  
more than one instance the knife of the surgeon creaked  
in the flesh, inflicted no pain, and gave issue to no  
blood)—the diffuse and erysipelatous swelling of the  
wider area—the crop of secondary vesicles—the chains  
of inflamed lymphatics—the factor of the breath—and,  
lastly, death amid all the indications of septic poisoning  
—were incidents common to them all. In the one or two  
cases, indeed, in which some of these circumstances fail,  
I have especial reasons for believing that their absence  
from the record is simply due to their not having been  
noted.

Taken in their whole succession, it may be safely  
affirmed that these are incidents which are diagnostic of  
malignant pustule, and belong to no other malady. Its  
characters in its advanced stage are, in fact, so marked  
and distinctive that to confound it with any other dis-  
ease would seem to be well nigh as impossible as it  
would be to do the same with small pox or glanders.

Striking as are the positive signs, the negative signs  
are scarcely less so. Among these, especially noteworthy  
for a malady so rapid and severe, are the absence or  
slightness of pain, and still more so, the entire absence  
of common suppuration. In not one of the whole series  
of cases was there any visible trace of pus. These  
things are important, not only because they are well  
known and distinctive characteristics of malignant pus-  
tule, but because they have no doubt a fundamental re-  
lation, as such, to the peculiar mode of action of the  
specific poison.

If any doubt still remained on the subject, it should  
be dispelled by the fact that my friend Mr. Green, the  
experienced senior surgeon of the Bristol Royal In-  
firmary, at once recognised the disease of which his  
three patients died, as the same with the malignant pus-  
tule which he had formerly seen in Paris.

By those who refuse to admit the force of these con-  
siderations, it is no doubt possible to take another view  
of such a history. It might, for instance, be argued  
that these cases have nothing specific in them at all;

but are simply cases of pyæmia originating in some local change, however arising. And such an argument would not be altogether without support. Most practitioners must have seen at some time or other, examples of pyæmia, issuing in rapidly fatal general infection which originated in some trivial injury without the presence or intervention of any virulent agent. In such an event, personal predisposition, and what passes by the name of epidemic constitution (whatever that may mean) might one or both be supposed to play a part. The most common seat of the affection, and the comparative youth of the greater number of the subjects, might also be regarded as having each a hand in the result.

It is well known from what slight as well as various causes the lips swell to a degree that is observed in no other part, and how especially strong this tendency is in early life. In these two conditions, an explanation more or less plausible might be found of some of the peculiarities which most challenged attention in the cases before us. As a matter of fact, it is known to me that the view here put forward in this hypothetical form is the view actually entertained of these cases by more than one eminent observer, who has had many similar ones to treat. After having myself given it the fullest consideration, I am not the less convinced that it is not the true one.

This much, at any rate, is certain; that the two facts on which those who take this view chiefly rely—the seat of the affection in the face and its preference for early manhood—so far from being in their favour, must be read the other way. For these very two are among the best known of the characteristics of malignant pustule itself.

“*La face est, on peut dire, le siège de la prédilection de la pustule maligne*”—“the face is the favourite seat of malignant pustule”—says Bourgeois; a remark which is strikingly illustrated by the records of the disease, and which, I may add, is especially true of those cases in which it occurs in persons who are not by their calling exposed to direct inoculation. In pushing the analysis further, it will be found that, in the great majority of these cases, the disease was seated in the lip or in the near neighbourhood of it.

Its greater frequency in early manhood (although, as the foregoing cases show, it is by no means confined to this period of life) has not only been often remarked, but various writers have taxed their ingenuity to account for the fact.\*

To occur mostly in the face, and to attack chiefly persons who are comparatively young,† are marks which,

\* Much more precise data than any now existing would be required to show what the fact really implies. Heusinger believes that it is simply a matter of more frequent exposure. In his chapter on the influence of age, the following passage occurs:—

“In Beziehung auf der Menschen meint Erdmann, Kinder würden nicht befallen. Regnier sah den Milzbrand nicht in frühesten, und im höchsten Alter. Glaström sagt, selten litten Kinder und Greise. Ich glaube das rührt nur daher, dass sich das mittlere Alter im Allgemeinen am häufigsten der Ansteckung aussetzt, und es scheint mir eben nicht dass das Alter einen Unterschied in der Anlage begründe, denn ohne viel zu suchen bieten sich gleich Beispiele von höchsten und jüngsten Alter dar.”

That adults are much more exposed to the chances of inoculation than children is obvious enough. May not the greater frequency of the disease in adolescence than in elderly persons be due to the greater delicacy of the skin in young persons?

+ It is not a little remarkable that, except in times of great epidemics, the “charbon” scarcely ever attacks any but comparatively young cattle. “Le charbon,” says Chabert, “n’attaque guère que les jeunes animaux” (P. 151). The same observation has been made universally of the quarter evil here. Yearlings and two-year olds are, as a rule, the chief sufferers. In man and in beast alike, therefore, adolescence—if I may use such a word in common—would appear to be the period of greatest liability. The greater delicacy of the skin in young cattle may also possibly come into play here. But that would not explain why it is that young calves so generally escape. It is not impossible that, as in so many other contagious diseases, there is a certain period of life in which the specific liability is much greater than at others. As the disease is readily propagated by inoculation, it might be determined by experiment how far the greater liability of adolescent cattle depends on constitutional causes.

so far, therefore, from indicating, as some suppose, a non-specific origin, of themselves constitute a strong presumption in favour of the identity of the cases which present them with the malignant pustule. The course of the disease and the character of the morbid changes are all that remain to be taken into account, and we have already seen how perfectly and minutely identical in all the most striking of their very striking peculiarities, were the foregoing cases with the disease which is derived from the “charbon” of cattle.‡

Assuming the question of diagnosis to be settled, the next that arises is, in what way did the persons whose cases have been related become inoculated with the “charbon” virus?

Here, I regret to say, as regards the majority at least, facts altogether fail me. In the greater number, the specific nature of the disease was not recognised, and the possibility even of its having been derived from diseased cattle did not once enter the mind of the observer. With the exception of some five or six cases already specially referred to, nothing came to light to indicate in any way the origin of the disorder.

As in regard to this point I have nothing but conjecture to offer, I will be as brief as may be. In the absence of direct information, two principal modes occur to me, in which the subjects of the foregoing cases may have received this contagion. One is by eating the flesh of animals slaughtered while affected with quarter evil or blood; the other by being inoculated by insects which have previously been in contact with animals or the carcasses of animals affected with this disease. All that I know of the former mode of communication is that the material conditions for it are not wanting among us. That the flesh of oxen and sheep so affected is not an uncommon article in English markets, I have been assured by persons who have been themselves parties to the traffic. The information I have received leaves no doubt, in fact, that nearly the whole of such flesh is disposed of as food. The testimony of the many graziers and butchers I have consulted is unanimous as to this point.

In cases in which the malady is far advanced, the diseased quarter is rejected, and the other three only are sent to market. But where it is in an earlier stage, the whole carcass is often sold.

In these last I am told that a peculiar method is adopted to obliterate the marks left by the morbid change. Wherever the meat looks black or discoloured, it is dipped into boiling water, and its surface is then rapidly seared with a red hot iron. The effect of this is to cause a superficial whiteness, which in a great degree masks the mass of putrescence beneath. My authority for this statement is a grazier, who assured me that he had himself often witnessed the process.

To such a height, indeed, has immorality of this kind risen that a class of butchers has sprung up whose chief trade lies in the purchase, and sale for food, of cattle and other live stock affected with this and other diseases. In this matter of unsound meat, the inhabitants of large towns are the chief sufferers. Although too many farmers have no scruple in selling to others the flesh of diseased cattle, instinct has given them a whole-

‡ In this discussion, I have altogether left out of account the perfect resemblance of the morbid changes in these patients to those which occur in the animal; a resemblance so strikingly brought out in my friend Dr. Steele’s narrative. The early and entire death of the inoculated part, and the blackness, dryness, and insensibility of the immediately surrounding tissues in both, constitute a series of relations which is, in all ways, of very great interest. In any future cases, it might be well to put the identity of the two diseases to a still further test by inoculating some one or more of the animals subject to “charbon” with morbid products from the infected man. Virchow states that of these products the serum of the characteristic vesicles is the most virulent. In the French experiments, however, this serum always failed. On the whole, blood from the spleen appears to convey the poison the most surely. To ensure success, a young animal should be chosen, and more than one should be inoculated.

some dread of its possible effect on their own persons. But the infected carcase which cannot be disposed of to neighbours is readily sold to the unsuspecting inhabitants of the great city which lies some miles away.

The development of railways has opened new facilities for this sort of traffic, not only by offering greater secrecy for it, but by vastly enlarging, through increased rapidity of transit, the area from which such unwholesome supplies are sent.

It is well worth considering whether the increase which has certainly taken place of late years in the number of cases of malignant pustule in London and other large cities may not be in great part due to this circumstance.\*

\* These remarks were written more than three years ago. The following extract from Dr. Letehy's Quarterly Report on the health of the city of London, which appeared in the *Times* on the day following that on which this paper was read, will show how well founded they were. The confirmation of what I had suggested as to the effect of railways is especially striking:—

"The markets and slaughter-houses have been duly inspected, and the officers have seized 39,315 lbs. of meat and 765 head of game and poultry as unfit for human food. It consisted of 171 sheep, 14 calves, 43 pigs, 271 quarters of beef, and 235 joints of meat; 32,098 lbs. were diseased, 4147 lbs. were putrid, and the rest was from animals that had died from natural causes. In the course of the quarter, five persons have been convicted, at the sessions of the Central Criminal Court, for sending diseased and unwholesome meat into the city markets, and sentenced each to six months imprisonment. Their names are—Thomas Stevenson, of Millstone Lane, Leicester; John Jarvis, Towcester, Northamptonshire; Daniel Cotton, Belgrave Gate, Leicester; George Hill, Mansfield Street, Leicester; and George Warrens, Belgrave Street, Leicester. Four out of five of these persons were from Leicester, where it is to be feared the practice of sending diseased meat to the London markets is very common; and in every instance the persons were butchers, and therefore must have known the illegality of the practice."

The following extract from the next subsequent report from the same distinguished hand shows that the evil still continues. Speaking of the sanitary action of one week only, Dr. Letehy says:—

"The markets and slaughter-houses have been duly inspected, and the officers have seized 4525 lbs. of meat and 73 head of game and poultry as unfit for human food. It consisted of 16 sheep, 10 pigs, 32 quarters of beef, and about 50 joints of meat. *Three-fourths of it was from diseased animals; and I recommend that in five cases the matter be submitted to the solicitor for further investigation.* The inspectors inform me that much of the diseased meat of Newgate Market finds its way to the *sausage makers* of Cow-cross. Last week the inspectors seized the carcasses of a diseased sheep and a pig which were being carried to a sausage maker in that locality. The sheep had died from rot; and the pig was covered with small abscesses like boils, many of which had burst through the skin and the rest were still full of matter. Both of these animals were in a shockingly diseased state, and but for the interference of the inspectors would have been converted into *sauces*. I have also to state that the slaughter-houses of Cow Cross, which are just outside the city, are a source of great anxiety to the inspectors, from the circumstance that diseased animals are frequently slaughtered there, and brought into the city markets. Last week there were two such instances. Two diseased bullocks had been killed in the slaughter-house of a Mr. Crosse, and then carried to Newgate Market, where they were seized by the inspectors. In like manner, at Whitechapel, it is a common practice with some of the butchers who are outside the city boundaries to traffic in diseased meat; and the city butchers and salesmen complain that they have not the same chance for the disposal of inferior meat that their neighbours have, and that the rigorous supervision of the city is unjust to them. Only last week, the carcasses of several bullocks, about a dozen or so, that had died on shipboard, were sold in Whitechapel. Meat of this description is disposed of to the poor at night, when it passes for wholesome meat, and realises from a penny to five farthings a pound."

What is here stated in regard to *sauces* has a special importance, not only because of the obvious facilities which they offer for the disposal of unsound meat, but because, from the mode in which they are cooked, the temperature to which they are raised in being prepared for table, must often be insufficient to destroy the powers of zymotic poisons. Under these circumstances, any rudimentary entozoa that may happen to be present survive the operation; and for the same reason, I am led to believe that sausages are often the source of disease in men by the introduction of tapeworm and other parasites.

So much for the London commissariat. The following extract from the *Western Daily Press* of Oct. 3rd will show that the evil is by no means confined to the metropolis:—

"DISEASED MEAT IN BRISTOL. Yesterday at the Council House, before the sitting magistrates, Messrs. J. Poole and W. Naisb, John Cann, jun., was summoned for having in his possession and offering for sale a quantity of unwholesome meat, unfit for human food. Mr. Heaven, clerk to the Local Board of Health, appeared in support of the information, and said it was brought under the 126th clause of the Nuisances Removal Act, which prescribed a fine not exceeding £10. He further said that in the present case it was not

That every year, in most large cities, a considerable number of persons may be found who have eaten the flesh of animals affected with quarter evil or blood may be considered as all but certain.

On the other hand, I have ascertained, by careful and repeated experiments, that the temperature to which meat is generally subjected in the operations of roasting and baking, in no wise, except perhaps at the exposed surfaces, impairs the powers of animal poisons.\*

Suppose now that a person eating such infected meat roasted or baked, has a chap or abrasion on the lip, and we have at once all the material conditions that would seem to be required for an effective inoculation. Seeing how common such abrasions are, it is by no means improbable that now and then all these conditions may be found together. On the whole, however, I incline to the supposition that in the case of persons whose calling does not bring them into direct contact with the virus, the inoculation is generally effected by flies.

In two of the cases mentioned in this paper, there seemed to be direct evidence of the fact. In these two, the disease undoubtedly followed the bite of a fly and occurred in the seat of the puncture.

Great numbers of similar cases are on record,† and the fact that these insects intervene largely in the propagation of the disease is now generally admitted.‡

Some writers are even of opinion that the human subject is inoculated by them in the great majority of cases; an opinion that would go far to explain the well known greater frequency of the disease in hot and dry sum-

one bad piece that was complained of, and which might have been accidental, but several pieces, both of mutton and beef, and also of lamb; and he, therefore, should press for a severe penalty being inflicted. Mr. Yates, inspector of nuisances, said on September 20th he visited the defendant's board in the St. Nicholas Market, and there saw the whole of the fore half of a sheep in a dreadful state. It was in a basket, put a little aside, and the defendant told him it had just been left there by some one. He also saw some beef in a bad condition, covered over with a cloth. Afterwards he saw a poor woman at the board, with a piece of this beef in her hand, about to purchase it. On further looking about, he found a loin and a leg of lamb, both bad. He seized the meat; and on taking it before the magistrates on the Monday morning, they ordered it to be destroyed. Defendant said he bought the meat as being good, and owing to his defective sight, he did not know but that it was so. Mr. Yates, however, said anyone could have known it was bad by feeling it. The magistrates said they thought the case was clearly proved; and they fined the defendant 20s. and costs, or, in default of payment, one month's imprisonment. They also wished it to go forth that all cases of that sort which came before them would be punished."

It seems probable, from the account, that some of the meat here referred to was taken from animals that had died of quarter evil. It is worthy of remark that the meat would probably have been undiscovered had it not been for the increased vigilance of the police in regard to these matters, excited by the panic as to small-pox in the Wiltshire flocks.

\* These experiments will form the subject of another communication.

† The following paragraph which occurred in the *Times* on Nov. 11th, 1855, evidently relates to a case of this kind:—

"EXTRAORDINARY DEATH. Madame Moet, the celebrated proprietor of the champagne vineyards, whose daughter was married the other day, has just met with her death in a most extraordinary manner. She was gathering flowers in her garden, when she felt herself bitten by a fly. She thought nothing of the slight puncture; but in the evening her face began to swell, and a few days afterwards she died in intense agony. It is supposed that the fly must have fed upon putrid flesh."

A few months later, an exactly similar account was given in the *Times* of the death of the wife of our ambassador at Brussels.

‡ I may cite, in confirmation of this, a paragraph which appeared in the Paris correspondence of the *Times* on Sept. 26th last:—

"Cases have lately been very frequently cited in the French papers of persons becoming extremely ill, and even dying, in consequence of the stings of venomous flies, the said venomous quality being contracted by the insect from putrid substances on which it has settled. Near Soissons, a shepherd lately died in four days in consequence of one of these bites or stings. He took no heed of the first inflammatory symptoms, and when he applied to the doctor it was too late. Two other persons in the same neighbourhood were similarly attacked, the symptoms being great swelling and inflammation; but fatal results were not anticipated. Some of the French provincial newspapers have published strong recommendations to all persons who may be stung by suspicious flies or insects, to resort at once to a medical man, who alone is able to judge how far the apparently trifling injury may be serious."

mers, and in countries where insect life is active and teeming.

It would go far to explain, for instance, the much greater frequency of the malignant pustule in Burgundy than in England and the north of France, as, also, its greater frequency in Siberia and Lapland, where insects of the mosquito tribe are the great pest of the traveller.

In Lapland, indeed, before the identity of malignant pustule with the "charbon" of animals had been finally established, the popular belief was universal that the former was caused by a peculiar insect, which suddenly descended from the air and as suddenly disappeared.\*

Such consistency had this view acquired in the middle of the last century, that the illustrious Linnæus, on the strength of information received from Solander, even went so far as to admit this hypothetical creature into his systematic zoology under the significant name of "*furia infernalis*." (*Amenitates Academicæ*, vol. iii, p. 322.)

Virechow, who has made malignant pustule the subject of special investigation, and who fully admits the agency of flies in its propagation, makes the following remark:—"Most commonly insects with piercing probosces effect the inoculation, such as gadflies (bremse); but flies which make no wound, may, also, implant the poison on the skin by their soiled wings and feet." (*Handbuch der Speciellen Pathologie und Therapie*. Article, Milzbrand—Karbunkel.)

Bourgeois expresses himself to the same effect:—"The different parts of animals (he says) are not the only vehicles of the virulent principle. Certain insects, after having sucked the putrid juices of dead or sick animals, and then settled on the persons of men, may communicate the infection. I have frequently met with cases of 'charbon' in persons living near tanners and fellmongers. I have also seen, in one case, the disease caused by the puncture of a gadfly which came out of a fleece of wool."†

As the bite of those flies to which malignant pustule may be often traced is generally perfectly harmless; as these flies are endowed with no venomous powers of their own, and, finally, as the pustule to which they now and then give rise is perfectly identical with that which springs from direct inoculation, the inference seems very sure that the only part they play in the propagation of the disease is in conveying the specific virus from the infected animal to man.

That they should be frequent carriers of this virus would seem to follow necessarily from their gastronomic habits. Wherever there is a bullock or sheep, dying or dead of this contagion, especially in summer or autumn, flies of several kinds may be seen in swarms attacking the diseased part, and feasting on the stinking profluvia which often issue from the anus, mouth, and nostrils, of the diseased animal.‡

\* The following paragraph, which was published in the *Times* in the autumn of 1860, shows that this is still the popular belief in the north of Europe:—

"VENOMOUS FLIES. More than four hundred persons have lost their lives in the south of Russia, and in the province of Kiew, from the sting of a venomous fly, which has come from Asia. It made its appearance in the same country about sixty or seventy years ago."

† In the same passage, he adduces some other modes of infection which deserve mention. After relating the fact given in the text, he adds:—

"In another case, I saw it communicated by a splinter detached from a piece of wood taken from a shippen. In some cases, it is enough to touch the garments of persons belonging to the callings previously referred to (tanners, shepherds, farriers, etc.), or to hold relations with them, although they themselves may remain unharmed."

‡ In regard to this point, Hirtzmayer, in a very interesting account of a remarkable epidemic of quarter evil, which raged in the summer and autumn of 1846, among the deer of the park of Duttstein, makes, from his own observation, the following important statement:—

"Als wesentlich habe ich hier noch zu bemerken, dass die Bremzen, und zwar (a) die grosse Rind-bremse (*Tabanus bovinus*), (b) die

When the animal is flayed, they show the same fondness for the carcase, also, and (in virtue of the instinct which gives them a peculiar relish for stinking things) especially, it would appear, for that part of it which is most affected.

The only link needed to complete this chain of relations is found in the fact, of which Heusinger quotes many examples, that butchers, farriers, and others, have been bitten by flies which a moment before were seen to be so occupied, and have had malignant pustule in consequence.

I once thought that the usual situation of the pustule was almost decisive in favour of its being communicated by direct contact with tainted meat. It is certainly a very remarkable fact that in twenty of the twenty-four cases referred to in this paper, the disease began in the lip, or in the near neighbourhood of the lip: of the organ—that is to say, that seizes the food. But the fact tells, in reality, almost as much in favour of one mode as of the other. In the first place, the skin of that part being thin and delicate, is more easily pierced than other parts of the face.\* In the next place, it is, from various causes, much oftener denuded of its cuticle; and for this reason (as indeed from its greater natural tenuity, also) more open, to the accidental absorption of foreign matters. And, lastly, particles of sugar and other things attractive to flies are apt to collect about the edge of the mouth, so as to make it a favourite spot for their attack.

If it be objected to these considerations that they are too speculative, I would reply that we may, at any rate, draw this practical inference from them: not to think more lightly of a suspicious looking boil because it was known to originate in the bite of a fly.†

In considering the origin of any individual case, it is, I need scarcely add, important not to lose sight of the

Regen-bremse (*Tabanus pluvialis*), and (c) die Blind-fliege (*Tabanus coccitens*), welche im verflorbenen Sommer in unzähliger Menge vorhanden waren, wohl mit Recht als die theilweisen Träger des Contagiums anzusehen sind, und daher einere grössere Ausdehnung der Seuche verursachten. Diese setzten sich gewöhnlich zu Tausenden, auf die Cadaver der gefallenen Thiere, saugten die aus Maul, Nase, und After kommenden Profluvien ein, verliessen sodann die Leichen, begaben sich sofort auf gesunde Stücke, stachen ihren von Contagium Saurgrüssel in die Oberfläche der Haut ein, und inoculirten auf solche Weise das Seuchengift." (Kreutzer, *Central Archiv*, b. iii, p. 437.)

It will be seen that Hirtzmayer ascribes to flies the chief part in the propagation of the disease among animals also.

\* I have already referred to the part which delicacy of skin probably plays in predisposing to the disease. But, as in other contagious diseases, other and less appreciable conditions no doubt intervene. Vincenzo Malacarne, in speaking of the disease in men says:—

"Fra i quali passa gran differenza nella suscettibilità del morbo, vedendosi fra i compagni del lavoro nel macello de Buoi infetti, nella scorticatura, nelle medicature, per cui tutti sono di sangue, di sanie ugualmente aspersi, ed imbrattati, eppure certuni contraggono il carbuncchio, ed altri ne vanno esenti." (Vincenzo Malacarne, *Op. cit.*)

† This is not the only human disease in whose propagation flies play an important part. The Egyptian ophthalmia and the frambesia, or yaws (another malady indigenous to Africa), will occur to the reader as familiar illustrations. Alibert's observations on the frambesia will bear quoting in connection with this point:—

"La contagion du Tien (Frambesia, Anglécé Yaws) est à ce qu'on assure, singulièrement facilitée par une espèce de mouches que l'on nomme 'Mouches Frambesia'; et qui sont très abondantes dans les pays chauds; les mouches se reposent à tous les instans sur les horribles pustules qui proviennent de la maladie, et elles vont inoculer le virus aux individus sains, qu'elles piquent jusqu'au sang. Est-ce aussi par cette voie qu'elle a pu se transmettre aux animaux domestiques, comme on pretend l'avoir observé? L'éfleurer assure qu'il y a des endroits en Amérique, où la loi défend aux malades attaqués du Tien de sortir, et qui leur interdit même tout accès dans les hôpitaux. On trouve en effet que cette précaution a considérablement diminué la propagation de la maladie." (Alibert's *Maladies de la Peau*, p. 164.)

Curiously enough, in all these cases, the flies themselves do not seem to suffer at all from the poisons which exert such a virulent effect on the higher organisms. In helping to perpetuate these specific contagions, they perform a function which may be compared to that which Mr. Darwin, in that wonderful piece of natural history poetry, "The Fertilisation of Orchids," assigns to other winged insects in the propagation of that peculiar tribe of plants.

many other ways in which this poison may find access to our bodies. In our daily life, we come so incessantly into contact with animal products which are known vehicles of it, that it is not surprising that among the numerous persons who die of malignant pustule every year in England, the disease should often come in, like so many other contagions, through paths which it is impossible to trace.

[To be continued.]

## Progress of Medical Science.

THE DIAGNOSIS OF ECZEMA. Professor Hebra attaches a different meaning to the term eczema from that which has been generally accepted. He does not restrict the term to a disease characterised by the formation of vesicles followed by desquamation of the epidermis; but includes in it all disorders of the skin which are attended in either their earlier or their later stages by the presence of vesicles and serous discharge.

Eczema may be produced by artificial irritation of the skin. In this case, however, the results are not only vesicles and serum, but sometimes also mere redness and desquamation, sometimes small papular elevations of the size of pins' heads, sometimes even pustules and scabs. Again, there are a considerable number of cases in which the same person has on one part of his body desquamation from a reddened surface, on another red elevations as large as millet-seeds, and on another epidermic elevations filled with watery fluid; while other parts of the skin are partially denuded of their epidermis, and moistened with exudation. There may also be here and there yellow purulent points, of which some afterwards form brown or green scabs. Thirdly, the observation of the course of individual cases of eczema shows that many begin with the development of large and small vesicles, of which some become pustules, others burst, leaving exuding spots, while others are covered with yellow scabs, around which are formed papules and red desquamative spots. Towards the close of the disease, the whole of the pustules have formed scabs, which partly or entirely fall off after the drying of the exuded fluid, leaving red spots, more or less infiltrated, and covered with fine scales.

These facts Professor Hebra believes sufficient, in conjunction with clinical observation, to support the conclusion that the term eczema includes five distinct forms of disease. In support of this idea, he brings forward the following considerations.

1. The identity of the different forms of eczematous eruption may be proved by a simple experiment, which any one may make on himself or on persons at his disposal. Let an agent capable of producing artificial eczema (such as croton oil) be rubbed into corresponding parts of the skin of two persons, or into different parts of the skin of the same individual; the same quantity—say five drops—being applied to each part. In a few hours the effects will be manifested, but differently in different parts. On the scrotum and penis there will be oedematous swelling and redness, accompanied in many cases by innumerable vesicles; on the face the swelling will be more marked and the vesiculation less; while on the skin of the extremities the hair-follicles are swollen and raised above the level of the skin, and red elevations appear also here and there. If the application be not repeated, the swelling, vesicles, and red elevations disappear in a few days, leaving only slight redness and desquamation as indications of the inflammatory process that has been set up. But if the croton oil be again applied to the same parts on two, three, or more days in succession, the disease produced is increased in intensity as well as in extent. The

eruption on the parts themselves is increased, the red elevations being increased in number, and forming vesicles in consequence of the greater amount of sub-epidermic exudation; and the parts surrounding those in which the application has been made also become covered with an efflorescence similar to that which followed the application made on the first day. When artificial eczema has reached this degree of intensity, it does not end in simple desquamation; but in most cases the vesicles burst, and leave exuding spots; while the contents of other vesicles become purulent. As a consequence of the formation of the pustules, the skin surrounding them becomes more red, swollen, and painful. Having reached this point, the eruption recedes. The vesicles and pustules gradually dry and form scabs, which are thrown off by the new epidermis, leaving red patches, more or less infiltrated, and covered with desquamation.

If these results of the application of croton oil be analysed, they will be found reducible to five principal forms; viz., red elevations and vesicles, produced by the first application; red exuding patches, produced by the continued operation of the same irritation; pustules and crusts, arising from the metamorphosis of the elevations and vesicles; and finally, the red desquamating patches left after the removal of the other forms of efflorescence. These conditions are represented in several species of eczema to which authors have given names, and which Professor Hebra thus arranges in the order of their intensity: 1. Eczema squamosum or Pityriasis rubra; 2. Eczema papulosum, also called Eczema lichenoides and Lichen eczematodes; 3. Eczema vesiculosum—the Eczema solare of Willan; 4. Eczema rubrum seu madidans; 5. Eczema impetiginosum—Eczema crustosum of some authors.

Whether the same irritant will produce the same form of eczema, depends on the quantity and strength of the application, as well as on its duration. Differences arise also from the part to which the irritant is applied—the skin of the genital organs, the face, and the flexures of the joints, being most susceptible; and from the state of health of the individual, it being often impossible to produce an eruption by irritating the skin of a person in health, while, if he fall into a diseased state, an eruption is readily called forth.

2. When eczema is spread over the scalp, face, trunk, and extremities, either continuously or in patches, it rarely happens that the same form of eczema is developed on each part. For example, the scalp and the skin of the face may be the seat of impetiginous eczema, while the integument of the muscles of the ears, the nape of the neck, the axilla, and the flexures of the joints, are covered with eczema rubrum, the limbs with eczema papulosum and vesiculosum, and the trunk with eczema squamosum. It is more reasonable, Professor Hebra holds, to regard these as forms of one and the same disease, than to diagnose the eruption on the scalp as porrigo or tinea mucosa or granulata, and that on the face as porrigo larvalis, impetigo faciei rubra, crusta lactea, crusta serpiginosa, or melitagra flavescens and nigricans; while the word eczema is confined to the vesicular exudative eruption on the trunk and extremities. The terms impetigo and pityriasis rubra he regards also as having been adopted without reference to the eczematous appearances preceding the conditions which have received these designations.

3. Clinical observation affords the most satisfactory confirmation of the view here adduced. In one case, eczema begins with the eruption of vesicles; in another, the formation of vesicles is preceded by the appearance of red desquamative spots or papules. Or both papules and vesicles may be simultaneously developed; and of the latter, most rapidly form pustules, the contents of which as rapidly dry into yellow crusts. Hence it is also evident that vesicles cannot be regarded as the sole

form in which eczema at first appears. The appearance of the eczema also undergoes changes in the course of the disease. After the falling off of the crusts, the appearance known as eczema rubrum may be left; while, where vesicles have been at first developed, the outer layers of the epidermis are thrown off, leaving the rete mucosum denuded and throwing out exudation. Again, when the exudation ceases, the parts pass into the infiltrated, red, desquamating phase, known as eczema squamosum or pityriasis rubra. Professor Hebra observes, in conclusion, that this view of the metamorphosis of eczema is more probable than the idea which some have held of the conversion of one disease into another—of eczema into impetigo, porrigo, tinea, pityriasis rubra, melitagra flavescens, and the like. (*Wiener Medizin. Wochenschr.*, 27 December 1862.)

**TUBULAR PREGNANCY, FOLLOWED BY RECOVERY AND THREE SUBSEQUENT NATURAL LABOURS.** Professor Fabbri relates the case of a woman at Ravenna, who, after having had four ordinary labours, became pregnant for the fifth time. The movements of the fœtus were felt earlier than usual; the abdomen enlarged on the right side. At the ninth month, labour pains set in, and there was a serosanguinolent discharge from the uterus. These symptoms ceased in a few days; but the usual discharge after delivery and the secretion of milk continued several days longer. After this, severe symptoms set in, which confined the patient to bed, unable to move herself, for three months: they were relieved by bloodletting, aperients and clysters, and the application of emollient poultices to the abdomen. In the course of two years, the tumour, being diminished somewhat in size, became stationary. After this, she recovered sufficiently to have three successful pregnancies and deliveries. She died at the age of 55, of an acute disease, leaving directions that her body should be examined. Dr. Fabbri found at the right side of the abdomen a tumour lying behind the intestines; it was free from adhesions, but was attached to the uterus by the Fallopian tube and broad ligament. It was formed of a cyst containing a female fœtus, apparently at the ninth month. (*Bulletino delle Sc. Med. di Bologna*; and *L'Imparziale*, 1 Feb. 1863.)

**THE LOCAL AND GENERAL EFFECTS OF TAR.** Dr. J. Neumann of Vienna observes that the effects produced by tar may be divided into those arising from its application to the skin, and those resulting from the contact of air impregnated with its vapour. The effects of tar applied externally are either general or local. The general symptoms are not always present. They consist, when the application has been extensive, of fulness of the head, pain in the stomach, vomiting of dark fluid, and evacuation of dark fæces. If tar be applied to at least one-third of the surface of the body, the urine assumes a dark colour, the portion first passed being the darkest. On the addition of sulphuric acid, a strong tarry odour is developed; and the addition of chloride of iron gives a beautiful blue colour. The same appearances are observed after the use of beech-oil or *huile de cade*. It is not necessary that there should be any abrasion of the skin. The changes in the urine occur especially during the first days after the inunction of tar; while a repetition of the application produces but very slight changes in colour. Individuals also, who have been subjected to a water-bath for several days, will exhibit no change of colour in the urine, although the whole surface of the body be anointed with tar. The local changes either consist of swelling, redness, and inflammation, or in the sudden appearance of an acute eczema, which extends beyond the parts where the tar has been applied. It is impossible to know beforehand which of these conditions will be produced; and the benefits of tar in skin-diseases are so great, that the

practitioner cannot reasonably be restrained from its use by the fear that this or that effect may be produced in single individuals. The long continued inunction of tar is followed by another class of changes. Every dermatologist knows that frequently, although the skin-disease is already in course of cure, collections of pus take place under the tar, and raise it when adherent. The effects of vapour of tar were observed by Dr. Neumann in a patient who was affected in a similar manner to fifty-nine others in a spinning-factory. The face was covered with numerous pimples: there were also spots of acne, and pustules; the conjunctiva of the bulb was injected on both sides. The chest and back were free; the lower extremities presented eruptions similar to those in the face—some of the pustules being as large as hazel-nuts. It was found that, since the wheels of the instruments were smeared with tar instead of fat, this diseased condition had appeared; and that it ceased when fat was again used. Dr. Neumann has subsequently seen three other cases in which acne was produced by air impregnated with tar-vapour. He does not think that the effect is produced by inhalation; because the parts most closely covered by the clothes remain free. (*Wiener Med. Wochenschr.*, Dec. 20, 1862.)

**ERYSIPELAS OF THE FACE IN INTERMITTENT FEVER.** M. Desguin states that he observed, in the end of September and beginning of October 1861, a large number of cases of erysipelas of the face complicating intermittent fever. In every instance there was well marked gastro-intestinal disorder—white furred tongue, constipation, severe headache, more or less intense febrile reaction, etc. In some cases, the patients had the erysipelas at their entrance into hospital; it was here consecutive on the appearance of the fever, and accompanied it. In another class of cases, the erysipelas appeared only some days after the patients were admitted; sometimes it was moderate, but often very severe. It appeared to be simple; but, in two or three days, well marked paroxysms of fever appeared. As in the other cases, the two diseases ran a concurrent course, presenting the same periods of aggravation and remission. By the use of purgatives, followed by sulphate of quinine, both the intermittent fever and the erysipelas were removed. If the erysipelas were at first apparently unaccompanied by intermittent fever, and were treated alone, the paroxysms of fever soon appeared, and the use of quinine became unavoidably necessary. (*Arch. Belges de la Méd. Militaire*; and *Gazette Méd. de Paris*, Nov. 1862.)

**FORMATION OF IMAGES IN THE EYE.** M. Vulpian, at the end of a memoir on "monocular polyopia", states that the study of this subject leads to the following conclusion, which has also been expressed in very explicit terms in a work by M. Trouessart. The eye is so constituted, that the rays of light which penetrate it form several pencils, and thus tend to produce several images of the object from which they emanate. If the object be placed within or beyond the distance of distinct vision, the pencils are more or less separated when they reach the retina, and several images are formed on that membrane—there is, in a word, polyopia; but if, whether naturally or by the use of concave or convex glasses, it be at the distance proper for distinct vision, the pencils converge, the images are united into one on the retinal focus, and the object is seen simple. (*Gaz. Méd. de Paris*, 20 Decembre 1862.)

**STRANGURY FROM CANTHARIDES.** As a remedy for strangury arising from the use of cantharides, Dr. Ameuille recommends the liquor potassæ of the English *Pharmacopœia*, in twenty-minim doses. He says that its use is immediately followed by marked improvement in the symptoms. Generally in about half an hour

after the second dose, and always after the third, the symptoms are completely relieved. (*Union Méd.*; and *Bulletin Génér. de Thér.*, 30 Nov. 1862.)

## Reviews and Notices.

**A TREATISE ON GALL-STONES: THEIR CHEMISTRY, PATHOLOGY, AND TREATMENT.** By J. L. W. THUDICHUM, M.D., Member of the Royal College of Physicians. Illustrated with Plates. Pp. 323. London: 1863.

THE pages of this JOURNAL, as well as of contemporary medical and scientific periodicals, have within the last few years from time to time contained accounts of the results arrived at by Dr. THUDICHUM, from his investigations into the nature and mode of origin of gall-stones. These results, with a quantity of other matter derived from literary research and from work in the laboratory, he has put together and arranged in the volume before us.

The book consists of six chapters. In the first, the author gives a Digest of the Historical Literature of Gall-Stones; referring to all who have described or written on them from Alexander Trallianus down to Frerichs. This chapter is apparently most complete, and must have cost the author much searching among old books; notwithstanding the assistance which he acknowledges in his preface to have received from Mr. Chatto, the courteous librarian of the College of Surgeons.

Having disposed of the literary portion of the work, the author turns to the scientific and practical aspect of the subject, and treats in the remaining five chapters of the Physical Description of Gall-stones; their Chemistry; the Origin and Theory of Gall-stones; the Anatomy of Gall-stone Disease; and its Pathology and Treatment.

The chapter on the Chemistry of Gall-stones is, as would be expected from Dr. Thudichum's well known chemical skill, very full. The author first gives an outline of the attempts which have been made from time to time to determine the composition of these bodies, and then describes the process which he has followed in their analysis. Next, he offers some general considerations on the ingredients existing or said to have been found in gall-stones, whether constant or accidental; speaking in order of cholesterine, cholochrome, the biliary acids, their derivatives and salts, fatty acids and their salts, uric acid, a new organic substance, epithelium, mucus and albumen, water, mineral acids, earths and alkalies, and metals and their oxides. He then gives a classification of gall-stones, arranging them in the following seven series.

- "1. Pellucid or pure cholesterine calculi.
- "2. Mixed calculi, with prevalence of cholesterine.
- "3. Calculi with prevalence of cholochrome.
- "4. Calculi with prevalence of modified cholochrome.
- "5. Gall-stones with prevalence of bile-acids.
- "6. Gall-stones with prevalence of fatty acids.
- "7. Gall-stones with prevalence of carbonate of lime."

He then notices the occurrence of gall-stones in the various classes of vertebrate animals, and describes at some length the chemical processes to which he has subjected gall-stones derived from the ox.

Before proceeding to notice Dr. Thudichum's theory of the origin of biliary calculi, it will be well to explain what he means by the term *cholochrome*.

"The word *cholochrome* is intended to designate colouring matter of bile and all its varieties. For the brown colouring matter I retain the name *cholophæine*; for the green variety I adopt the name *cholochloine*. The older names of cholepyrrhine, biliphæine, and bilifulvine, may be considered as synonymous with cholophæine. Biliverdine and cholechlorine are synonyms of cholochloine.

"Cholophæine seems to be a mixed form of colouring matter secreted by the liver. It occurs in gall-stones in a free state and in combination. In its free state it makes up the greater part of the bulk of ox gall-stones; it is deposited in casts of the biliary ducts found in the centre of human gall-stones, and also occurs in the nuclei and layers of these latter in an amorphous state; a certain part of it contained in gall-stones is always combined with lime or with carbonate of lime. Cholochloine, in combination with bases, is present in the darker variety of human gall-stones, giving them a green and sometimes an almost black colour. In the free state it is soluble in alcohol, and may be isolated thereby." (Pp. 90-91.)

In the chapter on the Origin and Theory of Gall-stones, Dr. Thudichum commences by comparing briefly the composition of human gall-stones with the concretions from the ox. In gall-stones from man, there is a small amount of free biliary acids, cholochrome (combined with earths when in moderate quantity); and a large amount of cholesterine in most cases. In ox gall-stones, the quantity of biliary acids (cholic and choloidic) is large, a small proportion being combined with lime; the cholochrome is mostly free; and there is no cholesterine. Hence, by a process of elimination, and retaining only the common factors of the gall-stones of man and of animals, Dr. Thudichum observes that

"Cholochrome, cholic and choloidic acids, and earthy salts, thus present themselves as substances without the concurrence of which the more common forms of gall-stones would rarely be formed; they are, in other words, essential ingredients of gall-stones." (P. 166.)

Cholesterine, which forms so large a proportion of human gall-stones, is, then, only a secondary ingredient. It is absent altogether in the biliary concretions of the ox, and sometimes in those of man; while occasionally the latter consist almost entirely of cholesterine.

The ordinary process of the formation of gall-stones is believed by Dr. Thudichum to be analogous to that which produces phosphatic or fusible calculi in the urinary passages.

"It is a decomposition of the bile, akin to putrefaction. The compound amido-acids" (taurocholic and glycocholic, which exist in combination with soda) "split up into their constituents" (taurine, glycoceoll, and cholic acid combined with soda), "under the influence of a cause which remains to be ascertained, but is probably a putrid ferment absorbed from the intestinal canal. Under the influence of a little acetic acid, formed out of glycoceoll and some other new acid produced by the putrefactive change, perhaps valerianic acid, cholochrome, a quantity of cholic acid, and a portion of choloidic acid, together with some salts and a little fat, are deposited. This is the process in the ox, and sometimes in man. But the bile of man differs in this respect from that of the ox, that it contains cholesterine, while that of the ox contains, at the most, only a small quantity as compared to the other. This cholesterine is dissolved in the tau-

rocholate of soda. But, as soon as the acid of this salt is decomposed, the cholesterine is set free, crystallises, and deposits upon any particle that may happen to be within easy distance, in the manner of all crystals, which like to post themselves upon prominent bodies." (P. 167.)

These remarks are followed by an account of the results of investigating the products of the decomposition of bile, kept in well-stoppered bottles for one and two years. This examination was undertaken with great care by Gorup-Besanez, an account of whose experiments and conclusions Dr. Thudichum gives, at the same time stating certain points in which he had been led to differ therefrom after a similar series of investigations. The following diagram is given by Dr. Thudichum as illustrating generally the stages through which bile passes in the course of decomposition; although he does not assert it to be "an absolute syllabus of a variable process."

"First Stage. The bile is neutral or alkaline.

"Taurocholate of soda yields cholate of soda and taurine.

"Glycocholate of soda yields cholate of soda and glycochol."

"Margarate (palmitate) and stearate of lime, and phosphate of lime and magnesia, are deposited.

"Second Stage. The bile becomes acid by the super-vention of a new (valerianic?) acid, whose origin is undecided.

"Cholate of soda deposits cholic acid.

"Soda salt of new acid is formed.

"Cholochrome is precipitated; a part only remains dissolved, giving to the fluid a crimson colour.

"Glycochol yields acetic acid and ammonia.

"Third Stage. The bile contains acid.

"Cholate of soda is transformed into choloidate. The latter deposits some choloidic acid (?).

"Choloidate of soda yields fatty acids, products of decomposition; among them, probably derived from glycochol, is found acetic acid." (P. 171.)

Thus we have, as the result of the decomposition of bile, a deposit of the same nature as that which Dr. Thudichum finds to be essential to gall-stones; viz., stearate and palmitate of lime, cholic and choloidic acids, cholochrome, phosphate of lime, and mucus.

Having disposed of his chemical investigations, Dr. Thudichum describes *seriatim* the different positions in which gall-stones are found, their real or supposed causes, the symptoms produced by them, the modes in which they escape, and the diagnosis of gall-stone disease.

He then proceeds to notice the treatment. To relieve the symptoms produced by the passage of gall-stones—during the occurrence of which medical aid is generally called in—he has found a combination of anæsthetics with anodynes the most useful remedy. Regarding anodynes, he offers some cautions which should be borne in mind. The pain is sometimes so great as to be scarcely affected by large doses even of such remedies as tincture of opium or solution of morphia; but, if the pain (whether from the action of the remedies used, or spontaneously) suddenly cease, the symptoms of opium-poisoning occur, and may become highly dangerous. In illustration of this point, Dr. Thudichum refers to the case of a member of Parliament (the late Mr. A. Stafford), which caused considerable stir in the profession a few years ago.

The treatment which Dr. Thudichum follows for the relief of the colic caused by the passing of gall-stones is thus described by him.

"It is, under all circumstances, advisable that the practitioner, when once at the bedside of a patient with severe colic, should remain there, and administer the medicines himself, until some relief has been obtained. He may administer twenty minims of chloroform upon a piece of sugar, to be washed down with the necessary quantity of water. This may be repeated every twenty minutes, until a drachm has been used. If the patient is inclined to be sick, the taste and salivation excited by the chloroform are apt to cause an increase of the sickness, or to produce vomiting. This should be foreseen, and slightly alluded to as possible in the conversation with the patient. It is not to be regretted, but necessitates the application of the remedy by inhalation, or its entire abandonment. Along with the chloroform a solution of morphia may be given; one-eighth of a grain every half-hour, or, according to circumstances, at longer intervals, until half a grain—in strong and hale persons up to a grain has been given—is a proper dose. Laudanum must be given more empirically in doses of from five to ten minims at proper intervals, largely diluted with water, as its effects vary more than those of the solution of morphia.

"The anodyne effect of the chloroform can also be obtained by sulphuric ether, which, like chloroform, may be used mixed with equal parts, by measure, of the strongest spirit of wine. This anodyne liquor of Hoffmann is also best taken upon sugar, in small, often-repeated doses. It is not so apt to favour vomiting as chloroform, and in cases of lowness of the vital powers has a most satisfactory collateral effect upon the pulse, and the powers of the voluntary muscles." (Pp. 278-9.)

After the relief of the pain, purgative medicines and enemata, emetics, the application of warmth to the painful region, warm water-baths, moderately stimulating drinks, sundry mineral waters, etc., are to be used under conditions for an account of which we must refer the reader to the book itself. Dr. Thudichum does not seem to have much faith in the theory of Frerichs, that very alkaline bile can break up gall-stones by dissolving out their connective material; but he admits that there is still room for therapeutical experiments in this direction, especially by the administration of phosphate of soda.

We have read Dr. Thudichum's book with pleasure and profit. He has not, it is true, succeeded in bringing science and practice into complete harmony in the matter of the treatment of gall-stones; but in constructing as a chemist a theory of the formation of these bodies which bears a strong aspect of probability, and in furnishing at the same time the results of his observations as a practical physician, he has made a valuable contribution to scientific medicine.

A MANUAL OF ELEMENTARY CHEMISTRY, THEORETICAL AND PRACTICAL. By GEORGE FOWNES, F.R.S., late Professor of Practical Chemistry in University College, London. Ninth Edition, revised and corrected. Pp. 820. London: 1863.

THERE is not one volume in Mr. Churchill's excellent series of manuals, which has gone through so many editions in so short a space of time as the *Manual of Chemistry*. Its able editors, Drs. Bence Jones and Hofmann, have, in each issue which has appeared under their auspices, incorporated the additions made to our chemical knowledge; and hence,

in the present edition, the reader will find an outline of the two last great discoveries in chemical philosophy—the spectrum analysis, and Mr. Graham's researches on dialysis or diffusion analysis. Certain additions have also been made in organic chemistry; and in animal chemistry we have a notice of some remarkable experiment of Pettenkofer on respiration.

The part of the work which treats of Animal Chemistry does not appear to us to be equal in merit to the other parts of the book. The editors make little or no reference to the investigations made by Englishmen in this department; at all events, we miss any allusion to the researches of Edward Smith on respiration, of Richardson on the function and evolution of ammonia, etc. Should not the animal chemistry department be more expanded—perhaps into a separate manual? Our knowledge of the subject, both physiologically and pathologically, has grown so immensely, that it cannot well be compressed within less than fifty pages at the end of a general treatise on chemistry.

Having administered a little blame, we must not omit, in conclusion, to say that the praise due to the editors is much greater. No one expects so much in a manual as in larger treatises; but in the parts which treat of Physics, of the Chemistry of Elementary Bodies, and of Organic Chemistry, Drs. Bence Jones and Hofmann have left little or nothing to be wished for.

## British Medical Journal.

SATURDAY, MARCH 7TH, 1863.

### UNLICENSED PHYSIC.

COMPLAINTS are frequently made against the Medical Council and the Medical Act, that they do not, or are powerless to, put down unlicensed practitioners of medicine. Now, we may perhaps venture to doubt whether the Medical Council has used all the powers invested in it for this and for other purposes. We may fairly say, indeed, that the Council likes its ease too well to dabble in the muddy field of discord and litigation; and that it has not yet put itself in a position of saying: "We have done all that we possibly can to purge the profession of illegitimate practitioners—all that the law allows us; and can, therefore, do no more." There is too great a leaven of conservatism and quietism in the Council to expect any great energy to be exerted in its proceedings in this direction or any other. To fight against the iniquities which hang about the medical profession is what we can never expect such a body to do. Combats of such a nature indicate struggles and violent efforts, and energies to be exerted, and base things to be overcome. But it is only fair to add, that we fear no efforts on the part of the Medical or any other Council would avail to put down irregular

practitioners and quacks, notorious or obscure. Free trade is the motto of this country; and the public will have free trade in physic, as well as in corn and cotton, or any other dry or moist goods. The habits and manners of the English Saxon are such, that it is impossible to prevent any British lion or lioness from placing their faith and their bodies in the hands of the most villanous quackeries and quacks. Any pretender in this country may physic or set the broken bones of any one who is idiot enough to subject himself to the pretender's tender mercies. The pretender, it is true, is amenable to the law if he makes a mistake, but only just as the regular practitioner is; the only difference being, that judge and jury invariably favour the brutalities of the quack when he falls into their hands, and severely punish the errors of the doctor. The enormous amount of rampant quackery in this country, the thriving tribe of those who practise it, show how dearly we cling to our freedom of opinion. And besides this, as we well know, there is no class of men who more deeply indulge in this vein of quackery than the class who legislate for us. It is, therefore, impossible to hope that the legislature will ever assist the profession in attempting by any summary process to put down irregulars.

But, again, if we cast our eyes across the Channel, we shall not find in France much to encourage us in hoping by legal enactments to stay quackeries. In France, no man nor woman is permitted by law to practise medicine, unless regularly authorised by diploma. Yet, do we find the law efficacious in this respect? Nothing of the kind. Bone-setters, urinedoctors, wise men and women, diviners, *les religieuses*, and all the infinite tribe, *ambubiarum collegia*, are as thickly strewn through France as they are through England. Spite of the law against irregular practisers, even in Imperial France the people, from the highest to the lowest of them, will have their pet quacks and quackeries. They have their Docteur Noir, curer of cancers, just as we have our friend of puccoon fame, curer of cancers. Eugenie has her nerves soothed or excited by the spiritualist and table-rapper, just as freely as we have our fashionables' nervous systems enlightened by Mesmerico-kineopathists, etc. In a word, we cannot for a moment doubt that quackery has just as fine a field to sport over in France as it has in England. And what does the law in France do, or can it do, to stop the thing? There is there, as our readers know, a Medical Association, of late and yet of very vigorous growth; and, amongst other things, this Association has of late taken in hand the attempted suppression of quacks. In the French medical journals, consequently, for some few years past, we continually read of the processes made and carried against le sieur Casse-Os, or against la dame Noire, as being irregular practisers of medicine and sur-

gery. We read a long *procès-verbal* and a long judgment, which always end in a fine of five *francs* and damages. Nay, we often read that this is the third or fourth time that the bone-setter or the wise woman has been brought before the tribunals; and that, so far from arresting their progress, the notoriety obtained by previous prosecutions and convictions has enormously increased their practice; and that they, therefore, pay their fines with pleasure, and are thankful to their prosecutors for advertisement and increase of fame and practice. More than this, we lately read in a French journal that M. le juge, before whom one of these irregulars—these Bashi-Bashouchs of society—was brought and fined his petty fine, was actually, at the time of his giving judgment, under the hands and treatment of the quack whom in his legal capacity he had fined. It is, therefore, felt that these prosecutions in France are failures; and, indeed, several of the journals there have given it as their opinion, that the profession is acting a very undignified part in constantly making itself the prosecutor (or, as the public regard it, the persecutor) in such cases, more especially as its efforts to keep down the hydra are so manifestly abortive.

If, then, in beaurocratic and well-*préfi* France, with the law to aid, attempts to suppress irregular practisers fail, can we hope that they will ever succeed in England? We fear not; and we therefore cannot look with any hope for aid in this direction to the Medical Council. We must be contented in this matter to rest upon our character as a professional and learned body; and we need not fear that we shall ever lose the confidence of the public at large. In the meantime, one thing we may do; and that is, suppress all quackery within the profession itself—the most dangerous of all the enemies which we have to encounter in this line—the quackery of homœopathy; the quackery of advertisement, whether by newspapers or public appointments; the quackery of pretending to cure whilst we only administer to nature; the quackery of competition; the quackery of gratuitous charitable medical services. The suppression of these, and of a dozen such abnormities which we could mention, will, we suspect, do more to elevate our profession, and to put down outside irregularities, than any Act of Parliament will ever do for us.

#### THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE Annual Meeting of the Medical and Chirurgical Society was held at the Society's rooms, on the 2nd inst., when the following gentlemen were elected officers for the ensuing year:—*President*—Mr. R. Partridge; *Vice-Presidents*—Dr. Hodgkin, Dr. West, Mr. John Hilton, Mr. William Fergusson; *Treasurers*—Dr. Pitman and Mr. James Dixon; *Secretaries*—Dr. Sieveking and Mr. John Birkett; *Librarians*—Dr. A. Stewart and Mr. Henry Lee; *Other Members of Council*—Dr. Cotton, Dr. Gream, Dr. George Johnson, Dr. Markham, Dr. Sibson, Mr. G. V. Ellis, Mr. Holt, Mr. Holthouse, Mr. E. Newton, Mr. Toynbee.

The Report showed that the Society was in all respects in a most flourishing condition—rich in members, and rich in wealth. We need hardly add, that the late efforts of the Society to advance the science of medicine have also made it rich in reputation. Last year, a Committee investigated the subject of Suspended Animation; and this year another Committee, composed of gentlemen of the highest scientific acquirements and of great practical knowledge, has been appointed to inquire thoroughly into the History of Chloroform, its best mode of administration, its therapeutical and its toxic actions, its right uses, etc. It may be safely asserted that the Society was never in a higher state of efficiency and power than it is at the present moment.

The retiring President (Dr. Babington) delivered a very eloquent address, which will appear in the *Proceedings* of the Society, and which received the warmest approbation of the members present. In the conclusion of his address, the President made some excellent remarks, or rather gave very judicious advice, to gentleman who take part in the Society's discussions. He thought, and most of us will agree with him, that a word of rebuke was required to check the inclination, too often observed of late in the discussions, of indulging in *tu quoque* sort of rejoinders, for we cannot call them arguments. In a scientific society, personalities and acrimonious language are things to be especially eschewed. They manifestly cannot forward the objects of science; and they certainly do not exalt our profession either in its own eyes or in the estimation of the public. We would especially call attention to these remarks of the President, who so wisely protested against sensation subjects of discussion and sensation speeches.

The question of enlarging the Society's rooms also came before the meeting; but the Society did not see its way to take any steps in this oft debated matter. This much, however, appears certain: the rooms are not worthy of the Society, and are quite unequal to the accommodation of the splendid collection of books which is daily and rapidly increasing within its walls. But the difficulty to be met is a financial one. A very large sum of money would be required to enlarge the rooms; and it does not appear certain, even if the rooms were enlarged as proposed, that the Society would possess a fitting habitation. This is just one of those cases which is sometimes happily provided for by a wealthy and benevolent individual, who would in this case earn

the lasting gratitude of his professional brethren, and hand his name honoured down to posterity, by making provision for the erection of a dwelling worthy of the first medical society of the country. Surely there is nothing chimerical in the hope that such a luck may one day fall upon this Society.

### THE INDIAN ARMY MEDICAL SERVICE.

We think it right to give a prominent position in our pages to the following remarks on the condition of the Indian army medical officers. It is from the pen of a gentleman who knows well the subject on which he writes. The thanks of the profession are due to him for his clear exposition of the present position of the Indian army medical officers, and of the shameful and cruel treatment to which they have been subjected by authority. The lines are headed, *A Few Words of Warning to the Medical Students of Great Britain.*

"Among the large body of medical students now qualifying themselves in the various schools of the United Kingdom for the practice of their profession, there are members who look forward with confidence to a future career of honour and emolument in the army medical service. The British Government, on the other hand, expects with equal confidence, that the needs of the public service will continue to be supplied, as they have hitherto been, by a never-failing tide of skill, energy, and devotion. But each party may find itself mistaken, when the rising generation of medical students learn, as they may, that military medical officers, so far from being honoured and cherished by the Government, are treated as of light estimation; that their rights and privileges, acknowledged and granted by the Crown, and guaranteed by Act of Parliament, may be set aside and held in abeyance; while false hopes of benefits to come, ever seeming near at hand, and ever fading away in the distance, are held out to them, to cover broken faith and cold indifference.

"Medical students of Great Britain, listen to the voice of one who now speaks to you from India, in the hope that you will, as you can, unite to obtain justice and fair treatment for your professional brethren now—for yourselves hereafter; justice and fair treatment, which are denied to the officers of the Indian medical service to-day, and which may be refused to yourselves at a future time. The Indian medical service, it is true, is closed, and you may think that better treatment awaits you in that of the royal army; but pause and reflect, ere you put faith in a Government, which, wishing to be rid of a service that has ever done its duty nobly, can cast it away with ingratitude and contempt; which can raise hopes only to disappoint them; scatter to the winds privileges secured by Act of Parliament; nullify and make void a royal warrant.

"That such has been the action of the Government towards its medical officers in India, let the following statement prove.

"In the year 1858, when the government of India passed from the hands of the Hon. East India Company into those of the Crown, there existed in India two distinct medical services, the Queen's and the Company's. Each had its own privileges and advantages, and was in all things independent of the other. The latter service, with the military and naval forces of the Company, was then transferred to the Crown; the pay, pensions, and privileges as regards promotion and other-

wise, which they had enjoyed in the service of the Company, being guaranteed to them by Act of Parliament (21 and 22 Vic., cap. 106).

"It was determined to amalgamate the two medical services, and to make them equal in pay, promotion, and pension; but various difficulties were found to stand in the way; and, as a temporary measure, a royal warrant was issued bearing date February 1st, 1859, which was supposed to confer upon the Indian medical officers certain advantages, which had, in the preceding year, been conceded in like manner to the royal service.

"This warrant, by some of its provisions, altered existing rules with regard to promotion in the Indian medical service, and might, therefore, be regarded as an infringement of the covenant under which the Indian officers enlisted, and a breach of their privileges guaranteed by Act of Parliament. Professing to place both services on the same footing, it in reality gave an inferior position to the Indian, and it was, in consequence, regarded as not entirely satisfactory. Nevertheless, it was accepted as an omen of promise, an evidence of goodwill, an earnest of better things to come. Time only was wanting to show that the royal warrant was but 'a mockery, a delusion, and a snare.' Four years have passed away since it was penned, and it remains an empty unfulfilled promise.

"Nominally, indeed, the warrant is in force; its titles are conferred, but the rank, precedence, and pay, which they should carry, are all withheld.

"Surgeons, after twenty years service, are appointed surgeons-major, and should, according to the original warrant, hold the rank of lieutenant-colonel, but junior of that rank. Regimental surgeons should rank with majors according to the dates of their commissions. Such relative rank should, in the words of the warrant, 'carry with it all precedence and advantages attaching to the rank with which it corresponds,' and should 'regulate the choice of quarters, for age, and prize money.' Actually, however, it carries none of these advantages.

"The surgeons-major are not even recognised as a separate class in the official Army List. A reissue of the warrant by the Horse Guards decrees that the surgeons shall rank as majors, *but junior of that rank*; precedence is refused to them; it has been ruled that they hold only brevet rank, and they are allowed to draw only captain's pay.

"Thus is the shadow only given where solid advantage has been promised; but the substance is freely conferred when the provisions of the warrant are injurious to those for whose benefit it was designed. Henceforth, in the words of the warrant, 'No assistant-surgeon shall be eligible for promotion to the rank of surgeon, until he shall have passed such examination as our principal Secretary of State for India in Council may require, and shall have served in India with the commission of assistant-surgeon for five years, of which two shall have been passed in or with a regiment.' And 'a surgeon, whether on the staff or attached to regiments, must have served ten years in India, of which two must have been passed, with the rank of surgeon, in or with a regiment, before he will be eligible for promotion to the rank of deputy inspector-general of hospitals.'

"These rules, applied, as they are to be, to officers who entered the service prior to the date of the warrant, are breaches of faith; alterations of existing rules for promotion, the continuance of which had been guaranteed by Act of Parliament, as above stated.

"Every assistant-surgeon who enlisted prior to the date of the warrant, entered a seniority service, and understood that promotion would be his when he arrived at the head of the list, without reference to the nature of his past employment; and he has as just a right to promotion by seniority as he will have to pension on the completion of his service.

"Under the new rule, assistant-surgeons who have been transferred to the civil department before completing two years of military service, who have held charges of the most responsible nature, and have enjoyed the advantages of a far wider field of practice than is generally offered by a regimental hospital, must resign their appointments and seek military service, or indefinitely forfeit their promotion. Pecuniary loss and great personal inconvenience will thus be the reward of years of useful service; and every officer who comes under this regulation, will have reason to complain that faith has not been kept with him, and that he has been subjected to what in former years would have been considered as the punishment of a fault. Recently, as if in mockery of the wrongs under which these officers smart, the option of resigning their appointments has been offered them. They have been invited, 'should they desire it,' to arrange for fulfilling the period of army service required; to reduce themselves, probably, from positions just fairly remunerative and no more, to the smallest military allowances while doing duty with a regiment, to the ruin of themselves and their families. Hereafter, when the promotion, which should be theirs by good service and by right, is denied, they will be told, 'It is your own fault, you were duly warned.'

"The rule which requires two years military service as full surgeon as a necessary qualification for the rank of deputy inspector-general of hospitals is equally objectionable. Among the surgeons of the Indian medical service are many who have spent their whole time in civil employ. After having given their best energies to the service of government for years, after having held appointments entailing the most onerous professional duties, these officers are to be considered unfit for the rank of deputy inspector-general of hospitals unless they forfeit their appointments and perform the required amount of regimental duty. A similar rule to this, indeed, formerly existed in the Indian medical service, but, owing to its injurious action, it was wisely repealed. Such regulations, while they effect no public good, serve only to irritate and annoy individuals, to raise a general feeling of discontent, and to make every officer feel that he belongs to a service which the Government delights to dishonour.

"The examination of assistant-surgeons to ascertain their fitness for promotion, has not yet been brought into practice. It cannot be enforced in the case of officers who entered the service prior to the date of the warrant without interfering with their privileges guaranteed by Act of Parliament. In any case it would be as absurd as it is insulting to the profession at large. The proposal to examine men, whose fitness has been proved at the commencement of their career by proper authority, and subsequently, by years of successful practice and unchallenged good repute, is preposterous. The universities and examining boards are in duty bound to protest against such treatment of their graduates. Assistant-surgeons should unanimously refuse promotion offered to them on terms so derogatory to the honour of their profession; and properly qualified medical men should decline to enter a service which threatens them with so degrading a condition.

"While some portions of the warrant have been dealt with in the manner before described, others have been kept entirely in abeyance; but it is not necessary to take notice of these: enough has been said to shew, that the original warrant, designed in a spirit of liberality has been so tampered with, that it tells against, rather than in favour of, those who expected to receive in it a boon. The officers of the Indian medical service asking for bread, have received a stone; they have trusted to a broken reed and it has pierced them. There are at least four years arrears of the pay of their rank promised in the warrant due to them, and they may justly complain that they have been treated with injustice and contempt,

and that they have purchased their commissions at the cost of their birthrights as Englishmen.

"Lastly, during the four years which have elapsed since the warrant was signed, what has been the conduct of the government towards the service? Well knowing the anxiety felt by the Indian medical officers, has it vouchsafed them one word of explanation and encouragement? In all its futile deliberations concerning the amalgamation of the services, has it called to its councils any of those most interested? The answer must be 'No.' Military officers have been employed to draw up schemes for the amalgamation, and to officiate as amateur actuaries in winding up the affairs of the Medical Retiring Fund. That fund, a private association for the grant of annuities to retiring officers, to which subscription was made compulsory by government, is now dying of inanition. The closure of the Indian medical service has nipped its roots; no new subscribers are added to its list, while its expenditure in annuities increases yearly. It is said, indeed, that the government guarantees the advantages of the fund to the present subscribers, but of what value is a government guarantee to men with whom government has already broken faith?

"It is unfortunately a fact too well established to be doubted, that medical officers of all branches of the service have ever been hardly treated by the Government; and that what consideration they now enjoy has been granted to them only by degrees and under pressure. But a few years ago, the position of the medical officers of the navy was so degraded, that no candidates could be found for employment in that service. The students unanimously refused to enter the navy; and at length the Secretary of the Admiralty reported that no surgeons were forthcoming to fill the vacancies. Then, and not till then, were naval medical officers treated as gentlemen and members of a learned profession.\*

"Such a crisis is now at hand; a paucity of medical officers is becoming felt in India; many of the seniors, disgusted with the treatment they have received, are anxious to retire;—let their want and their worth be felt. Now is the time for the students of medicine to assist their elder brethren, and to secure their own future prospects. Let there be a cry for military surgeons, and no response; then, and then only, will military surgeons receive the treatment which is their due. Let vacancies in the army medical service remain unfilled until an order of Government is published and communicated to the schools, promising that the original warrant, prepared in a true spirit of liberality by the late lamented Sidney Herbert, shall be strictly and faithfully observed; that the rights and privileges of the medical officers in India shall be respected; and that they shall receive, in accordance with the terms of the warrant, their proper pay and staff allowances, and *bonâ fide*, not brevet rank.

"Let it ever be remembered, that the rank and position of the army medical officer must be established on the firm and permanent basis of the Royal command; not on a sand so shifting and treacherous as the favour and good will of any subordinate authority.

"So long as a Royal warrant may be altered at the pleasure of a Secretary of State, so long will it be unworthy of the name; so long will the position of the medical officer be uncertain and unsatisfactory, and dependent only on the urgency with which his services are required. So long, in fact, will it be undesirable to become

"AN ARMY MEDICAL OFFICER."

\* The Naval Medical Warrant, however, has been indirectly tampered with, and is susceptible of amendment. The rank of the executive officers relatively with the army has been raised so as to keep the medical officer below. A lieutenant of eight years standing in the navy now ranks with a major in the army, and so obtains precedence of a medical officer of the same standing.

## THE WEEK.

DR. PHILBRICK has, we are informed, yielded to the pressure of circumstances, and settled the action which has been brought against him. Our readers are aware of the history of this case. Never, in our opinion, was a more unjust action brought than this against Dr. Philbrick, and thanks to his professional brethren. That Dr. Philbrick has not been able to face the uncertainty of the results of a trial, and the anxiety attending it, we must sincerely regret for the sake of truth and justice; but we cannot blame him after what we have recently witnessed of the vagaries of a jury in a court of law. One question, however, there is of a scientific interest, which has been brought forward through this action, and it is well worthy of the attention of the profession; viz., what is the right and proper practice to be pursued in the case of twins, when the second child is retained beyond the ordinary period after the delivery of the first? Ought the accoucheur to interfere, no urgent symptoms pressing; or ought he to leave nature to accomplish the second delivery. It would appear that authorities have laid down no distinct line of practice; and that those who recommend interference when a certain time has elapsed after the delivery of the first child have not shown good grounds for the interference. We have received some communications on the subject; and as it is one of practical interest, perhaps those of our profession who have had large experience in midwifery will give us the benefit of their opinion upon it. What are the rules which should guide the practitioner in dealing with a case of twins, when the second child is retained beyond the ordinary period?

It is well that members of the Medical and Surgical Society should know that the ordinary meeting of the Society, which should take place on the 10th inst., will be allowed to lapse away quietly. That day is, as we need hardly say, a day of national excitement; and few members of the Society will be calm enough to settle down in the evening of it to a quiet discussion of topics medical. The meeting must, nominally at least, according to the laws, be held; but, of course, the members need not attend, and so it will fall through.

THE Manchester Medico-Ethical Society held its annual meeting on January 27th last. We are glad to find so useful a society still flourishing. Its report tells of the activity of the members and of its earnest desire to promote the honourable standing of the profession and to watch over its interests. Its work may be judged of from the following extract of the report:—

“Misunderstandings and mutual jealousies are extensively rectified; medical coteries are usefully invaded,

and their exclusiveness mitigated, by the assembling, not less than four times a year, of members of the profession of all grades and professional standing, at a repast worthy of the profession and of the city in which they assemble, free of extra cost; petitions and memorials are prepared, forwarded, and printed for circulation to the Legislature, the Medical Council, city corporations, life insurance societies, and wherever required by the honour or interests of the profession; illegal practice and dishonourable practices are put down so far as possible; not less than three times a year the whole body of members is invited to the discussion of subjects of passing or permanent interest; and, altogether, an *esprit de corps* is maintained, which has been of incalculable benefit to the profession.”

The report also tells us that a medical society has been formed at Bury; and that the following resolutions have been lately adopted there:—

“That, in the opinion of this meeting, no practitioner ought to meet in consultation any gentleman who is not duly qualified.” And, “That the members of this Society will not call in consultation any gentleman who is known to meet unqualified or unregistered practitioners.”

IN reading the report of the Bourton-on-the-Water Village Hospital for the year 1862, which has just been presented to us, we are struck by its remarkably economical nature. During the past year, 29 in-patients have been treated in the hospital and 311 out-patients, and the total expenditure was £88, of which sum the patients themselves paid £23. These village hospitals bid fair to open a new era in the administration of medical charity.

WE should like to know upon what principles of justice or common sense medical men are to be compelled to give the following services gratuitously. The following is the clause in the Medical Bill (now passing through Parliament) for the Registration of Births and Deaths in Ireland, under which medical men are bound to give certificates gratis of the cause of death:—

“45. *Medical Attendant to transmit Certificate of Death to Registrar.* Whereas it is expedient to establish on reliable information, for sanitary and scientific purposes, a registration of the causes of death: be it therefore enacted, the registrar shall furnish from time to time, gratis, to every duly qualified medical practitioner within his district, the necessary forms of certificates of deaths in the form (D) hereunto annexed, which certificates the registrar-general shall cause to be printed and forwarded from time to time to every registrar for that purpose; and the medical practitioner who shall have been in attendance during the last illness and until the death of any person dying after the said 31st day of December, 1863, shall, within seven days after the death of such person, transmit to the registrar of the district in which the death occurred a certificate of the cause of death in the form mentioned, the particulars of which shall be entered by the registrar in the register; in case such certificate shall not be so transmitted, the registrar shall transmit to such medical practitioner a form of such certificate, and by a written or printed requisition under his hand shall require such medical practitioner forthwith to return to him such certificate duly filled up, and such medical practitioner shall, within three days after the receipt thereof, return such certificate duly filled up to such registrar.”

## SUICIDE IN THE UNITED STATES.

THE preliminary report of the eighth and last national census of the United States gives statistics of suicides occurring during the year ending the 31st May, 1880. Although no doubt the number of suicides is considerably understated in the census returns, yet it is notorious that the moral atmosphere of America is more favourable to the crop of homicides and murders than to that of suicide. M. Magee, in his work on suicide in Bavaria, lays it down that the frequency of suicide is in inverse ratio to the frequency of crimes of violence. Where, therefore, (as in the United and Confederate States,) homicide is a common occurrence, we may expect to find a scarcity of suicides. The census records 1,002 cases of suicide occurring in the year 1859-60, which gives only 3·2 to every 100,000 of the population; in England and Wales the proportion is 6·7 to every 100,000; in France the rate averages 8·3; in Prussia the rate is about 11 or 12 per 100,000; in the New England States, taken separately (whose returns are as accurate as those of Europe), we find the rate per 100,000 is 7·7. But we must remember this is the great "suicide field" of America: while in our London suicide field the rate is 9·7; in our midland suicide field, 8·4.

Of these 1,002 suicides, 794 were committed by males, and 208 by females; that is, only a little more than a fifth of the whole were females. America has often been said to be the paradise of the female sex. These figures confirm the statement. The proportion of female suicides in England and France, is to males as three to five: in the United States it is but little more than one to five. In the Old World a cast-off mistress commits suicide; in the New she shoots her paramour amid the applause of the community. In some States a woman can compel the father of her illegitimate child to marry her or go to prison. Not only the law, but public opinion and the juries everywhere, espouse the cause of the woman in the United States.

Has this anything to do with the small proportion of female suicides in America? Have our bastardy laws, so severe upon the woman, anything to do with the high proportion that rules among us?

Next as to the method of suicide. We find that hanging is the favourite suicidal resort with both sexes in the United States. This is also the case in every country of Europe of which we have an account, except Sardinia and Geneva, which give the palm to fire-arms. Poison, which occupies the fourth place in English and the seventh in French statistics, holds the second place in the United States. We presume that in that "free country" the laws against the indiscriminate sale of poisons are neither so universal, nor, where existing, so well carried out as in Europe. In England cutting the throat; on the Continent, generally speaking, drowning holds the second place. The fashionable poison in America is strychnine, next arsenic; in England, opium or one of its preparations, then prussic acid. Fire-arms, which stand second with the Saxon, and fifth with the English, stand third with the Americans, as with the French, Belgians, Danes, and many parts of Germany.

On the relation between the rate of suicide and the degree of instruction among any given community, these American returns tell an instructive tale. They entirely corroborate the dicta of M. Lisle, Mr. Radcliffe, and M. Mejan, that the greater the diffusion of instruction the higher the rate of suicide. Thus, take the States where common and collegiate instruction has struck its roots most deeply, where literary tastes have been most cultivated, viz., the New England States and New York, and compare their rate of suicide with the six most populous slave-holding States. The rate of suicide in the former group is as seven to three in the latter in the ratio of their population.

Doubtless, the returns are more accurate for the first group of States than the second, but it would be straining the point too much to contend that this alone will account for such an immense difference of rate—a difference, too, which throughout the whole list of the thirty-four States varies uniformly with the degree of civilisation each State has reached. (*Social Science Review*.)

## Special Correspondence.

## MANCHESTER.

[FROM OUR OWN CORRESPONDENT.]

IT seems strange that there should be a paucity of general medical intelligence to communicate from such a large and important centre of population as this; yet such I find to be the case, more especially since the Medical Society has begun to report its own proceedings in your columns. I by no means wish to be understood that the material for many a valuable addition to medical science is not to be met with both in Manchester and in our other large cities; but that, unfortunately, that material is at present scarcely available. It would be a great achievement if the numerous cases of interest in our provincial hospitals and dispensaries could be brought together into one fund; and I have made some exertions to see if this could not be done here. Two general hospitals, two hospitals for children, one for female complaints, and one each for the eye and ear, with a lock hospital, and four or five dispensaries, would furnish no slight amount of interesting matter. I find a general willingness on the part of all the medical officers of these institutions whom I have consulted to aid in such a scheme; but the whole thing falls through from the almost entire absence of general and accurate case-reporting at the institutions themselves, it being manifestly beyond the power of one individual to undertake the task. Perhaps, some day, this may be remedied; and, in the meantime, as I have formerly said, I have an objection to recording even very interesting cases that may occur merely to myself or my own more immediate acquaintance.

The late debate on Dr. Noble's paper on Diabetes was of some interest. The cases to which he drew attention had been pronounced, upon good metropolitan authority, to be diabetes from the mere existence of saccharine urine in tolerably large quantity; but there was a complete absence of the usual attendant symptoms, and the cases eventually did well under ordinary regimen and care, and under the cessation from severe head work, to which he entirely attributed the disease. In the present state of our knowledge, it would appear inadvisable to apply the term diabetes to such cases. As maintained by Dr. Roberts, one of the links in the chain of production of diabetes is undoubtedly to be found in the nervous centres; but the links anterior or posterior to this may perhaps vary considerably, and thus alter the whole complexion and gravity of the case.

Our two societies have been holding their annual meetings, and taking stock, as it were, of their doings; and I rejoice that the Medical Society has at last been bold enough and honest enough to raise its subscrip-

tion, and that it will thus be able, while it pays its debts, to increase the value of its library, and generally so to increase the attractions of the institution, as to make it a sort of dépôt for the medical talent and intelligence of this great provincial metropolis.

The Medico-Ethical had also a pleasant assembly, and, though the numbers have slightly fallen off, there is an evident determination to propagate their excellent code of laws, and to follow up their views on medical reform and on the amendment of the functions of coroners. On this latter matter, I trust they will persevere as they have begun. I hope to see the day ere long when this society, while preserving some of its individual social features, shall enter into more intimate alliance with the British Medical Association.

Some of your readers will doubtless be puzzled at the contradictory accounts, emanating from various sources, as to our sanitary condition here under the present distress. The subject is rather too complicated for full discussion now. The *Times* is, of course, at sea on the matter, as it seems impossible to avoid being on anything and everything connected with Lancashire. While it gives very undue prominence to Dr. Buchanan's remarks on the existence of typhus—much more than he does himself—it must needs at the same time write a leading article to show that we are either in the best of health, and spirits, and circumstances, or that, as with Mark Tapley, our difficulties are only evidenced by our "jolly" demeanour. I am glad to be able to say with great confidence, apart from statistics, that there is not a large amount of sickness prevalent in Manchester, and this is strongly borne out by the very low death-rate. The statistics of admission to hospitals and dispensaries are, of course, no criterion of the amount of illness, as they vary with the poverty of the people. The relative forms of sickness are more important. Thus, contrary to what might be expected, diarrhœa seems to have been unusually low; for, comparing Manchester with St. Marylebone, I find the proportion to the whole, during September, October, and November, to have been 5·8 per cent. in the former, and as much as 14·8 per cent. in the latter. I regret that I have no means of ascertaining the comparative proportion of tubercular complaints, as they are not separately tabulated by our Sanitary Association returns; but under the combined heads of pneumonia, pleurisy, bronchitis, and catarrh, I find that, during the same months, Marylebone showed a proportion of 13·7 per cent. against 23·1 per cent. in Manchester. Making allowance for our northern climate, this would tend to show a greater severity of pulmonary complaints, many of which must doubtless be connected, as cause or effect, with tuberculosis.

I have noticed myself an infrequency of rachitis among infants, and I find that others have observed the same thing. Doubtless, the greater supply of maternal milk has to do with this, and, perhaps, also, in a small degree, the unusual frequency of oatmeal as an article of diet. I am greatly mistaken, however, if this benefit be not more than counterbalanced by the greater frequency of tuberculosis in children a little older. They are the greatest sufferers by the present distress, as the relief committees do not generally include in their sup-

plies such articles as milk, arrow-root, or other things suitable for a change of diet in childhood. The results of this are to be looked for in the death-rates of future years, or even of a future generation.

The question of typhus has been much discussed in the pages of your own and other journals, and the report of Dr. Buchanan sharply criticised. There can be no doubt that there is nothing like an epidemic of true typhus in Manchester. But that there have been several cases, seen by Dr. Buchanan himself, and reported on trustworthy authority, is also undoubted. This is sufficient to make us watchful without undue alarm; for true typhus has for some years been very rare here. In five years of dispensary practice, I have not seen a single case; and I attach no importance whatever to the annual return of a few cases, unless it were stated that the diagnosis between typhus and enteric fever had been carefully insisted on. I myself know of several instances of the latter returned as typhus by a gentleman who, though a very sound practitioner, will maintain that there is no distinction between the two; and I suspect there must be many others so returned for the same reason, or from indifference. If it be not so, at any rate, our Manchester practitioners must, as a body, be considerably ahead of their brethren in exactitude. Our infirmary physicians are decidedly of opinion that true typhus began for a time to show itself in very undue proportion to enteric fevers; and I believe they are also agreed that this proportion has again fallen to something like its normal limits. I think also it might be shown that this fall in the number of cases of typhus took place just about the time that the relief committees began to raise their scale above the mere average of two shillings per head, and also when the distribution of clothing was made. On the whole, these bodies have done their work well, and have hitherto maintained the health of the operatives at a far higher standard than might have been expected; and I must close my remarks by assuring you that the medical profession has not been behind in assisting to promote their endeavours.

A MAGAZINE devoted to the science of botany is about being started by Mr. Hardwicke, to be called *The Journal of Botany, British and Foreign*, edited by Dr. Seemann.

LONDON FEVER HOSPITAL. On Friday week, the annual general court of this charity was held at the Freemasons' Tavern; the Right Hon. the Earl of Devon in the chair. The total number of admissions, which in 1860 did not exceed 391, and in 1861 did not exceed 646, in 1862 amounted to 2699, being 938 in excess of the largest number of patients admitted in any previous year since the foundation of the hospital. The great increase was mainly due to the prevalence of typhus fever. The report alluded to the reprehensible practice of employing street cabs for the conveyance of patients suffering from infectious diseases. The hospital had for several years been provided with a carriage especially adapted for this purpose, which could be sent to any part of London; the committee, however, regretted that, owing to the limited funds, they were compelled to charge patients for horse-hire on each occasion, and that, consequently, the carriage was less used than it ought to be. The public were therefore invited to contribute towards a special fund for the maintenance of such carriage.

# Association Intelligence.

## NEW MEMBERS OF THE ASSOCIATION.

THE following new members have joined the Association since the publication of the list on August 23rd, 1862; most of them since the commencement of the present year.

### BUCKINGHAMSHIRE.

Death, Robert, Esq., Buckingham  
Duke, Frederick, Esq., Buckingham  
Knight, Thomas, Esq., Brill  
Nixon, Daniel, Esq., Stony Stratford  
Savory, John Thomas, Esq., Weudover  
Walker, William G., Esq., Brill  
Warren, Thomas A., Esq., Princes Risborough

### CHESHIRE.

Renshaw, Charles J., M.D., Altrincham  
Stevenson, John F., M.D., Birkenhead  
Thompson, Moses D., Esq., Stalebridge  
Weaver, Frederick P., M.B., Frodsham

### DERBYSHIRE.

Shore, Ofley B., M.D., Physician to the General Infirmary, Derby  
Webb, William, M.D., Wirksworth

### DEVONSHIRE.

Feunise, Andrew, L.R.C.P.Ed., Lymptone  
May, John H. S., Esq., Plymouth  
Scott, Andrew J., M.D., Tiverton

### DORSETSHIRE.

Hingeston, William, Esq., Lyme Regis

### DURHAM.

Bennett, Francis, Esq., Surgeon to the Dispensary, Gateshead  
Parker, Thomas P., M.D., Consulting Physician to the Infirmary, Sunderland  
Watson, Henry W., Esq., Burnopfield

### ESSEX.

Gimson, William G., M.D., Witham  
Hamilton, Jno. B., L.R.C.P.Ed., Caroline Villas, Leytonstone Road  
Reynolds, Robert, Esq., Steeple Bumpstead

### GLOUCESTERSHIRE.

Brush, James R., M.D., Stoke Bishop, Clifton  
Clark, Thomas E., Esq., Lecturer on Botany in the Bristol Medical School, Clifton  
Fegen, W., Esq., H.M.S. *Dædalus*, Bristol  
Graves, Ryves W., Esq., Surgeon to the Infirmary, Gloucester  
Kedell, George, Esq., Bristol  
Rogers, George, M.D., Bristol  
Wilson, Edwd. T., M.D., Physician to the Dispensary, Cheltenham

### HAMPSHIRE.

Case, William, L.R.C.P.Ed., Fareham  
Harvey, J. A. R., M.D., R.N., Southsea  
Norman, Henry B., Esq., Surgeon to the Portsmouth, Portsea, and Gosport Hospital, Southsea  
Parson, Edward K., Esq., Senior Surgeon to the Portsmouth, Portsea, and Gosport Hospital, Southsea

### HEREFORDSHIRE.

Beavan, James, Esq., House-Surgeon to the Infirmary, Hereford  
Smith, Joseph E., Esq., Ewins Harold

### HERTFORDSHIRE.

Russell, William A., L.R.C.P.Ed., St. Alban's  
Whately, Thomas, Esq., Berkhamstead

### HUNTINGDONSHIRE.

Wright, Samuel, Esq., St. Neot's

### LANCASHIRE.

Coveney, James H., Esq., Prestwich  
Davies, Thomas P., Esq., Pendleton  
Leete, Edward S., Esq., Newton-le-Willows  
Lowndes, Henry, Esq., Junior Surgeon to the Northern Hospital, Liverpool  
McNicol, David H., M.D., Southport  
Parks, John, Esq., Bury  
Roberts, David L., M.D., Surgeon to St. Mary's Hospital, Manchester

Samelson, Adolph, M.D., Surgeon to the Eye Hospital, Manchester  
Smart, Robert B., Esq., Surgeon to the Hospital for Children, Manchester

Williams, John, M.D., Alderley Edge

### LINCOLNSHIRE.

Garnham, Devereux J., Esq., House-surgeon to the General Dispensary, Lincoln  
Harvey, Richard S., Esq., Lincoln  
Hewson, John S., Esq., Senior Surgeon to the County Hospital, Lincoln

### MIDDLESEX.

Atkins, J. R., M.D., Grove House Asylum, Stoke Newington Green  
Barker, Alfred J., M.D., Upper Holloway  
Blackstone, Joseph, Esq., Gloucester Road, Regent's Park  
Bridgeman, George W., Esq., 73, Margaret Street

Bryant, Thomas, Esq., Assistant-Surgeon to Guy's Hospital, Finsbury Square

Burrows, William A., Esq., Quadrant Villa, Islington  
Cabill, Thomas, M.D., Albert Terrace, Knightsbridge  
Challice, John, M.D., Great Cumberland Street

Clark, Alfred, Esq., Twickenham

Clark, Andrew, M.D., Assistant-Physician to the London Hospital,

Montague Street, Russell Square

Cornack, John Rose M.D., Bedford Square

Dick, Henry, M.D., Wimpole Street

Dixon, Thomas, M.D., Forchester Place, Bayswater

Dow, John, Esq., St. Martin-le-Grand

Edwards, D. O., Esq., Gilston Road, Brompton

Eyles, Richard S., Esq., St. Devon's Court, Holborn

Forbes, John Gregory, Esq., Devonport Street, Hyde Park

Forstyth, John, Esq., C.B., late Bengal Medical Service, Oriental Club

Fraser, Donald, M.D., Harrington Square

Galton, Robert Cameron, M.D., Harley Street

Gibson, Jno. R., Esq., Surgeon to Newgate Prison, Russell Square

Grant, Alexander, Esq., late Bengal Medical Service, Park Road, Haverstock Hill

Hawkins, Francis, M.D., Registrar to the Medical Council, Bolton Street

Hayward, Henry H., Esq., Queen Anne Street

Headland, Edward, Esq., Upper Portland Place

Holt, B., Esq., Surgeon to the Westminster Hospital, Savile Row

Hunt, Alfred, Esq., Hammersmith

Kelly, Hubert E. C., M.D., Pinner

Kisch, Joseph, Esq., Circus Place, Finsbury

Kitching, George, M.D., Enfield

Langmore, John C., M.B., Oxford Terrace

Latham, Peter M., M.D., Grosvenor Street

Leared, Arthur, M.D., Physician to the Great Northern Hospital, Old Burlington Street

Lee, Newton B. C., Esq., Talbot Terrace, Westbourne Park

MacKmurdo, Gilbert, Esq., F.R.S., Surgeon to St. Thomas's Hospital, New Broad Street

Mapleton, Henry, M.D., Inspector General, Army Medical Department, Whitehall Yard

Musket, William B., M.B., Fulham

Norton, Robert, M.D., Westbourne Grove West

Pearse, George, L.R.C.P.Ed., Regent Street, Westminster

Phillips, Richard, Esq., Leinster Square

Randall, John, M.D., Medical Officer to St. Marylebone Infirmary, Portman Street

Rose, Henry Cooper, M.D., Hampstead

Sankey, William H. O., M.D., Asylum, Hanwell

Skey, Frederick C., Esq., Surgeon to St. Bartholomew's Hospital, Grosvenor Street

Slyman, William D., Esq., Wellington Road, Kentish Town

Smith, Thomas, Esq., Demonstrator of Anatomy at St. Bartholomew's Hospital, Montague Street

Smith, Wm. A., M.D., Physician to the City Dispensary, Doughty Street

Stone, Thomas A., Esq., Grosvenor Street

Witten, Edward W., Esq., Gibson Square

### MONMOUTHSHIRE.

Davies, Benjamin, M.D., Newport

### NORFOLK.

Aldred, Charles C., Esq., Great Yarmouth

Clouting, John R., Esq., Shipdham

Johnson, W. H., Esq., Thetford

Palmer, Charles, Esq., Surgeon to the Hospital, Great Yarmouth

Peurice, David S., Esq., Tombland, Norwich

Rump, Hugh R., Esq., Wells

Smyth, Spencer T., M.D., Senior Surgeon to the Hospital, Great Yarmouth

Vores, William, M.D., Great Yarmouth

### NORTHAMPTONSHIRE.

Bolland, Edward H., M.D., Daventry

Dudley, Edward, Esq., Yardley Hastings

### NORTHUMBERLAND.

Candlish, Henry, M.D., House-Surgeon to the Infirmary, Alnwick

Gibb, Chas. J., M.D., Surgeon to the Infirmary, Newcastle-on-Tyne

### NOTTINGHAMSHIRE.

Stevenson, Frederick, Esq., Nottingham

### SHROPSHIRE.

Beddoes, William M., M.D., Shrewsbury

Brook, Henry, Esq., Bishop's Castle

Eddowes, William, jun., Esq., House-Surgeon to the Infirmary, Shrewsbury

Willing, George F. B., Esq., Cressage

### SOMERSET.

Gaine, Charles, Esq., Bath

Kinglake, Hamilton, M.D., Taunton

### STAFFORDSHIRE.

Girdlestone, William T., Esq., Penkridge

Proctor, Herbert E., L.R.C.P.Ed., Wednesbury

### SUFFOLK.

Blackett, Edwd. R., M.D., Physician to the Dispensary, Southwold

Elliston, William, M.D., Ipswich

Smith, Charles C., Esq., Consulting Surgeon to the Suffolk General Hospital, Bury St. Edmunds

## SURREY.

Clark, F. Le Gros, Esq., Surgeon to St. Thomas's Hospital, St. Thomas's Street, Southwark  
 Rendle, James D., M.D., Medical Officer to the Government Convict Prison, Brixton Hill  
 Spitta, Robert J., M.D., Medical Officer to the Clapham Dispensary, Clapham Common

## SUSSEX.

Adey, Charles A., M.D., Physician to the East Sussex Infirmary, St. Leonard's-on-Sea  
 Dill, Richard, M.D., Brighton  
 Taylor, William E., M.D., Pulborough

## WARWICKSHIRE.

Foster, Balthazar W., L.K. & Q.C.P.L., Medical Tutor, Queen's College, Birmingham  
 Robinson, Edmund, Esq., Birmingham

## WILTSHIRE.

Vicary, Charles, Esq., Warminster

## WORCESTERSHIRE.

Roden, William, M.D., Kidderminster

## YORKSHIRE.

Dadley, John W. F., Esq., Farington  
 Harrison, Samuel N., Esq., Farington  
 Roberts, Edward S., Esq., Hull

## WALES.

Covernton, Charles J., L.R.C.P. Ed., Knighton  
 Gilbertson, Richard, Esq., Aberystwith  
 Harrison, Reginald, Esq., Merthyr Tydfil  
 Jones, Richard, M.D., Newtown  
 Jones, Watkin W., Esq., Ruthin  
 Phillips, George, Esq., Haverfordwest

## SCOTLAND.

Alexander, James, Esq., Leslie, Fife  
 Branwell, James P., M.D., Perth  
 Christie, James, M.D., Consulting Physician to the Royal Infirmary, Dundee  
 Dougal, Daniel, M.D., Strathaven, Lanarkshire  
 Dunbar, Henry, M.D., Glasgow  
 Dyce, Robert, M.D., Senior Physician to the Royal Infirmary, Aberdeen  
 Easton, John A., M.D., Professor of Materia Medica in the University, Glasgow  
 Fairless, William D., M.D., Medical Superintendent of the Old Royal Lunatic Asylum, Montrose  
 Ferguson, John, Esq., Oak Bank, Mull, Oban  
 Gilchrist, James, M.D., Medical Superintendent, Crichton Royal Institution, Dumfries  
 Kelly, Adam L., M.D., Glasgow  
 Lister, Joseph, M.B., F.R.S., Professor of Surgery in the University, and Surgeon to the Royal Infirmary, Glasgow  
 McColl, Hector, Esq., Tobermory, Argyshire  
 Mackie, George, M.B., Insch, Aberdeenshire  
 Macrae, Donald, Esq., Harris, Stornoway  
 Prichard, William, M.D., Partick, Glasgow  
 Ritchie, Charles, M.D., Physician to the Royal Infirmary, Glasgow  
 Scott, Thomas A. F., Esq., Lochmaben, Dumfriesshire  
 Sloan, Charles F., M.D., Ayr  
 Spence, James, Esq., Surgeon to the Royal Infirmary, and Lecturer on Clinical Surgery, Edinburgh  
 Thomson, Allen, M.D., F.R.S.L. & E., Professor of Anatomy in the University, College, Glasgow

## IRELAND.

Beamish, William, M.D., Physician to the Fever Hospital, Cork  
 Berry, Parsons, Esq., Mallow  
 Corry, Thomas C. S., M.D., Belfast  
 Croker, Charles P., Esq., Consulting Physician to Stevens' Hospital, Dublin  
 Hegarty, William, M.D., Kinsale  
 Neilson, Charles, Esq., Killala, Mayo  
 Ormston, Henry B., M.D., Bandon, Cork  
 Payne, Christopher J., M.D., Roundstone, Galway  
 Sproule, Jacob, Esq., Arvagh, Cavan  
 Stephenson, Robert, M.R.C.P. Lond., Belfast

## BRANCH MEETINGS TO BE HELD.

NAME OF BRANCH.	PLACE OF MEETING.	DATE.
LANCASH. & CHESHIRE. [Ordinary.]	Royal Institution, Manchester.	Thursday, March 12th, 3 P.M.

## NOTICE REGARDING NEW MEMBERS.

By desire of the Committee of Council, the General Secretary requests that the Local Secretaries will be good enough to forward to him the names of all New Members who join the Association through the Branches; as otherwise the JOURNAL cannot be sent to them.

PHILIP H. WILLIAMS, M.D., *General Secretary.*

Worcester, November 10th, 1862.

## LANCASHIRE AND CHESHIRE BRANCH.

An ordinary meeting of this Branch will be held at the Royal Institution, Manchester, on Thursday, March 12, at 3 P.M. Notice of papers, etc., to be sent to the Honorary Secretary.

Dinner will be provided at the Clarence Hotel, Spring Gardens, at 5 o'clock.

A. T. H. WATERS, M.D., *Honorary Secretary.*

Liverpool, February 16th, 1863.

## BATH AND BRISTOL BRANCH: ORDINARY MEETING.

An ordinary meeting of the Bath and Bristol Branch was held at the Athenæum, Bristol, on February 26th, 1863; W. J. CHURCH, Esq., President, in the Chair. There were present forty-four members and thirteen visitors.

The minutes of the last ordinary meeting were read and confirmed.

*New Member.* George Rogers, M.D., was elected a member of the Association and of the Branch.

*Papers.* The following papers were read:—

1. Case of Obstruction of the Bowels. By J. Deddoe, M.D.
2. Case of Cæsarian Section. By R. W. Coe, Esq.
3. Cases of Puerperal Convulsions, with remarks. By J. G. Swayne, M.D.
4. Case of Puerperal Convulsions. By S. H. Swayne, Esq.
5. On the Use of Metallic Ligatures. By W. M. Clarke, Esq.

Several other papers had to be postponed on account of the late hour of the evening.

The papers read will be sent to the JOURNAL for publication.

## Reports of Societies.

## LIVERPOOL MEDICAL INSTITUTION.

FEBRUARY 5, 1863.

A. B. STEELE, Esq., Vice-President, in the Chair.

*Small-Pox.* The CHAIRMAN remarked that he had just had a fatal case of small-pox. The patient, who had never been vaccinated, had the disease in its completest form; and the eruption appeared in great intensity on the body and limbs. A man in the same house who had been vaccinated, had the disease in a mild form, and was recovering when this patient was taken ill.

Mr. FLETCHER said that there was no case of small-pox at present in the workhouse, and that there had been very little of late; but fever was still very prevalent, and twenty-nine cases were admitted into the Fever Hospital last Wednesday.

*Malignant Disease of the Eye.* Mr. BICKERTON shewed an eye affected with malignant disease, which he had extirpated.

*Fibro-cystic Tumour of the Uterus.* Mr. HAKES shewed a specimen of this form of disease which he had removed from a married woman, aged 42. She had two children, the youngest of whom is about 15 years old. She first noticed the tumour in September 1861, and she came to be tapped in February 1862. [The case was reported in the letter of our Liverpool correspondent last week.]

Mr. Hakes thought it almost impossible to diagnose in some cases between uterine and ovarian tumours.

Mr. FLETCHER said it was singular there should have been two fibro-cystic tumours of the uterus removed in

Liverpool in one year. In the case he himself had operated on, there was more solid matter in the tumour. These cases were very rare. This fatal case of Mr. Hakes did not much affect the question as to whether we should operate in cases of uterine tumour. Failure of strength seemed the only cause of death, and the state of the peduncle and other parts concerned in the operation was encouraging.

Mr. HIGGINSON suggested that in tying the peduncle, in some cases, a thread might be included in the ligature, with which the wire might be brought out if the woman lived.

Mr. FLETCHER thought the thread itself would be a great source of irritation, whereas we have no evidence of any disturbance being caused by the presence of the wire.

The CHAIRMAN said that, out of eleven cases, operated on in Liverpool for ovarian disease, there had been five recoveries and six deaths.

Mr. DENTON observed that we are told that an age past the meridian of life is favourable, and that so is also a moderate amount of inflammation. In this case there were both of these requisites, and still a fatal result.

*Hydatidiform Degeneration of the Ovum.* Dr. GRAMHAM shewed a specimen.

*Ligature of the Internal Iliac Artery.* Mr. HIGGINSON shewed a portion of the internal iliac artery to which he had applied a ligature in a case of hæmorrhage in the gluteal region. A man named Thomas Carroll was admitted into the Liverpool Southern Hospital, on January 4th, 1863. Five weeks previously, he had fallen off a railway bridge and received severe contusions about the hips and back. He was under the care of Dr. Thomson of Aigburth, and recovered so far as to be able to walk a mile to mass; but this exertion was followed by considerable pain and swelling in the gluteal region, with much irritative fever. A small opening was made on December 21st, in the most prominent part, and a little sero-purulent matter escaped, without any diminution of the swelling. Four days after, as the man was attempting to get out of bed, a copious discharge of blood took place from the incision, but was easily stopped by pressure. For some days there was a copious discharge of bloody pus, and on January 2nd, there was a second sudden gush of blood, which was again easily checked by pressure. Dr. Thomson now sent the man to the Southern Hospital.

On his admission, Mr. Higginson removed the compress, and great hæmorrhage immediately ensued. He found a deep space full of gangrenous tissue and blood; on examining the surrounding parts, he found a spot which was soft and inflamed, and into it he passed a grooved needle, and a little bloody fluid oozed out. Soon afterwards, a great gush of blood took place; Mr. Higginson then passed his finger into the wound and turned out a clot, and found that the wound extended deeply down towards the sacro-sciatic notch. He now plugged the wound; and, in consultation with Dr. Nottingham, decided to perform ligature of the internal iliac artery. The man was very low and weak. The operation was performed at 8 P.M. by Mr. Higginson, without much difficulty, and without any loss of blood. The man died at 10 the following morning. Mr. Higginson said that, if he had known how rapidly the man was sinking, he would have performed transfusion. On examination after death, Mr. Higginson found there was a fracture of the sacrum near the attachment of the sacro-iliac ligaments; the tissues about were much infiltrated with blood, and the gluteus maximus was much separated from its attachments. The exact point from which the bleeding had proceeded could not be discerned.

Mr. Higginson remarked that, if he regretted anything in regard to this case, it was that he had not resorted to transfusion of blood, and, in support of the propriety of

this proceeding, he cited the following instance of its successful employment.

J. C., aged 51, a ship-carpenter, came into the Southern Hospital on May 18th, 1860, with inflammation of the front of the left forearm. On the 12th, an incision was made through tissues tense with infiltrated serum, but no pus flowed at the time. The discharge soon became purulent, and great burrowing of matter, and sloughing of cellular tissue throughout the forearm took place, and free openings were made from time to time. He had two sudden attacks of hæmorrhage from these sinuses prior to June 16th; but on that day a more alarming gush took place, and the brachial artery was tied at the elbow. He lost no more blood, but the state of the arm pointed to the necessity for amputation; while, on consultation, the patient was thought too much prostrated to bear it.

On the 17th, as he had not at all rallied, but rather the reverse, transfusion was performed by Mr. Higginson, by injecting into the sound arm about twelve ounces of blood taken from the man's daughter-in-law. The patient now improved so satisfactorily that on the 18th, the diseased arm was removed above the elbow. He made good progress until the 24th, when the left leg and thigh became enormously swelled and of a purple hue, and the circulation in the limb seemed arrested. This swelling gave way, however, to frictions with lard, and the free use of rum and milk as diet. He left the hospital, cured, twelve weeks after admission.

Dr. THOMPSON mentioned two other cases, that had come under his notice, of severe hæmorrhage in the gluteal region. In one, a marine received a wound which was followed by alarming bleeding, but this was arrested by pressure. In the other, a boy, four years old, was wounded with a knife, and the hæmorrhage that ensued could not be completely stopped by pressure; Dr. Thompson would have tied the internal iliac, but the child's parents would not consent. The boy was taken to Dublin, and was under the care of Colles and others, and they would have tied the internal iliac, had not the child died in the meantime.

The CHAIRMAN asked if the great principle of cutting down to the bleeding vessel, and tying it above and below the bleeding point, could not be applied to these cases.

Mr. HIGGINSON said this case must be considered almost aneurismal in its nature. If any one had attempted to search for the wounded vessels, what difficulties he must have encountered; the man was fleshy and the cavity deep; the gush of blood would have been excessive unless the abdominal aorta were compressed.

Mr. HAKES said that often, where there are large collections of blood and great hæmorrhage, laying the cavity freely open will suffice to stop the bleeding. He had seen such the case in abscesses in the neck and scrotum. In this case, perhaps, some little vessel might have been found bleeding, and secured. He thought this would have been better than proceeding to so serious an operation; or, again, it might have been better, as the bleeding was stopped for the time, to have done nothing, and waited for further indications.

Mr. FLETCHER alluded to the case of Mr. Seaton, in Mr. Liston's practice. He thought in a case like that of Mr. Higginson we ought to tie the gluteal artery, if possible; with regard to compressing the aorta, Mr. Syme cut into an aneurism, and tied the external, internal, and common iliac, compressing the aorta in the meantime.

Mr. HIGGINSON could not agree that it would have been safe or prudent to open out the cavity and search for the vessel; the blood welled up copiously from a great depth, and might have proceeded from some vessel quite within the pelvis.

*Empyema in a Child, for which Paracentesis was Performed.* Mr. HODGSON read a case. The child had re-

cently had scarlatina and measles, a very short time before. The empyema appeared to have come on without any very acute symptoms of pleurisy. On November 20th, 1862, the child was sitting erect, with great dyspnoea, and on examining the chest, Mr. Hodgson found the left pleura full of fluid, the heart pushed to one side, and great distension of the abdomen. The presence of pus was diagnosed from some appearance of pointing. The operation was performed by Mr. Higginson, on December 13th, and a pint of pus evacuated with great relief; on the 24th, the operation was repeated, and the child died two days afterwards.

The left lung was found to be compressed against the vertebrae, and completely condensed; the heart pushed to the right side. There was a mulberry calculus in the right kidney. Mr. Higginson thought the operation had been deferred too long in this case. The lung was excessively compressed, and the walls of the thorax rigid.

Dr. Vose alluded to the hopeless nature of these cases in general. The lung was shrunken, carnified, more like the sole of an old boot than a lung; its tint is all of lung that remains. As an operation for the cure of empyema, paracentesis was most unpromising; but where there is hopeless dyspnoea, and syncope is threatened, we have no alternative but to give what relief the operation affords.

Dr. CALLON mentioned a case in which paracentesis had been performed, with only a partial escape of the fluid. After death, the pleural cavity was found divided into two by adhesions, and the surfaces covered with medullary cancer.

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, FEBRUARY 24TH, 1863.

B. G. BABINGTON, M.D., F.R.S., President, in the Chair.

REMARKS ON TWO CASES OF KELIS. (WITH PHOTOGRAPHS AND COLOURED DRAWINGS.) BY DEPUTY INSPECTOR-GENERAL T. LONGMORE.

The writer referred to the paper by the late Dr. Addison, in the thirty-seventh volume of the Society's *Transactions*, on the Keloid of Alibert, and on that form of Kelis which he (Dr. Addison) considered to be of a distinct character, and which he designated True Keloid. The two cases now brought to the notice of the Society were very striking illustrations of these two forms of keloid disease; but the writer was led to question whether evidence was not afforded by them that they were only simple varieties of one and the same affection, dependent upon the same keloid constitution of the dermal tissue, and owing their different features solely to the differences in the exciting causes.

In the first case the disease was developed after punishment by flogging, of a comparatively light nature. There was scarcely any laceration of the skin. About three months after the date of punishment the soldier noticed a growth upon the spot where the flogging had been chiefly received. This growth gradually increased from a small round tubercle to a large flat mass, nearly as large as a man's hand. It was not accompanied with pain, but there was irritability, itching, and tenderness, when the part was subjected to the pressure of the cross-belt and weight of the knapsack. On the front of the patient's chest were several small tumours, evidently of the same nature, but the date of the first appearance of those growths could not be ascertained.

The disease in the second case was more extensive than had been described by any writer hitherto, and presented a most remarkable appearance. It was of the kind which Dr. Addison considered should be separated from the former variety under the name of "true keloid." The patient, a cavalry soldier of strong powerful frame,

went to India with his regiment in November, 1857. Five months afterwards, at the commencement of the hot season, he began to suffer from lichen tropicus, in common with all the other men of the regiment. About a month afterwards the keloid disease began to show itself, in the form of a few prominent red tubercles on the right forearm. It next appeared over the middle of the sternum, and thence extended gradually towards the two sides of the body. At the same time it appeared on the left shoulder and various parts of the back, and continued to spread until it had covered the entire dorsal surface of the body. The skin of the face was also affected.

The physical characters and accompanying symptoms of the disease in both instances were fully described in the historical accounts of the cases presented to the Society. Their characteristic features were represented in the drawings and photographs.

The writer urged that no two more striking examples of the two species, "true keloid" and "spurious keloid," according to those who designate them as distinct species, could be met with than the cases brought to the notice of the Society. He argued, however, that, in the case in which the kelis was excited by flogging, the comparative slightness of the punishment, the rarity of such a consequence, but more particularly the presence of the keloid spots in their favourite habitat—the skin covering the anterior part of the chest,—established the constitutional nature of the disease, just as fully as it was established in the second case, where it appeared to follow the excitement of the prickly heat. The fact, too, that the general characters of the diseased growths in both instances were alike, and that in each instance the hypertrophy was greatest where the pressure of the cross-belt was chiefly exerted, confirmed still further the identity of their nature. The deduction was hence drawn, that, both the patients being of a keloid diathesis, the difference in the mode of distribution, and in some of the features, of the diseased growths in the two cases could be accounted for by the different natures of the exciting causes.

No treatment had appeared to exert permanent beneficial change in either case. The fact that the pressure of the cross-belt acted in each instance as a stimulus to increased growth was held to be a sufficient argument against treatment by continued pressure, which had been recommended by some surgeons. The evidence of the constitutional origin in the case where the chief tumour was isolated upon the left shoulder, as well as the nature of the immediately exciting cause, had counter-indicated any attempt at cure by extirpation.

AN ESTIMATE OF THE EXTENT TO WHICH HUMAN LIFE HAS BEEN PROLONGED OR ABRIDGED BY OVIOTOMY. BY ROBERT LEE, M.D., F.R.S.

Dr. LEE, after stating that statistical tables of ovariectomy had been compiled with great labour at different periods by various eminent individuals, proceeded to analyse the tables of Dr. Clay published in 1860, which comprised in all 567 cases. Of these, 242 were considered successful, and in 235 the patients died from the direct effects of the operation. If 477 cases were deducted from 567, there remained 90 cases. Whether, however, life was prolonged or abridged in these cases, Dr. Lee could not state, as he had been furnished with no information on the subject. The author averred that since 1860 the operation of ovariectomy had been performed in numerous cases in Great Britain, and that a number of fatal cases had occurred of which no report had been published. In illustration of this statement, he gave brief accounts of thirteen unsuccessful cases, not hitherto published, of which he had obtained information. Dr. Lee concluded his remarks with the statement that he considered it demonstrated that ovariectomy was an unjustifiable operation where the life of

the patient was not in immediate danger, and where there was not a great probability of the life of the patient being saved by the removal of the disease.

## WESTERN MEDICAL AND SURGICAL SOCIETY.

FRIDAY, FEB. 20TH.

M. BAINES, M.D., Vice-President, in the Chair.

### ON THE THERAPEUTICAL VALUE OF COD-LIVER OIL IN CHRONIC CONVULSIVE DISEASES.

BY F. E. ANSTIE, M.D.

THE author's attention had first been directed to cod-liver oil as a remedy for affections of this class, in consequence of his obtaining some years ago an unexpected success with it in a case of chorea which had resisted all the ordinary modes of treatment. The convulsive diseases in which the author has employed cod liver oil are paralysis agitans, simple epilepsy, chorea and mercurial tremor, and in all these affections it has appeared to be more constantly useful than any other medicine. Of paralysis agitans, four cases were detailed, of which three were very decidedly improved and one of them may have been said to be cured, although the affection had been very severe. Of chorea, one case was detailed, and others were alluded to in which the benefit produced was very marked. Of mercurial tremor, one most remarkable case was related, in which the cause of the mischief was a very unnecessary salivation inflicted by medical authority some thirty years previously; the patient was attacked immediately afterwards with dreadful tearing pain in the muscles of the fore arms and calves, and with violent muscular tremors; and, ever since that time, she has been liable to a recurrence of the symptoms when much fatigued or depressed from any cause. On application to Dr. ANSTIE, at the Chelsea Dispensary, cod-liver oil was prescribed and persisted with for five weeks, at the end of which time, all the symptoms had perfectly disappeared; the patient declared that she had never been cured before in less than six or eight months, and she doubted whether any other medicine than the oil had ever really done her any good. Twice since she has had slight recurrence of the symptoms, but a short course of cod liver oil has, on each occasion, given complete relief. Of simple epilepsy, twenty cases were given, in which the treatment had been confined to the use of cod-liver oil. Of these, there were five upon whom no good effect whatever was produced; seven had completely recovered; two had disappeared from supervision at a time when they were rapidly improving, although they could not be said to be cured; in two others the mental symptoms had greatly improved, but the fits remained as before; four patients remain still under supervision; in two, fits have ceased, although there are still frequent prodromata; and in the remaining two but little good has yet been effected. Besides this general summary of results, Dr. ANSTIE detailed the particulars of three cases which, from their severity, might be said fairly to test the remedial power of the oil. The patients were respectively a girl aged 17, a boy aged 13, and an infant aged 7 months, in all of them the fits were very frequent and severe, and the nervous system exhibited signs of great depression. The case of the infant was specially noticeable, because it was proved by microscopic inspection that the milk of the mother was very deficient in oily matter, and it appeared that in a former infant of the same mother precisely the same train of symptoms had appeared, and had terminated fatally. In all these three cases, the treatment had proved perfectly successful, and the author commented strongly on the fact, that in all these cases the general nutrition of the body had been excellent, and only that of the nervous system had appeared deficient, and said the conclusion appeared inevitable, that the oil had expended itself in enriching the nervous centres. This,

indeed, was the principal point of the paper. The author directed attention to Dr. Radcliffe's remarks on the necessity of fat to the nutrition of the nervous centres, and mentioned the fact that that gentleman had found cod-liver oil of the highest value in the treatment of convulsive diseases. He observed also, that the beneficial action of cod-liver oil was quite consistent with what we know of the action of the few other remedies which careful therapeutical investigation has credited with a really beneficial action in chronic convulsive diseases. Steel, arsenic, quinine, all these may fairly be spoken of as foods.

With regard to sedatives, the author remarked that, in the first place, the good effects which could be expected from them were chiefly temporary and such as result from breaking through for a time the evil habit, so to speak, of convulsive action. Secondly (and this was most important), there was strong reason to believe that it is not the really narcotic effect of these remedies which are of service in preventing or arresting convulsive action; but merely the stimulant effects which can be obtained from small doses; for there is no class of remedies which is more useful in preventing or arresting convulsions than the pure stimulants. The author concluded his paper by deprecating strongly any return to the absurd system of hunting about blindly for specifics for chronic convulsive diseases. The progress of clinical observation was blasting the reputation of one after another of the strange out of the way remedies, which had once been accepted with the blindest faith, and was pointing unmistakably to a rational treatment of convulsive diseases by means of medicines whose actions it is possible to understand.

## Correspondence.

### GRATUITOUS MEDICAL SERVICES.

SIR,—Though I have read with interest the papers that have from time to time appeared in our JOURNAL on the subject of Gratuitous Medical Services, I must own that they have generally failed to approach the subject in the right direction; and that consequently, their influence on public opinion is productive of nothing more than a placid assent to the unquestionable and just conclusions of the writers. But this is not what the profession requires. We consider that our kindness and forbearance are abused, and that the system of gratuitous medical services has grown into one of the most monstrous anomalies of our times. We have allowed the axiom that "the labourer is worthy of his meat" to be ignored, and are now suffering the consequence of our own indiscretion and apathy. We, who are on the working staff of public hospitals, feel that we are at the same time doing injury to ourselves as a profession, by affording gratuitous relief to thousands who ought to be ashamed to appear in our hospitals, and misapplying public bounty to the loss—yea the robbery—of the poor. Most who have undertaken the honourable but cheerless task of ministering their profession under the Poor-law, feel how inadequate is the consideration that they receive for the endless labour and sacrifice demanded of them.

But all this is freely admitted by a discerning public, that only contemns an indifference to our just rights as a profession; while we confess, by our actions as well as by our words, that we have neither courage nor confidence in ourselves, sufficient to enable us to claim and assert our own.

What then can come of our grievances, and of our demonstrations of right, so long as we are content to grumble as individuals, and still bear our burdens; while as a body we quietly leave our case to time, and any re-

former of abuses who has leisure and inclination to help those who will not help themselves?

We waste our energies in persuading the public that our onerous duties in its service claim some adequate and proportionate subsidy, so long as we are not true to ourselves, and unite to demand it.

Think we that they will be paid for their services who are contented to work for nothing, or are too indifferent to ask for wages? No! we are not united enough to be true to ourselves, and so, as we have ever been defrauded, we must be till as a body we cooperate to resist imposition.

The time surely has come for us to demand that the managers of hospitals shall no longer require us to administer our alms, as well as theirs, to recipients of public bounty, adorned in velvet mantles, hats and feathers, and bespangled with gold chains, and earrings. It is time that the hypocrisy of well-to-do tradesmen and their families, who elbow out our poor patients, and indigent, under the mean guise of seeking "the best advice" at our hospitals, cheat us of what we are expected to give to those who cannot otherwise have our help, be exposed. It is time that our Poor-law Medical Officers should be paid as well as "the leech" who drenches or administers a bolus to an old or infirm quadruped. Instead of the pittance which barely pays "the bar," and which Tony would decline for running an errand a-foot.

Then let the profession awake to a just sense of what is due to its members; let it determine to dispense its gratuitous services to those only who would ask advice gratis of a lawyer; the poor will never ask in vain of the neediest of us; let it no longer tolerate gratuitous advice to Life Insurance Offices, that are mean enough to pay commission to agents, but ask us for information on which thousands of pounds are risked, or not risked, and we are unpaid; let it maintain the right of its members to live by the exercise of its various functions, for assuredly there is little fear of people wasting all their substance on physicians now-a-days; let its members rally round one who, in seeking to sustain the status of the profession, has to bear persecution or loss; and, lastly, let the scandal that we are ever ready to supplant one another and take advantage of a brother practitioner's difficulties, cease from among us; let it be remembered that where one suffers, all suffer, and that the honour of one is the honour of all.

I am, etc., F.R.C.S.

February 1863.

#### RUSSELL v. ADAMS.

##### LETTER FROM F. C. V. PIKE, ESQ.

SIR,—Certain statements having appeared in some of the medical journals in reference to the late action of Russell v. Adams, to the effect that I was professionally engaged and my costs paid by Mr. Propert, I beg to state most unequivocally that my services were engaged by Miss Russell and her mother, with the latter of whom I had become professionally acquainted upwards of eighteen years previously.

The action of Russell v. Adams was commenced so far back as November 21st, 1861. It was not, however, until after incessant solicitations by Miss Russell and her mother that I, with the consent of Miss Russell's then attorney, assented on January 22nd in the present year to become the attorney for the plaintiff in that action.

I have not, directly or indirectly, received, nor do I expect to receive, any portion of my costs in such action from Mr. Propert; and I may add that I had no communication whatever with Mr. Propert with reference to my undertaking the prosecution of the action on behalf of Miss Russell.

I am, etc.,

F. C. V. PIKE.

6, Serle Street, Lincoln's Inn, March 4th, 1863.

#### PREFERMENT BY AFFECTION.

SIR,—In a recent number of the BRITISH MEDICAL JOURNAL, you did me the favour to insert a letter in reference to the appointment of a non-resident, recently qualified gentleman as certifying surgeon at Oldham. As I have reason to believe the subsequent proceedings of the medical practitioners here have been watched with considerable interest and anxiety by our brethren in other towns where similar appointments are in the gift of the inspectors of factories, I ask your indulgence whilst I give your readers, either as a guide or a warning, the concluding chapter of this disgraceful episode.

At a numerously attended meeting of the medical profession resident in this town and neighbourhood, it was unanimously resolved that a deputation should wait upon the Home Secretary, for the purpose of laying before him the whole circumstances of the case, and of urging him, on the grounds of equity, to revoke the appointment. A memorial to the Town Council of Oldham was also signed by every medical practitioner in this borough, except by the gentleman who holds the corresponding appointment to the one in question, bringing the matter prominently before them. This appeal, to the honour of the Council be it told, was most heartily responded to. Not only was our memorial favourably received, but, by every gentleman who spoke, the appointment was severely animadverted upon; and the Council unanimously adopted, on public grounds, the following memorial; and resolved that J. M. Cobbett, Esq., and J. T. Hibbert, Esq., the members of Parliament for the borough, should be requested to present it.

"To the Right Hon. Sir George Grey, Bart., Her Majesty's Secretary of State for the Home Department.

"The memorial of the mayor, aldermen, and burgesses of the borough of Oldham, in the county palatine of Lancaster, in council assembled, under the common seal,

"Sheweth,—That this Council views with much dissatisfaction and regret the recent appointment made by Alexander Redgrave, Esq., of Mr. Robert William Coles, jun., to the office of certifying surgeon to the factories, lately held by Mr. Earnshaw, inasmuch as there are numerous resident practitioners in the borough of standing and experience, eminently qualified to serve the office.

"That it is manifestly unjust to the whole profession resident and practising in the borough, that their claims and qualifications should be overlooked in favour of a young gentleman entirely unknown to the public, non-resident, and only recently qualified; and your memorialists humbly pray that you will revoke the appointment of Mr. Coles, and give directions that the same be conferred on some resident medical practitioner."

This memorial was accordingly presented; and a deputation, consisting of Messrs. Abraham Leach, A. Thom Thomson, and Dr. S. H. Armitage, accompanied by the members for Oldham, afterwards had an interview with Sir G. Grey at the Home Office. They were courteously received and attentively listened to; but were given to understand that, unless they could advance some legal or moral objection, he (Sir G. Grey) did not think he could interfere with Mr. Redgrave's nomination. The only legal ground the deputation were prepared to urge, and they had authority for thinking it fatal to the appointment, was this: that the Act of Parliament (7 and 8 Vict., c. 15) provides that the person receiving the appointment shall be practising medicine or surgery; and that, as Mr. Coles was only acting as an assistant to another surgeon in a neighbouring town, he could not be considered to be practising within the meaning of the Act. This point Sir George Grey reserved for consideration, and promised an early decision. That decision has now reached us, and, as we anticipated, is unfavour-

able. Avoiding altogether the question of justice or equity, he merely, through his secretary, states that, having referred the complaint of the appointment of Mr. Coles, jun., to Mr. Redgrave, the inspector, and having received his reply, he (Sir G. Grey) does not think there are any grounds which would justify him in revoking the appointment which the inspector was authorised by law to make, and which could only be properly revoked by him, on clear evidence of some legal or moral disqualification, of which he considers there does not appear to be any proof in the present case.

So end our efforts—not altogether futile, let me hope, in this, the *first* clear case of nepotism in the patronage of these factory appointments. It is to be hoped it may not form a precedent.

Hitherto, we have had reason to boast that the rank weeds of nepotism have found no congenial soil in our profession. More favoured in this respect than our clerical sister, patronage in life and limb has been held too sacred a trust to be lightly exercised; and the relative or friend has had to find his natural level in the hard race for public preferment. So much the more is it our duty, jealously to watch for and expose any deviation from the strict path of rectitude, where a public trust is in question.

In almost all the manufacturing towns, where the position of certifying surgeon is within the reach of the profession, the great bulk of the population necessarily consists of the working classes. In such towns, however high a reputation a medical man may attain, he finds it necessary to build up his practice with such material as exists around him. There are no aristocratic or select practices, by which a competency may be realised from a comparatively limited number of patients; but, as a rule, the work is heavy and the remuneration light. Physical and mental toil soon tell their story; \* “the snow appears early on the mountains”; and the appointments connected with the factories—the only appointments of value in these districts, and arising, as it were of necessity, out of the very evils from which we suffer—are looked forward to as a haven, after the heat and burden of the day.

If patronage is to be exercised, as it has been by Mr. Redgrave in the case at Oldham, a serious question must sooner or later arise between our profession and the civil service. Subordinate officers will educate their sons with a certainty of preferment; the workshop and the foundry will give up their youth; some complaisant member of our profession, holding, or *expecting* to hold, a factory appointment, may be found willing to accept them as pupils without a fee; and a gross professional wrong, maturing for years, may find its consummation so soon as the fortunate neophyte has crossed the portals of the medical profession. It behoves all of us, therefore, to watch narrowly subsequent nominations emanating from the same quarter. The whole tribe of incompetent mediocrities and subservient hangers-on may in this instance sing a psalm over our failure; but, if any future Redgrave or Coles, trusting to this as a precedent, should contemplate the perpetration of a similar injustice, there shall at least be found on record the indignant protest of an outraged profession.

I am, etc., BETA.

Oldham, March 2nd, 1863.

\* In the town of Oldham, the mortality amongst medical men has been perfectly appalling. Only three of those practising eleven years ago are now alive. During that period twelve have died: nine of these died before attaining the age of 46 years; and nine, either primarily or secondarily of brain-disease.

## Medical News.

APOTHECARIES' HALL. On February 26th, the following Licentiates were admitted:—

Armstrong, James Hunter, Gravesend  
Nash, George Branstons Valentine, Royal Infirmary, Liverpool  
Slade, Robert, Poole, Dorset

At the same Court, the following passed the first examination:—

Wicksteed, Frank William Slow, St. Bartholomew's Hospital

### APPOINTMENTS.

Biggs, Robert, Esq., appointed Deputy Coroner for North Somersetshire.

Hogg, Jabez, Esq., appointed Surgeon-Oculist to the Royal Masonic Schools.

\*PRIESTLEY, William O., M.D., elected Professor of Midwifery in King's College, in the room of Arthur Farre, M.D., resigned.

SANDERSON, John B., M.D., appointed Assistant-Physician to the Middlesex Hospital.

THOMSON, John, Esq., appointed Certifying Surgeon under the Factory Act, for the district of Kilmarnock.

COLEMAN, Alfred, Esq.

FOESYTH, Frederick, Esq.

GREGGON, George, Esq.

\*HAYWARD, Henry H., Esq.

HILL, Alfred, Esq.

WALKER, Joseph, M.D.

} Appointed Assist. Dental Surgeons  
to the Dental Hospital of London.

### POOR-LAW MEDICAL SERVICE.

CREAN, Thomas J., L.K.Q.C.P.I., to be Medical Officer to the Marlfield District of the Clonmel Union.

FITZGIBBON, Patrick, L.K.Q.C.P.I., to be Medical Officer to the Clonmel District of the Clonmel Union.

KNILL, James, L.R.C.P.Ed., to be Medical Officer to the Nettlebed District of the Henley Union.

### ARMY.

ANDREWS, Staff-Assistant-Surgeon R. F., to be Staff-Surgeon, *vice* W. Snell.

GALBRAITH, Surgeon-Major G. T., M.D., 53rd Foot, to be Staff-Surgeon-Major, *vice* R. McNab, M.D.

M McNAB, Staff-Surgeon R., M.D., to be Surgeon 53rd Foot, *vice* G. T. Galbraith, M.D.

RUTHERFORD, Surgeon C. C., 99th Foot, to be Staff-Surgeon, *vice* U. W. Evans, M.D.

SNELL, Staff-Surgeon W., to be Surgeon 99th Foot, *vice* C. C. Rutherford.

To be Staff-Assistant-Surgeon:—

HAMILTON, Assistant-Surgeon J. B., 3rd West India Regiment.

VOLUNTEERS. (A.V.=Artillery Volunteers; R.V.=Rifle Volunteers):—

POCOCK, C. J., Esq., to be Assistant-Surgeon 1st Sussex A.V.

### BIRTH.

FLETCHER. On March 1st, at Manchester, the wife of \*J. Ogden Fletcher, M.D., of a daughter.

### DEATHS.

BORLAND, James, M.D., Inspector-General of Army Hospitals, at Teddington, aged 88, on February 22.

BOYCE, William, M.D., at Edinburgh, on March 1.

CAMPBELL, John, M.D., Surgeon R.N., aged 69, at Southsea, on February 24.

HESTER. On December 2nd, 1862, at New Orleans, Jeffreson, third son of \*James T. Hester, Esq., of Oxford.

HUTCHINSON. On March 2nd, at Scarborough, aged 52, Jane Innes, wife of R. S. Hutchinson, M.D.

\*MCNICOLL, Thos., Esq., Surgeon, at Liverpool, aged 41, on March 1.

SERCOMBE. On March 2nd, at Bournemouth, aged 3, Annie E., third child of \*Edwin Sercombe, Esq., of Brook Street.

STUART, John Graham, M.D., H.E.I.C.S., at Edinburgh, aged 65, on March 2.

WILLIS. On March 2nd, at Barnes, Eleanor, wife of \*Robert Willis, M.D.

BEQUESTS. The late Marquis of Lansdowne has left by will to Lord Montagu and the governors of Barrington's Hospital, in Limerick, the sum of £3,000, to be expended by them for the benefit of said hospital, provided that it shall be open at all times for the natives of the county of Kerry. The late Mr. William Block, of Muswell Hill, has left £500 to the Royal London Ophthalmic Hospital.

DR. GUGGENBUHL. The death of the famed physician of the Abendberg in Switzerland, the manager of a cretin establishment there, is announced. If report speak truly, his philanthropy has not interfered with his amassing of much money.

**BIRTHS AND DEATHS REGISTRATION (IRELAND) BILL.** This bill has been read a third time and passed in the House of Commons.

**UNIVERSITY OF OXFORD.** In a convocation holden on the 26th ult., a proposal that the sum of £1,000 be granted from the university chest towards the new buildings at the Radcliffe Infirmary was agreed to.

**SOUTH HANTS MEDICO-CHIRURGICAL SOCIETY.** The following officers have been appointed for the ensuing year:—*President*, John S. Bushnan, M.D.; *Vice-President*, John Wiblin, L.R.C.P.Ed.; *Secretary*, Henry Palk, M.D.

**ARMY HOSPITALS.** The entire staff connected with the Royal Artillery and Royal Engineer hospitals at Brompton Barracks, Chatham, together with the patients and attendants, vacated the hospitals on Saturday afternoon and took possession of Fort Pitt Hospital, which will in future be used as a general hospital for the entire garrison, on the removal of the Army Medical School and staff to Netley Hospital. A portion of the hospital hitherto used at Brompton barracks is still to be retained for the purposes of a hospital, in which the sick troops will be received and inspected previous to their removal to Fort Pitt.

**THE LEVÉE.** The following are the presentations of members of the medical profession which took place last week:—Mr. J. Moncrieff Arnott; Assistant-Surgeon Agnis; Surgeon H. Baillie; Dr. Butler; Mr. William Bowman; Mr. William Coulson; Assistant-Surgeon J. C. Corbyn; Sir Daniel Cooper; Dr. Acland; Dr. A. Anderson; Dr. T. K. Chambers; Staff-Surgeon-Major Dr. W. Dick; C. F. Du Pasquier; Surgeon W. C. B. Eatwell; Dr. C. J. Foster; Surgeon R. Gilborne; Dr. Gallagher; Surgeon-Major A. Grant; Dr. Francis Hawkins; Mr. C. H. Hawkins; Dr. E. Hilditch; Surgeon-Major Jee; Dr. W. Jenner; Dr. R. O'Shaughnessy; Dr. G. E. Paget; Mr. James Paget; Dr. E. Phillips; Mr. George Pollock; Mr. R. Quain; Surgeon H. Martin; Dr. G. C. Millar; Dr. J. M. Minter; Dr. Sieveking; Deputy Inspector-General C. J. Smith; Dr. G. Sykes; Assistant-Surgeon R. Turner; Assistant-Surgeon E. J. Vivian; Dr. Forbes Watson; Dr. J. Grant Wilson; Surgeon Young, and Surgeon-Major Wyatt.

#### OPERATION DAYS AT THE HOSPITALS.

**MONDAY.....** Royal Free, 2 P.M.—Metropolitan Free, 2 P.M.—St. Mark's for Fistula and other Diseases of the Rectum, 1.15 P.M.—Samaritan, 2.30 P.M.—Lock, Clinical Demonstration and Operations, 1 P.M.

**TUESDAY....** Guy's, 1½ P.M.—Westminster, 2 P.M.

**WEDNESDAY....** St. Mary's, 1 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.

**THURSDAY.....** St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—London, 1.30 P.M.—Great Northern, 2 P.M.—London Surgical Home, 2 P.M.—Royal Orthopædic, 2 P.M.

**FRIDAY.....** Westminster Ophthalmic, 1.30 P.M.

**SATURDAY.....** St. Thomas's, 1 P.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.

#### MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**MONDAY.** Medical Society of London, 8.30 P.M. Clinical Discussion. Dr. Thudichum. "On Cancer of the Pancreas; and on Purulent Disease of the Kidney, complicated with Disease of the Bladder;" and other communications.—Royal Geographical.

**WEDNESDAY.** Royal College of Physicians, 5 P.M. Dr. Risdon Bennett. Croonian Lectures. "On some Points connected with Bronchitis, and its Results."—Society of Arts.—Microscopical.—North London Medical.

**THURSDAY.** Royal.—Antiquarian.

**FRIDAY.** Royal College of Physicians, 5 P.M. Dr. Chambers. Lumen Lectures. "Formation of Mucus and Pus."—Astronomical.—Royal Institution.

**SATURDAY.** Statistical (Anniversary).—Royal Botanical.

#### TO CORRESPONDENTS.

.\*. All letters and communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen St., Lincoln's Inn Fields, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

**MEDICAL HEALTH ASSURANCE.**—We are obliged to defer the publication of some letters on this subject till next week.

**UNLICENSED PRACTITIONERS.**—We would refer "An Old Associate" to something we have said in this day's JOURNAL on the subject of irregular practitioners. It does appear that in the present state of the law, any man, woman, or child, can practise medicine or surgery, if they can only find subjects to practise on. We see no way to arrest the course of the irregular person to whom our correspondent refers. This, however, we would add: that any practitioner of medicine who knowingly meets an unlicensed man in consultation is utterly without excuse, and deserves the severest condemnation of the profession. The laxer the law is, the more severe ought our ethical laws to be. We hope our correspondent is in error when he says that the person to whom he refers "is met in consultation by physicians of high repute, and yet withal is unlicensed, unregistered, and laughs in his sleeve at the medical profession".

COMMUNICATIONS have been received from:—Mr. J. Vose Solomon; Mr. Thorley; Mr. H. GRAMSHAW; AN ARMY MEDICAL OFFICER; Dr. CROMPTON; Dr. C. KIDD; Dr. J. O. FLETCHER; AN OLD ASSOCIATE; Mr. T. P. DAVIES; THE HONORARY SECRETARY OF THE WESTERN MEDICAL AND SURGICAL SOCIETY; Dr. LIONEL BEALE; Dr. SIEVEKING; Mr. CARTER; Dr. BRYAN; Dr. THOMAS J. WALKER; Mr. R. W. COE; Dr. J. HEYGATE; BETA; Dr. HENRY MARSHALL; Mr. J. A. PEARSON; Mr. RADCLIFFE; THE REGISTRAR OF THE MEDICAL SOCIETY OF LONDON; Dr. OGLE; Mr. PIKE; Mr. J. H. S. MAY; and Mr. T. M. STONE.

#### ADVERTISEMENTS.

### Great Saving in the Purchase

of NEW MEDICAL GLASS BOTTLES and PHIALS, at the NORTH LONDON GLASS BOTTLE WORKS—I. ISAACS and COMPANY (Proprietors). London Warehouse, 24 and 25, Francis Street, Tottenham Court Road, W.C.

6 & 8 oz., any shape, plain or graduated	Clear	{ 8s. 0d. per gross.
3 & 4 oz. ditto	blue-tinted	{ 7s. 6d. "
½ oz. Moulded Phials		{ 4s. 6d. "
1 oz. ditto		{ 5s. 6d. "
1½ oz. ditto		{ 6s. 0d. "
2 oz. ditto		{ 7s. 0d. "

Of a very superior quality.

A remittance not required till the goods are received. Packages free. Immediate attention to Country orders. Goods delivered free within 7 miles. Post-office Orders payable to I. ISAACS and CO., at the Post Office, Tottenham Court Road. Bankers—Unity Bank Western Branch.—Established upwards of 70 years.

**NOTICE.**—ISAACS & CO. beg to inform the Medical Profession that in order to oblige those gentlemen who favour us with their commands, they have established an Express Department, by which all urgent orders will be dispatched the morning received. All letters marked X on the envelope will have priority.

### For Varicose Veins and Weak-

NESS. Very superior SURGICAL ELASTIC STOCKINGS and KNEE-CAPS, on a New Principle, pervious, light in texture, and inexpensive, yielding an efficient and unvarying support, under any temperature, without the trouble of Lacing or Bandaging. Likewise, a strong low-priced article for Hospitals and the Working-classes.

**ABDOMINAL SUPPORTING BELTS** for both Sexes, those for Ladies' use, before and after accouchement, are admirably adapted for giving adequate support with EXTREME LIGHTNESS—a point little attended to in the comparatively clumsy contrivances and fabrics hitherto employed.

Instructions for measurement and prices on application, and the articles sent by post from the

Manufacturers

POPE and PLANTE, 4, Waterloo Place, Pall Mall, London. The Profession, Trade, and Hospitals supplied.

# The London Medical Review

(enlarged eight pages) for March

CONTAINS:—

ORIGINAL ARTICLES.

1. Dr. Tanner, "On Cancer of the Female Sexual Organs."
2. Dr. Inman, "Essays on Therapeutics."
3. Thomas Orton, M.R.C.S., "On Poisoning by Arsenical Paper-hangings."
4. Dr. Houghton, "On the Science of Medicine."
- ANALYTICAL AND CRITICAL REVIEWS.
5. "Diseases of the Chest." By Henry Wm. Fuller, M.D. Cantab., etc.
6. "The Renewal of Life: Clinical Lectures, illustrative of a Restorative System of Medicine, given at St. Mary's Hospital." By Thos. K. Chambers, M.D., F.R.C.P.
7. "On Diminishing the Danger of Corneal Suppuration in the Extraction of Cataract." By Dr. Albert Morren of Crefeld.
8. Short Notes on Books Recently Published.
9. A Retrospect of the Progress of Medical Science at Home and Abroad.

Price One Shilling. Annual Subscription, 13s. Post Free.

TREASURER—Robert Dunn, Esq.

BANKERS—Messrs. Gosling and Sharpe, 19, Fleet Street.

SECRETARY—John Capes, Esq.

The objects of this Society are—

1st. To provide a safe and efficient medium by which the Medical Profession may secure more certain and regular payment for their services: with every consideration for the convenience of those who are willing, but unable directly to discharge their liabilities; with rigour from those who are able but have not the disposition to remunerate medical men.

These ends are to be accomplished without interfering with the valuable time of the Members of the Profession, or exposing them to the unpleasantness which necessarily attends applications for money, or to the uncertainty and risk of employing private collectors.

2nd. To assist Members with information and advice in the purchase and sale of Practices.

3rd. To raise a Benevolent Fund by devoting to that object the profits arising from the general operations of the Society.

The Society consists of qualified Medical Practitioners *only*. Annual Subscription, One Guinea; a Firm, consisting of two Partners, a Guinea and a half; a Firm of three Partners, Two Guineas. Fixed rates of Commission are also charged on business transacted.

The general business is carried on by a staff of officers at the Central Office, 43, Lincoln's Inn Fields, together with trustworthy employes appointed in town and country, the whole of whom are under the direction and superintendence of the Committee.

The Metropolitan Members of the Committee, with the Trustees, are responsible for all moneys received by the staff.

# Royal Medical Benevolent Col-

LEGE, EPSOM.—Notice is hereby given, that no applications on behalf of persons desirous to become candidates for admission to the College as PENSIONERS or FOUNDATION SCHOLARS at the next ensuing Election can be received by the Council after the Morning of the 16th of March inst., when the list of candidates will be finally closed, in order that the Balloting Papers may be printed. The Election will take place, as usual, in May.

By order of the Council,

ROBERT FREEMAN, Secretary.

Office, 57, Soho Square, London, March 4, 1863.

# Royal Medical Benevolent Col-

LEGE.—The Council have the pleasure to announce that the Right Hon. the EARL MANYERS has kindly consented to take the Chair at the ELEVENTH ANNUAL FESTIVAL of the College, which will take place at Willis's Rooms, King Street, St. James's, on Wednesday, the 29th of April next, when it is earnestly hoped that there will be a large meeting of the friends of the Institution.

The following Gentlemen have already undertaken to officiate as Stewards on the occasion, and a further list will be published shortly. Gentlemen who are willing to serve are requested to forward their names to the Treasurer, JOHN PROPERT, Esq., 6, New Cavendish Street, W. There is no liability attached to the office.

## Remarks

ON

### DR. BEALE'S CLINICAL LECTURE ON "THE RENEWAL OF LIFE".\*

BY

THOMAS KING CHAMBERS, M.D.,

HONORARY PHYSICIAN TO H.R.H. THE PRINCE  
OF WALES; ETC.

WHEN a professor at King's College deems certain opinions of sufficient influence for him to give a clinical lecture on the subject, warning his pupils against them, I think he may fairly claim a considerate reply.

The professor tells his class that *The Renewal of Life* gives an unfair representation of the doctrine of counterirritation, when it states that "the idea of counterirritant practice is to substitute one *disease* which is less dangerous and painful, or whose disorganising tendencies are but temporary, for another *disease* which may be dangerous or painful, or which tends to disorganise the body." His italics point his objection to this use of the word *disease*, which he says is not applicable to purgation and excessive diuresis. He has hit upon this as the fallacy which affects my argument.

Now, it is a well-known and an honest rule with controversial writers (among whom I suppose I must be classed in the introductory lecture above quoted), when stating the doctrines which they impugn, to take the wording from the best upholders of such doctrine. This rule I was careful to observe in the instance before us; my description of counterirritation is that given by Dr. Pereira, who calls it "the production of an artificial or secondary *disease* in order to relieve another or primary one." Again, he says, "one *disease*, whether artificially or spontaneously generated, will often, but not invariably, supersede another." (Pereira's *Materia Medica*, vol. i, part i, chap. 9.) I am not quoting Dr. Pereira as an authority in lieu of argument, but as an authoritative historian. Dr. Pereira saw clearly enough, as did also Dr. Parry and Dr. Pring, whose opinions he is elucidating, that every state of body which is not health is disease. It is quite indifferent to the pathologist, when investigating peculiar states in question, whether they are produced by a physician's drug, or a felon's poison, or an epidemic malaria, climatic influences, or organic changes in the patient's body. No progress in pathology can be made till this is clearly understood. And, what is of more importance, we should be very bad practitioners if we did not act upon it. In how large a proportion of our patients can that for which we prescribe be described by the nomenclature of the Registrar-General or any other nosologist? In half?

In one of Miss Young's delicate sketches of character, a strong-minded and strong-limbed young lady is described as having "no sympathy with unclassified diseases." She could pity a case of apo-

plexy or measles; but being "out of health" or "ill" found no favour in her sight. I fear the learned professor has a tendency towards the same condition of mind; for he further objects to my saying that drugs "make a sound man *ill*." Has he never heard of people being "ill of the doctor"?

He further says that it is dangerous to try and draw a line between healthy and diseased states. Yet he himself draws one; "ascertain," he says, "with accuracy what is going on, and contrast it with what physiology teaches us *ought* to go on." The latter is health; the former, if it differs, is disease; as I have taught, only in fewer words. This test will certainly include the operation of purgatives and diuretics as diseased actions.

Dr. Beale's next objection is a most serious one, and I am anxious to draw special attention to it, because it touches the real point my little volume was designed to raise. The clinical lectures there reprinted are put together with a view of illustrating, by bedside teaching, my proposition that all disease is best treated as a deficiency of life, as a degeneration from complete vital functions, and that all our most trusted remedial agents are beneficial, directly or indirectly, by restoring life. I grant that the proposition is a novel one, and that Dr. Beale is right, as a teacher, to look at it with suspicion. He is right, too, from the position he occupies, not to flood the question with quotations from authorities; but to handle it manfully and boldly himself. He upholds the converse proposition; viz., that disease may "consist of an excess of action"; that a diseased tissue may "exhibit greater evidence of vital activity than the same bulk of healthy tissue"; and, of course, he goes on to infer that the aim and intention of a physician should often be "to weaken life," though he does not go quite so far as Van Swieten's statement that this is all our art can do. He gives, as his instances, cancer and purulent or fibrinous pneumonia; so that I had better take them, as they doubtless tell more for his propositions than any others which could be given.

The fact that diseased parts are often increased in solid bulk is of serious import, and suggests two questions, both of very practical bearing:—

1. Does augmented bulk imply augmented general life in the individual?

2. Does it imply augmented local life in the part affected?

To the first question, a sufficient answer may be found in any of the medical or surgical wards of a hospital. It is not the burly, full-pulsed, red blooded man of large appetite and great muscular power that is most likely to exhibit a specimen of solid morbid matter, but the starved anæmic, quivering at a breeze or a blow.

In what corpse do you find the greatest weight of fibrine thrown out in the peritoneum in the shortest possible time? In one dead of puerperal fever—that is, in the weakest sex at the period of its greatest weakness.

In whom is rheumatic fever most likely to cause pericarditis, with its great masses of morbid matter? In the young overgrown person, especially if a female, more especially if an overworked, underfed maid-of-all-work, and still more especially if vital power is lowered (as M. Edwards has shown it to be) by cold.

\* See BRITISH MEDICAL JOURNAL, February 21st, 1863.

In whose heart do the consequences of this pericarditis most rapidly induce enlargement? Not in the well-fed and well-clothed; but at the same weakly time, in the same weakly sex, and under the same debilitating circumstances as the original lesion occurred.

Cancers and other tumours are found of quickest growth and most frequently in the least lively bodies, in the least lively parts, in the idle uterus, in the unused breast, in the cellular tissue, in scars, in parts half killed by wounds, injuries, or previous disease.

Take now the second question, and let us concede the possibility, that, while the general vitality of the individual is lessened, some part might exhibit an extra amount. But morbid processes are not evidences of it; they rather resemble developments of a lower form of life; their products, though abundant, are less vital than the normal growth whose place they take; their existence is temporary, and "they are not capable of becoming permanent constituents of the body, or of lasting as long as the individual." (Virchow's *Cellular Pathology*, p. 456.) Examine a patient with thickened heart during life, and the pulse does not strike your finger vigorously, the apex of the organ does not beat sharply against the ribs; indeed, the thicker it becomes, the less powerful is both pulse and beat, and the less actively does the blood course through the vessels. Examine it after death, and you will seldom fail to find a pale tissue with microscopical evidences of commencing fatty degeneration. Still more evident is the same degenerative tendency in cancer. The tissue of malignant tumours, directly it ceases to grow rapidly, begins to decay, to shrink, and be converted into fat. It is difficult to imagine local strength or local excess of life producing such a weakling crop.

In cancer, truly, there is a continuous reproduction of new foci of growth, a new progeny of prolific cells, which certainly does look like an extension of local life over a larger space, if not of the production of fresh local life. But when we should reflect that the highest and most vital function of nutritive growth is the retention of the form of the body or its separate parts; that in morbid augmentations of size this is lost; the regulating and forming power is absent, and the more so the more morbid and the larger the augmentation is.

The formlessness of cancers and of so-called hypertrophic tissues refers them to a lower grade of organic life than normal growth.

Size proves nothing; surely the professor would not maintain that there is more vitality in a jelly-fish than in a sprat, in a mushroom than in a flea.

This is not a mere question of verbal criticism or Sorbonnic controversy; it is a matter of life and death to our patients. If we treat cases of pneumonic consolidation by weakening life, by bleeding *coup sur coup*, by antimony, by starvation, we are doing our best to kill them; if we supply life by food, warmth, moisture, etc., we are doing our best to save them. If Dr. Beale tries to "weaken the life of a cancer" in the same way, it will grow all the quicker; if he will give the patient tonics, food, oil, and other restoratives, it is much more likely to become dormant.

Dr. Beale says that "few will agree" with me. He should not have used the future tense; for I fully

expect that soon not only all the class he was addressing, but the professor himself, will cordially agree with the theses he has made me responsible for. They must daily become more and more the guide to medical practice, and I should be glad to see them in the hands of teachers more influential than myself. In the meantime, I do not think he ought to have objected that they are "not supported by observations"; for I have done my best by illustrations from the patients at the time under the eyes of my pupils, and have appended twenty-seven lectures thus illustrated to the Introductory on which he comments.

## Short Clinical Lectures

ON

## THE FIRST PRINCIPLES OF MEDICINE.

Delivered at King's College Hospital.

BY

LIONEL S. BEALE, M.B., F.R.S.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS; PROFESSOR OF PHYSIOLOGY AND OF GENERAL AND MORBID ANATOMY IN KING'S COLLEGE, LONDON; PHYSICIAN TO KING'S COLLEGE HOSPITAL; HONORARY FELLOW OF KING'S COLLEGE; ETC.

### II.

#### ON THE VITAL CHANGES OCCURRING IN THE MUCUS-CORPUSCLE.

IN my last lecture, I was compelled to speak of *living cells*, changes occurring during *life*, *vital* phenomena, etc. It is right, therefore, that I should endeavour to explain what I mean by a *living cell*. I ought to tell you what goes on in a living cell, and how this living cell gives rise to other living cells. As long as our views upon these fundamental questions remain unsettled, we shall be unable to give an intelligible account of the simplest changes occurring in the very simplest structures in health or disease.

The words *life*, *vitality*, *vital* power, are used so vaguely and so carelessly in speaking of a patient's state, that it is my duty to attempt, at least, to describe to you what meaning I attach to them. Moreover, these terms have been used in very different senses. They have been applied to the organism as a whole, as well as to the separate elementary parts or cells of which the tissues are composed. Our life may be destroyed, but many of our tissues may exhibit vital actions for some time afterwards. Many of our tissues live longer than we ourselves live. In this lecture I restrict myself to the consideration of the *vital* changes which take place in individual "cells."

I have shown that a cell always consists of *living matter*, and matter that *has lived* (of germinal matter and formed matter), and that no structure exists *which is composed entirely of living matter*.

It is true that, in the present state of knowledge, we cannot explain how some of the simplest phy-

siological changes which occur in the body in health take place. Nor have we much positive knowledge even of the actual phenomena which occur in some of those states, which, though scarcely to be called morbid, nevertheless can be distinguished from those characteristic of health. For example, how ignorant are we of the precise order of the occurrence, and of the exact relation to each other, of the changes which take place in the course of a common cold. We do not know how the very unpleasant chilly sensation which marks its accession is produced; neither are we acquainted with the condition of the blood which precedes and is undoubtedly connected with the dry congested state of the mucous membrane; nor are the precise causes of the increased secretion which soon takes place from the nasal or bronchial mucous surface accurately determined.

If, however, the changes which occur upon the surface of the mucous membrane be carefully watched, many highly important facts which have no slight bearing upon the question of the nature of vital changes generally, will be revealed. And we can actually demonstrate the transition from normal structure of a very simple kind, to what is spoken of as a morbid product.

Every one knows that upon the surface of the mucous membrane of the air-passages, even in health, there is a small quantity of a soft viscid matter generally termed *mucus*. This mucus, said to be secreted by the mucous membrane, contains certain oval or spherical cells or corpuscles, which are transparent and granular. From the change of form which takes place in them, it is certain that the matter of which they are composed is almost diffident. These corpuscles or cells are *mucous corpuscles*. They have no cell-wall. They are embedded in, and separated from each other by, a more or less transparent, viscid, tenacious substance termed *mucus*. This viscid mucus bears to the corpuscles the same relation that the matrix of cartilage bears to the so-called cells, or the fibrous tissue of tendon to its "nuclei," and it is considered by many to be an *intercellular substance*.

The specific character of the mucus depends upon the presence of a peculiar substance called *mucin*, which exhibits certain well-known chemical characters. Now, neither mucus nor mucin can be made from albumen or any other constituent of the blood, lymph, or chyle; nor does it exist ready-formed in those fluids; nor can it be prepared artificially. What is, then, the origin of this peculiar substance characteristic of mucus? Its elements must be, directly or indirectly, derived from the blood. It never exists without the corpuscles, and when it increases in quantity the corpuscles are found in increased number. There is, therefore, reason to infer that the formation of the mucus is in some way connected with the presence of the corpuscles. You may have masses of germinal matter without the tenacious mucus; but you cannot have mucus without the masses of germinal matter being present at the time of its formation. This fact has never yet been explained by those who still maintain that the so-called intercellular substance is formed by changes taking place in an exuded plasma independently of nuclei or cells (germinal matter).

Moreover, it is important to observe that the chemical characters and physical properties of the

mucus are not dependent upon the life of the corpuscles. The germinal matter of the mucus-corpuscles may be living and active, or dead and even disintegrated, without any observable immediate change upon the viscid mucus, so that it would appear that the mucus-corpuscles exert no direct influence upon the mucus *after its formation*.

Mucus, which is formed in health in very small quantity, is produced more rapidly and in larger amount in a slight cold or catarrh; but it still retains its transparency. If, however, the catarrhal state increase in severity, the mucus becomes more opaque. It is formed still faster, so that in the course of an hour more than a thousand times as much material, possessing definite chemical characters, may be produced upon the surface of the membrane, as is formed by it in the perfectly healthy state, which existed perhaps but two or three days previously. Examination will show that the opacity is due to the increased number of the granular corpuscles it contains, just as the creamlike appearance of laudable pus depends upon the multitude of corpuscles suspended in the fluid.

If you examine a little transparent mucus from the nose or windpipe upon a warm slide immediately after its removal, and under a very high power (not less than 1200 diameters), you will observe some very important facts which bear upon the general question of *life, growth, and formation*.

You see a great many of the corpuscles I have alluded to, which vary somewhat in shape and size; but their form is generally oval, their outline even, and most are about the one-thousandth of an inch in their longest diameter. I will not discuss whether they are cells, nuclei, or corpuscles; but will call them masses of living or germinal matter, because I shall show you that they are alive and that from them new corpuscles are formed. These bodies, like pus-corpuscles, the "nuclei" of epithelial cells, and fibrous tissues, etc., are coloured by carmine.

Let us watch very carefully one of the oval masses of germinal matter under a power of 3000 diameters. It seems to be composed of soft semitransparent matter, which exhibits delicate spherical particles varying in size in every part. These particles are in constant motion, and the movements are like those so well known in the salivary corpuscles. About the central part, two or more nuclei will be observed. These appear smoother than the rest of the mass; but even in them, indications of the existence of smaller spherical particles may be discerned with a power magnifying 3000 diameters when the light is well arranged.

In a few moments, an oscillation of the particles is observed at some portion of the circumference of the mass. Then one or many bulgings occur, and parts of the circumference become quite uneven by the formation of a number of little processes which move from the general mass, and often assume the form of little spherules which still remain attached by narrow pedicles to the general mass. Such changes occur at different points of the circumference, and from time to time some of the protrusions recede into the mass. Occasionally two or more processes coalesce, and a ring may be momentarily produced at some part of the circumference.

[To be continued.]

## ST. GEORGE'S HOSPITAL.

OBSERVATIONS ON THE TREATMENT OF TÆNIA, ESPECIALLY BY THE USE OF THE OIL OF MALE-FERN.\*

By JOHN W. OGLE, M.D., F.R.C.P., Assistant-Physician to, and Lecturer on Medical Pathology at, St. George's Hospital.

At page 960 of the second volume of the *Elements of Materia Medica and Therapeutics* (3rd edition), by Dr. Pereira, that authority, speaking of the oleum filicis maris, observes as follows: "The dose is from half a drachm to a drachm, in the form of electuary, emulsion, or pills: an hour afterwards, an ounce or an ounce and a half of castor oil should be exhibited. . . . *I have tried it in several cases of tapeworm, but without effect.*"

It is with reference to the latter statement by Dr. Pereira that, seeking to add to the information which various authors have supplied on the matter, I have put together the following observations regarding certain points related to the treatment of that form of the tænia which we meet with the most commonly in England. These I am enabled to give in connexion with short

notes which I am in the habit of making of any cases amongst my hospital out-patients which may appear to offer more than ordinary interest. From what follows, it will be seen that I have generally given the oil of male-fern in doses varying from half a drachm to two drachms, considering a fair medium dose for the adult to be about a drachm and a half. In almost all cases this has been administered in combination with the acacia mixture of the *Pharmacopœia*, and in some aromatic vehicle (chiefly pimenta or peppermint-water) on a fasting stomach. This draught has been ordinarily given at bedtime, and followed up, on the following morning, by a dose of castor oil or "haustus sennæ". It will be remarked that, as Dr. Gull observed in a paper in the *Guy's Hospital Reports* (vol. i, p. 1, 1855), there is probably no absolute necessity for the dose of castor oil or senna, inasmuch as the male-fern oil is sufficient in most cases both to poison the offending worm and summarily to lead to its disposal. Its administration is, however, perhaps desirable, in order the more strictly to secure evacuation of lingering portions of the worm, if such there may be.

In the following tables, consisting of an epitome of twenty-four cases, I have not sought to give the symptoms accompanying the presence of the worms in the bowels, nor in any way to arrange the cases. I have merely, in an indiscriminate manner, recorded them with reference to the age of the patient, the length of time for which the worm was known to exist, the character of the previously used remedies, and the doses of the male-fern oil used, with the results following its administration; in this, observing the order adopted by Dr. Gull in his paper before quoted. The results of an examination of these details are given at the close of the table.

No.	Age.	Duration of symptoms; habits of life.	Former remedies used.	Dose and effect of the male fern.
1	32	Tape-worm known to have existed ten years.	Had taken turpentine as many as twenty times; and as much as twelve yards of the worm passed at a time in consequence. Had never known the head to pass.	Castor oil, 1 oz. at bed-time. In the morning, oil of male-fern, 2 drachms; acacia mixture, 3 drs.; peppermint water, 2 oz. Twelve yards of the worms passed five hours after the draught with male-fern. "Nothing unpleasant" to the patient in the action of this medicine. The worm "ran from a large thickness to quite a small point." The small part was said "by those who had seen others to be the head and tail."
2	16	Was under my care for tænia three times, on each occasion with an interval of about two years. After each visit, he failed to appear at the hospital until necessity compelled him. Not seen since last visit.		When first seen, the following draught was given:—Oil of male-fern, 2 drs.; acacia mixture, 3 drs.; peppermint water, 2 oz. Eight yards of the worm were evacuated shortly afterwards. On second visit, a similar dose: 25 yards evacuated by it. On third visit, a similar dose; but he has never been since to the hospital. No head ever brought.
3	28	Tape-worm known for eighteen months.	Had taken turpentine.	Oil of male fern, 2 drs., with acacia mixture and pimenta water at night; an ounce of castor oil in the morning. About 30 yards of tape-worm passed shortly after the castor oil, without uncomfortable effects.
4	45	Tape-worm known to have existed eighteen months.	Had been in the habit of taking every second week 3 grains of calomel at bed-time and 5 drops of turpentine in water next morning, with the effect of bringing away about from 200 to 300 pieces for the next two or three days.	Oil of male-fern, 2 drachms, in decoction of quassia, and acacia mixture at bed-time; castor oil in the morning. No worms were passed after these doses. They were therefore repeated, and then 5 yards were brought away. Two doses were subsequently given, but no more passed, though their action was abundant. No complaints as to the medicine.
5	46			Oil of male fern, 2 drachms, with acacia mixture and pimenta water at bed-time; castor oil in the morning. Large "tape-worm" brought away shortly after the draught.
6	14	Tape-worm known to have existed about eighteen months.	Passed two large tape-worms a year ago after turpentine and castor oil. Two drachms of turpentine with acacia mixture and mint water given recently, but without effect.	Oil of male-fern, 2 drachms, in mint water and acacia mixture at bed-time. A very large tape-worm was passed shortly after the fern draught. The head was looked for by the patient, but not found, "though very near it."
7	20	Tape-worm for many months, and passed three within the last six months.		Oil of male-fern, 2 drachms, in acacia mixture and pimenta water at bed-time; castor oil the next morning. "Large tape-worm" passed 12 hours after the castor oil.
8	13	Tape-worm known for two years; passed one two months ago, of eight yards in length; and another, of the same length, one week previously. Whether the head had been expelled on either of these occasions, was unknown.		Three doses of castor oil on alternate nights; and 1½ drachm of oil of male-fern in acacia mixture and pimenta water on each of the following mornings. No tape-worm passed after any of these doses.

\* Being part of a lecture delivered at St. George's Hospital.

TABLE (continued).

No.	Age.	Duration of symptoms; habits of life.	Former remedies used.	Dose and effect of the male fern.
9	21	Tape-worm known to have existed eighteen months. Not known to exist in other members of the family. Not in the habit of taking ham or bacon or sausages.	Has taken oil of turpentine on two occasions. No worm brought away by it; but "the water stopt" each time.	Oil of male-fern, $1\frac{1}{2}$ drachm, in pimenta water and acacia mixture, followed by castor oil. Ten feet of the worm evacuated after the castor oil had been taken. The draught was repeated, but no more of the worm expelled.
10	21	Tape-worm known for four months.	Taken "all sorts of medicine" without effect, including turpentine.	Half an ounce of castor oil at bed-time. Oil of male-fern, $1\frac{1}{2}$ drachm, in pimenta water and acacia mixture next morning. Several yards of the worm passed, "one end being very small indeed."
11	57	Symptoms, such as pain and gnawing at the epigastrium, voracious appetite, etc., for six months; but no tape-worm or parts seen, though suspected. No members of the family known to have it.		An ounce of castor oil at night. Oil of male-fern, 2 drachms, in pimenta water, etc., next morning. In less than four hours after the fern draught, six yards of the tape-worm were passed. Patient was "made ill all over" and "so weak and trembling" by the draught. It acted four times, and the worm passed after the last evacuation. Head looked for, but none found. No more tape-worm seen afterwards.
12	40	Tape-worm known for nine years.	Had taken turpentine and castor oil without any result; no worm being voided by it.	Oil of male-fern, 2 drachms, in pimenta water and acacia mixture at night; castor oil next morning. Fourteen yards of tape-worm passed two hours after the fern draught. The castor oil brought away about twenty-four disjointed segments.
13	42	Tape-worm of "two or three years standing."		Senna draught immediately. Oil of male-fern, 1 dr. in pimenta water, etc., at bed-time; and repeated next morning. Eight yards passed after the second dose of the fern oil. Turpentine and castor oil given afterwards, but no more tape-worm passed.
14	20	Tape-worm several months.		Oil of male-fern, $1\frac{1}{2}$ drachm, in pimenta water. Six yards of the worm passed about an hour and a half after the draught.
15	10 $\frac{1}{2}$	Tape-worm known above a year and a half ago; and twice brought away within that time.	Had for a time taken compound scammony powder on alternate nights. Also some powder with calomel, and turpentine and castor oil, repeated four times without result.	Oil of male-fern, 20 minims, in acacia mixture, 2 drs., and pimenta water, 6 drs., at bed-time. Half an ounce of senna draught in the morning. A "very large" tape-worm passed shortly after the senna was taken.
16	33	Tape-worm known for one year. Had four brought away, of which one was twenty yards long.		Oil of male-fern, $2\frac{1}{2}$ drs.; acacia mixture, 4 drs.; pimenta water to $1\frac{1}{2}$ oz., at bed-time. Castor oil, 1 oz., next morning. "Large worm" brought away before the castor oil was taken. The fern oil draught caused pain in the bowels one hour after it was swallowed, but nothing more.
17	20	Tape-worm known for eight months. One passed of two feet in length.		Oil of male-fern, 2 drs., acacia mixture, 3 drs., peppermint water to 2 oz., at bed-time. Castor oil next morning. Several yards of worm passed before the castor oil was taken.
18	3 $\frac{1}{2}$	Tape-worm known for one year. Four months ago passed a worm of four yards in length, after taking the syrup of senna. Fragments seen daily.	Syrup of senna, without any important result.	Oil of male-fern, half a drachm, in pimenta water, at bed-time; 3 drachms of castor oil next morning. The result not known.
19	20	Tape-worm known for two years.		Oil of male-fern, 2 drs., in pimenta water and acacia mixture at bed-time; castor oil, 1 oz., next morning. A "very long" tape-worm passed ten hours after the fern draught, and before the castor oil was taken. No uncomfortable effects.
20	21		Had taken a drachm and a half of kamela powder, followed by castor oil; but only a few segments of the worm brought away.	Oil of male-fern, 2 drs., in pimenta water and acacia mixture at bed-time; 1 oz. of castor oil next morning. About $3\frac{1}{2}$ yards of the tape-worm brought away after the castor oil was taken. The draught and the oil were repeated; and about the same length of the worm evacuated. The draught and oil were given a third time, and "another long worm" passed.
21	26			Oil of male-fern, 2 drs., in pimenta water and acacia mixture at bed-time; castor oil in the morning. "Two strings of three or four yards each" of the tape-worm passed before the castor oil was taken.
22	21	Tape-worm several months.		Two drachms of oil of male-fern in pimenta water brought away a "large number" of the joints. Thought herself well. Not seen again for 3 months, when the "worms returned." Took $2\frac{1}{2}$ drs. of the oil at bed-time, and a "very large" tape-worm brought away before the castor oil was given on the following morning.
23	34	Tape-worm known to have existed above four months; and three or four feet had been passed at a time without medicine. Accustomed to eat much bacon, but no raw meat. Not known to exist in any other members of the family.	Had taken gin and rue on a fasting stomach, but only a few occasional joints of the worm passed afterwards. Took the oil of turpentine and castor oil after colocynth pills, and a quantity of yellow stuff brought away like the yolk of an egg, but in a "stringy state".	One ounce of castor oil at bed-time; and on the following morning, two drachms of the male-fern oil with acacia mixture and pimenta draught. The castor oil acted twice before morning, but no worm was passed. Three hours after the male-fern draught was taken, the bowels acted five or six times, and six or seven feet of the worm were voided, but no head was discoverable. There was "a good deal of pain" in the abdomen before the worm came away, but none afterwards. The back has, however, been weak since. The castor oil and male-fern draught were again given, but no fragments of the worm parted with.
24*	56	Tape-worm known to have existed for upwards of a year.	Had taken "every kind of medicine".	One ounce of castor oil at night, and a drachm and a half of the oil of male-fern with the mucilage and water the following morning. A very large tape-worm was evacuated in the course of the day; and now, for above a year, there has been no return.

\* This case was not a hospital one, but that of a private gentleman, to whom, at my recommendation, my colleague, Mr. Tatum, gave the oil of male-fern.

On reviewing and considering the above table of cases, it will be at once obvious that the oil of male fern was, at any rate, most useful in causing the death and expulsion of long lengths of the worm. In many cases, the patients had not measured or estimated its length; but it will be seen that in one instance the worm expelled had been twenty-four yards long (Case 2), and in another no less than thirty yards long (Case 3). In a few instances, the existence of the worm had been known for a number of years, as for nine years (Case 11), for ten years (Case 1), etc.; but, in the average number of cases, they had been experienced from between one and two years. The ages of the patients will be seen to vary from 3½ to 57 years.

I regret much that my information is so deficient as to whether or not the root of the worm—the anchoring part, as Dr. Gull aptly terms it—that commonly termed the head—had been passed. In two cases (1 and 6), it is most probable that the head or root was passed. The extremely small size of this, the attached extremity of the worm, the carelessness and inefficiency with which it is of course often sought for, the scanty domestic accommodation enjoyed by the poor, are all circumstances which may fairly be supposed likely to obscure our attempts at determining whether this part has been at any time voided along with the general mass of the worm. I can entertain no doubt that the fine and comparatively pointed termination of the *tænia* is often got rid of—the entire worm, in fact, passed—without the fact being absolutely established.

As respects the action of the oil of male fern, the table, I think, shows pretty well what may be expected of it.\* Out of the whole of the twenty-four cases in which it was given, in only two cases was there any doubt as regards its poisonous and expellent action on the intestinal worm; and in one (Case 8), seeing that eight yards had been passed but a short time previously, it is not unlikely that there was no worm to be expelled.

As regards the period at which, after the male-fern oil had been swallowed, evacuation of the worm was produced, it appears that out of the twenty-four cases (excluding the two cases 4 and 8, before denominated as being doubtful as regards the action of the male fern, and one case, 18, in which no information whatever upon this point was gathered from the patient), in twelve cases the worm was expelled within a short time after taking the remedy, and before the castor oil or other subsequent dose was given; in one case (13), it brought away the worm in one hour and a half after having been swallowed; in another case (18), in two hours afterwards; in another case (23) in three hours.

Touching the action of the remedy upon the patient, irrespective of its vermicide and vernifuge properties, it will be seen that, in by far the majority of instances, this action was not in any degree or manner troublesome or disagreeable. In Case 10, the patient, aged 21 years, was described as having been rendered "very ill" by the medicine; in Case 11, as being made "ill all over", "weak, and trembling"; in Case 23, a "good deal of pain" was complained of when the worm was voided; and in Case 16, pain was experienced in the bowels about an hour after the male-fern had been taken. But, in by far the majority of the cases, it is expressly stated that no discomfort resulted from the medicine; and in none other were any complaints of it made. In Case 11, that wherein so many unpleasant effects were experienced during the action of the drug, it is noticeable that the worm was only expelled after four doses had been taken.

Cases 1, 10, and 12 would appear to show as decided

a superiority in the vermicide action of this medicine, compared with turpentine, as it is superior on the score of taste and agreement, etc.\*

Such are the results which may be elicited by a consideration of the table, regarding the utility of the oil of male-fern in the treatment of *tænia*. I hope to continue to give this remedy in such cases; taking care, if possible, to learn all particulars regarding the mode of life, kind of food used by patients, and specially with reference to the eating of raw meat, ham, bacon, sausages, etc.† I shall also take the precaution, which I would recommend to others (following the custom adopted with the nurses at Guy's Hospital), of promising a premium upon every "root" or head of the worm brought to me by the patient, so as the better to secure them; and, when possible, to admit the patients as in-door patients for a day or two, for the purposes of observation.‡

I will now pass on to make one or two observations which my notebook suggests respecting the uses of other remedies in tape-worm. Thus I find, amidst a great number of other cases of which I have record (but so imperfect in various ways that I could not adduce them along with those placed in the table), that the oil of male-fern has certainly acted vigorously and abundantly in the destruction and expulsion of long lengths of the *tænia* when the *kamela* (written also *kamayla*, *kamala*, and *kamela*) has failed. The form of *kamela* which I used was the tincture, two drachms being the medium dose for an adult. In one case—a child, aged 4 years—after in vain trying the tincture of *kamela*, forty drops of the male-fern oil, in mucilage, syrup, and mint-water, caused the expulsion of ten yards of the worm within three or four hours after the medicine had been administered.

I have also given the powder of the *rotterlia tinctoria*, in about two-drachm doses, mixed with honey or mucilage, with the effect of expelling lengths of the *tænia*. In this dose it has been longer, for the most part, before producing its specific action, than the male-fern oil. In one case in which I gave the *rotterlia tinctoria*, it is not unworthy of remark that the patient complained that, when the *tænia* caused intestinal irritation, in addition to a "mistiness in eye-sight", a gnawing pain at the upper part of the abdomen and pain in the forehead, he very frequently experienced "red blotches", to use his own expression, on the forehead and nose. In this case, I find from my notes that no sickness or uneasiness ensued on taking the *rotterlia tinctoria* powder. In other cases, also, this drug has been noticed as acting without griping or discomfort of any kind.

Again, I have given the *kouso* in ample (half-ounce) doses, but with variable (in some cases quite unsatisfactory) results; also the *santonine*, with, as yet, negative results. But I have reason to think that my doses of the latter drug have been too small for the purpose. I propose trying it in larger quantities. I believe it may be safely given in ten or fifteen grain doses.

On one occasion, I found that a two-drachm dose of the extract of *taraxacum* brought away a large number of the *tænia* joints, the presence of which within the intestines had been unsuspected. It is possible that this vegetable may be rendered available, in suitable doses

\* I am having capsules containing the oil of male-fern made by Messrs. Bullock and Reynolds.

† I cannot forbear referring to a case related in *Virchow's Archiv*, Bd. xxv, and quoted by myself at page 255 of the number of the *British and Foreign Medico-Chirurgical Review* for January 1863, in which the existence of trichinae in the body might probably have been connected with the patient's frequent habit of killing pigs and placing the bloody knife in his mouth, in addition to his custom of eating sausages, etc.

‡ Dr. Hyde Salter tells me that he takes the precaution of having the faeces passed through a muslin bag or sieve, so that they can be most carefully scrutinised; and this plan is worthy of imitation.

\* Had my notes afforded me all the necessary materials, I should have constructed my table of cases in accordance with the scheme or table drawn up and introduced into this JOURNAL (see November 22nd, 1862) by Dr. Fleming.

and form, for the expulsion of intestinal worms; to which, indeed, all "bitters" appear to be inimical. In another case, a tapeworm was expelled after a large quantity of very strong coffee had been drunk.

There is another remedy of which I am about to try the effects, in consequence of its strong recommendation by Friedrich of Heidelberg; and that is the picrom-nate of potash (*Kali picronitricum*)\*.

I may remark, that it would appear that in certain cases there is an attempt on the part of the bowel to dislodge the worm, apart from medicine exhibited. Thus I know of one, a private case, in which for many years the patient has had the tapeworm, and who, every few months, experiences violent griping, with nausea (never vomiting) and diarrhoea, for about half a day, with concomitant expulsion of several yards of the worm. He has never found the root or head of the animal; but he does not appear ever to have sought for it very systematically. In another case of which I have notes, the patient observed that, contrary to what is usually thought to be the case, he had had three worms of large size expelled within a short period of each other, in each of which the head was found. This observation, though stated honestly by the patient, may, of course, have been erroneous.

More than once I have found that the *tænia* and the *ascaris lumbricoides* have existed in the human bowel at the same time.†

With one more remark I will conclude, and it is one which may possibly have a practically beneficial effect; and that is, that I think there may be reason for believing that the *tænia* may be communicated to infants and children from others, and in the following manner. In almost all cases, there is reason to think that a *tænia* does not exist very long within the intestine without portions or joints being passed, not only by stool—i.e., with the feces—but also by their spontaneously working their way through the anus, and "skeddadding" (to use an expressive Scotch phrase) from the person, adhering to the garments, or falling on the ground. Now, I have known cases in which there is reason to think that these fragments, which soon desiccate, shrivel, and become reduced to a small brownish-coloured mass, may have been picked up by children, often crawling infants, who are ever ready to pounce upon and put in their mouth every crumb or crumb-like substance which they can see, and thus have been introduced into the digestive organs. I have no certainty of this; but I think it is a point worthy of consideration and attention, and one to be mentioned to parents in cases where the *tænia* is known to exist in any members of a family.

I hope shortly to be able, if permitted, to produce through the medium of this JOURNAL some observations with regard to the use of strychnia in the treatment of disease, gathered from hospital notes.

\* See the case before quoted from *Virchow's Archiv*, etc.

† On one occasion, a patient was induced from some cause or other to bring me, in addition to the *tænia*-joints which he had really voided, a large earth-worm, which he pretended to have passed along with the other. The deception was recognised without trouble, to the surprise of the patient.

**MUNIFICENT LEGACY.** The Marquis of Lansdowne, the late Lord-Lieutenant of the county of Wilts, has, by a codicil to his will, bequeathed the handsome sum of £3,000, free of legacy duty, to the Salisbury Infirmary.

**CESAREAN OPERATION.** This operation has been lately performed by Dr. Greenhalgh, at St. Bartholomew's Hospital. Delivery *per vias naturales* could not be effected, in consequence of a tumour attached to the sacrum. The woman was at the seventh month of pregnancy. The child was alive when taken out; but survived only a short time. The mother died about sixteen hours after the operation.

## Original Communications.

### THE LARYNGOSCOPE AND ITS CLINICAL APPLICATION.

By THOMAS JAMES WALKER, M.D. (Lond.), etc., Surgeon to the Peterborough Infirmary and Dispensary.

#### II.—INSTRUMENTS EMPLOYED IN LARYNGOSCOPY.

THE instruments which I am now about to describe include not only the very simple laryngoscope itself, but also certain accessory apparatus, which is occasionally required to enable us to throw a sufficiently strong light on to the mirror placed at the back of the fauces; much of the success of laryngoscopic observations depending on the attention which we pay to the illumination of the pharynx. Though the same mirror which we use as a laryngoscope serves to reflect the image of the upper part of the pharynx and the nares, an additional instrument, which we may call a palate-spatula, is required for the examination of these regions; and a combination of this spatula and of the mirror into one instrument constitutes a rhinoscope. The most useful form of this instrument, together with other apparatus for the local treatment of laryngeal, pharyngeal, and nasal affections will be also described.

The laryngoscope is simply a small mirror, placed on a stalk attached to its margin at an angle of from 120° to 150°. The stalk is of metal for about three inches and a half from the mirror; the remainder being a small wooden or ivory handle about three inches long, into which the metallic portion slides. Usually the stalk is straight through its whole length of about six inches and a half, but made of flexible metal in order that it may be bent at the will of the operator; in the margin the laryngoscope is figured which I constantly employ, and I recommend an instrument with similar curves in the stalk as the most useful. (Fig. 2.)

Fig. 2.—Laryngoscope mirror. (The engraver has incorrectly made the handle straight instead of curved, and has represented the angle between the mirror and the stalk too obtuse.)

The mirror itself admits of variety in form and size. Czermak and his pupils use commonly a square one with the corners rounded off and the stem attached at one of the angles; others employ an ovoid mirror, the

stem being attached to the round end of the oval. The most generally applicable form, however, is the circular; and with two mirrors of this form, one about an inch, the other an inch and a quarter in diameter, the practitioner will succeed in examining the interior of almost any larynx.

In selecting the instruments, moreover, attention must be paid to the material of which they are formed. The mirrors are made of polished steel, and of glass coated with amalgam. The former material forms an excellent reflector as long as it remains bright, and is, perhaps, less obnoxious to damage by heat than the latter; but it requires great care to prevent its rusting, and it too readily parts with its heat; on the whole, therefore, a mirror made of thin glass coated with carefully prepared amalgam, and backed with German silver or some similar material, is best. Careful preparation is requisite, or the amalgam becomes cracked from the frequent exposure to heat to which the instrument is subjected. A certain amount of solidity is necessary; otherwise the mirror, cooling too rapidly when placed in the fauces, becomes dull from the deposit of moisture upon it.

This is the only instrument essential to obtaining a view of the interior of the larynx, when circumstances admit of our having the sun's rays falling direct on to the back of the fauces; it is seldom, however, that their direction is satisfactory without the aid of some simple reflector to turn them from their normal course. The most excellent illumination is obtained by placing a looking-glass about eight inches square on a table or the window-sill, about a foot or so below the level of the patient's mouth, and at a few feet distant from him, sloping at such an angle that it catches the sun's rays, and reflects them on to the back of the pharynx in a line corresponding with the axis of the buccal cavity, when the head is held erect, and the mouth opened as widely as possible. Although, for reasons which I shall give directly, the illumination of the fauces by the sun's rays is much to be preferred, it is evident that, unless we are able to apply the laryngoscope under other circumstances than those of sunshine and a convenient window facing the sun, etc., the instrument is of but little practical value. Garcia employed only the sunlight in his observations; and it was Czermak who first conceived and carried out the idea of concentrating diffused daylight and the light from a lamp, so as to make it available for illuminating the larynx. There are two distinct plans for concentrating the light: the first, when the patient is placed with his back to the source of light, the rays from which falling upon a concave mirror placed in front of him are thus concentrated and reflected into the pharynx; the second, where the lamp is placed in the front of the patient, and the light passes through a lens or other concentrating medium direct into the mouth of the patient. The concentrating apparatus of Czermak consists of a slightly concave glass mirror, about three inches in diameter, and having a small hole in the centre of it, through which the observer looks, when the mirror is held before the eye. This mirror may be supported in the hand, as is the ophthalmoscope; but it is much more conveniently attached to the head in some method. Czermak at first used it attached to a strap which he buckled round the forehead; but he now employs the mirror set on a short metallic stalk, which is fixed by a screw to a short piece of wood, the mouth-piece, held between the teeth at such a height that the hole in the centre is on a level with the pupil of the eye. None of our associates should be tempted by the circumstance that this contrivance bears Czermak's name, to choose it as the one they will employ. Even those with perfect teeth will find the fatigue of holding the jaws firmly closed, the interference with speech, and other inconveniences, sufficiently great to check them at the very outset of their laryngoscopic re-

searches. Much more convenient than this apparatus is that of Semeleider, in which the mirror is attached to a spectacle-frame by a stiffly working ball and socket joint; in the eyes of the spectacle-frame, glasses can be inserted to suit every sight. A plan, which I suggested in 1860 to a Viennese instrument-maker, which has since been carried out, is to have the mirror attached by a ball and socket joint to a spring which fastens on to the head; one pad having the mirror attached pressing on the forehead, the other resting at the back of the head as in a fencing mask.

In all of these instruments the mirror is of glass coated with amalgam and backed with metal; it is slightly concave, so that the most brilliant illumination is obtained when the object is placed about eighteen inches in front of it. In using this mirror the patient is placed to the side and a little in front of the lamp or other source of light, the rays from which, passing by his shoulder, strike the mirror in front of the eye of the observer, and are concentrated by it in the pharynx. Much to be preferred, for reasons which I shall subsequently give, to this mode, of illuminating the fauces by reflected light, is that in which, the light from a lamp or candle being placed in front of the patient, its rays are concentrated and fall directly on to the fauces, without the use of a reflector to alter their direction. This was the plan adopted by Dr. Stoerk of Vienna, and also by Tuerck; the concentrator they employed being a globe of glass about six inches in diameter, and filled with water.

The engraving (Fig. 3) shows the mode in which I have had this fitted into a frame of metal, which is much

Fig. 3.—Apparatus for concentrating light.

more convenient than the cumbersome wooden affair used by Stoerk. By means of the screw (*a*), the cross-bar (*b, b*), and with it the globe (*c*), which constitutes our lens, is raised or depressed. This globe must be placed close to and immediately in front of the lamp placed on a table behind the observer. A very brilliant light is thus obtained, which is most concentrated at about twenty inches from the globe, but is sufficiently bright to light up the larynx, both much

nearer to and at a greater distance from the globe; of course, by altering the relative heights of the lamp and the concentrator, we can cause the rays of light to fall higher or lower as we please. The objection to the use of this concentrating lens in place of a reflector is simply that it is too cumbersome to carry about with us to our patients' houses; we may, however, often replace it, when the examination does not take place in our own consulting-rooms, by a plain water-bottle, which, when filled and raised to the level of the lamp and placed in front of it, on a box, or books, or something equally within reach at the majority of houses at which we visit, is an efficient substitute for the globe and frame.

The practical advantages of the direct illumination of the fauces as compared with that by means of a reflector attached to the head of the observer are very great. In the first place, the illuminating apparatus being altogether independent of the body of the operator, he can, as long as he does not bring his head immediately in front of the lamp, move his head and body as may be required, and he can bring his eye nearer to, or remove it further from, the object he is examining, as he wishes. On the other hand, with the reflector attached to the head, the observer cannot move without withdrawing the light from the fauces, and he cannot bring his eye nearer than about eighteen inches to the pharynx without diminishing the intensity of the illumination; and, since the part of the larynx which he is examining is still further from him than the laryngoscope, it must be beyond the range of ordinary accurate vision—a circumstance which interferes seriously with the observation of minute points of difference in structure, colour, &c. Secondly, even supposing that the reflector did not labour under the disadvantages just alluded to, there is the fact that the same flame will give, with the concentrating apparatus to which I give the preference, a much more brilliant light than when concentrated by the reflector.

The inconveniences attached to reflectors for illuminating the larynx, have induced Dr. Moura-Bourouillou, the author of a work on *Laryngoscopy*, to employ a concentrating lens of glass. This is about two inches in diameter, and has its principal focus at about three inches distance. It is attached to a lamp by means of a collar of copper, on which it is supported by an arm having two joints. The lamp, of course, in employing this instrument, is placed in front of the patient as with the globe of water above described; but the focal distance of the lens being so short, not only the concentrating lens, but the lamp itself, must intervene between the mouth of the patient and the eye of the observer; hence a screen is necessary to prevent the bright light of the lamp from interfering with the view of the larynx seen beyond it; this is attached to the collar of copper on the opposite side to that to which the arm supporting the lens is fixed. Although I have no practical experience of this instrument, it appears to me that it possesses many disadvantages as compared with the globe concentrator which I have described. A perfect apparatus would be a glass lens properly mounted, the focal distance of which should be the same as that of the globe of water, which should condense the light to an equal degree, should be as cheap, more portable, and altogether more convenient than the apparatus I have described. Although I have thought it right to mention the several modes of illumination employed by those who are devoting special attention to the laryngoscope, I recommend only certain instruments for purchase by those who wish to pursue the examination of the larynx.

As I have already said, the brightest image is obtained when the sun's rays are thrown into the larynx. For examination with such light, we require simply our laryngoscope, and a common looking-glass to change the direction of the rays. The sunlight failing us, we should employ the glass globe of water, supported in a

convenient frame. And, lastly, in cases where we can neither employ our own globe of glass, nor extemporise a similar condenser from a water-carafe, we must avail ourselves of a concave reflector, which should be either that attached to the spectacle-frame of Semeleder, improved as it has been by our own and the Parisian instrument-makers, or that attached to the spring crossing the head, as suggested by myself.

[To be continued.]

## Reviews and Notices.

STATISTICS OF INSANITY; EMBRACING A REPORT OF BETHLEM HOSPITAL FROM 1846 TO 1860 INCLUSIVE. By W. CHARLES HOOD, M.D., Resident Physician of Bethlem Hospital, &c. Pp. 122. London: 1862.

THIS work is an amplification of a decennial report presented to the Governors of Bethlem Hospital in 1855. The statistics of the subsequent five years have been added; and those already given for the preceding ten years have been carefully revised.

The tabular statements and commentaries given in this volume refer to the following subjects: Patients admitted as Curable; Age; Sex; Domestic Condition; Social Condition; Education; Religion; Residence; Apparent and Assigned Causes; Duration of Disease before Admission; Number of previous Attacks; Influence of the Seasons; State of the General Health of the Insane; Form of Insanity; Causes of Death and *Post-mortem* Appearances of the Insane; and the Treatment of Insanity.

During the fifteen years embraced in these statistics, we find that 3668 patients were admitted as curable, of whom 2018, or 55.01 per cent., were cured; while 222, or 6.05 per cent., died. In the last five years—1856 to 1860—the admissions were 939; the cures 539, or 57.40 per cent.; and the deaths 48, or 5.11 per cent. These results show a favourable contrast with the aggregate of the hundred years ending December 31st, 1860, in which the recoveries were 43.45 per cent., and the deaths 7.53 per cent. of the total number of admissions—19,649.

Dr. Hood has given, as the most correct, although only approximative, standard of comparison at his disposal, a table drawn up in 1854 by Dr. D. H. Tuke, exhibiting the comparative statistics of various asylums in Great Britain and several continental countries. From it we gather the following data as to recoveries.

Eleven Dutch Asylums for pauper and private patients, gave 1000 recoveries in 3087 cases, or 32.40 per cent.

Nine English County Asylums receiving paupers only, 5746 recoveries in 15,548, or 36.95 per cent.

Six English County Asylums receiving private and pauper patients, 3627 recoveries in 7738, or 46.87 per cent.

Metropolitan Licensed Houses, 1839-43 (more than half paupers), 1501 recoveries in 5850, or 25.65 per cent.

The York Asylum (one-third paupers), 1814-44, 475 recoveries in 1375, or 34.54 per cent.

The York Retreat, 1796-1847, 292 recoveries in 593, or 49.24 per cent.

Seven Scotch Chartered Asylums (more than half

pauper), 3021 recoveries in 7130, or 42.37 per cent.

Ten Irish Asylums (pauper), 4957 recoveries in 10,255, or 48.33 per cent.

Five American Asylums (private and pauper), 4062 recoveries in 8675, or 46.82 per cent.

Charenton (private patients), 1826-33, 518 recoveries in 1557, or 33.26 per cent.

Siegburg, 1825-40 (only curable patients), 347 recoveries in 1129, or 30.73 per cent.

It must be remembered, that the results would be probably more favourable if the statistics of these institutions were brought down to the present day. Still the proportion of recoveries at Bethlem Hospital is great; and this result is in part accounted for by the rules of the institution, which

"Render ineligible all applicants who have been insane for more than twelve months; all who are afflicted with paralysis, epilepsy, or any other form of convulsive disease; all who have been discharged uncured from other hospitals; and all aged and weak persons, and pregnant women."

Another regulation provides for the discharge of the patients, if uncured a year after their admission. Dr. Hood informs us, however, that practically this rule is often set aside on the recommendation of the resident physician, so as to allow those whose cases allow a hope of recovery to remain in the hospital fifteen or eighteen months. He believes that many patients discharged uncured would recover if allowed to stay in the hospital above twelve months; and gives in support of this view a table from Esquirol, who has shown that, of 2005 patients, presumed to be curable, admitted into the Salpêtrière during a period of ten years, 604 recovered during the first year, 497 in the second year, 71 in the third, and 46 during the succeeding seven years. Sometimes even more patients were cured in the second year than in the first. After some further observations on the subject, Dr. Hood expresses his opinion that

"There is no doubt that the rule which limits the time of recovery must operate unfavourably with regard to the interests of some of the patients now discharged uncured, a considerable number of whom might possibly have recovered, if an indefinite time of residence in the hospital had been allowed them."

The book contains much more valuable statistical matter, which, however, we must be content with commending to the study of those who are interested in psychological medicine.

A SYSTEMATIC HANDBOOK OF VOLUMETRIC ANALYSIS; or the Quantitative Estimation of Chemical Substances by Measure. By FRANCIS SUTTON, F.C.S., Professor of Practical Chemistry, Norwich. Pp. 282. London: 1863.

The volumetric analysis of substances is a process which, from its simplicity, promises to find universal favour among chemists in general, and especially to those interested in the determination of the composition and value of the agents and products used or met with in manufacturing processes, certain of the fine arts, medicine, pharmacy, agriculture, and general commerce. The author of the work before us, impressed with this idea, endeavours to describe the general application of a mode of quantitative analysis which has hitherto been in partial use among us. Volumetric analysis is indeed not alto-

gether unknown to the English chemist; for, as Mr. SUTTON observes, it appears to have been first suggested by Mr. J. J. Griffin and the late Dr. Andrew Ure; and our chemical treatises have for years past described partial applications of this kind of analysis, under the titles of acidimetry, alkalimetry, and chlorimetry. It has also been successfully applied to the determination of the quantities of various ingredients of the urine.

Volumetric analysis is then, according to Mr. Sutton, of English origin; but the working out of the system is due to continental chemists, especially Mohr of Coblenz.

"Mohr has worked out a most elaborate and extensive system of analysis, which must be an inestimable boon to all who concern themselves with scientific and especially technical chemistry. Not only has Mohr done this, but, in addition to it, has enriched his processes with so many original observations, and improved the necessary apparatus to such an extent, that he may with justice be called the father of the volumetric system. His *Lehrbuch der Chemisch Analytischen Titrimethode* is the most complete treatise on the subject, and well deserving the thanks of all students of the science." (P. 17.)

The process of volumetric analysis, as described by Mr. Sutton, consists in the determination of quantities by means of standard or titrated solutions. The word *titrated*, which seems likely to come into common use in chemistry, is applied to solutions whose strength or chemical power has been accurately found by quantitatively testing it by means of other solutions of known strength. In the processes of analysis by measure which we have hitherto employed—such as alkalimetry, acidimetry, etc.—a great variety of standard solutions have been used; but, in the present system, the titrated solutions are prepared on a uniform plan, so as to contain a chemical equivalent of the required test in a thousand parts of solution.

"For instance, suppose it is desired to prepare a normal alkaline solution for acidimetry; the atomic weight of carbonate of soda is 53, therefore 53 grammes of pure and dry carbonate of soda are weighed, introduced into a *litre* flask and dissolved, so as to make exactly the measure of one *litre*. It is manifest that every 100 cubic centimètres" (1000 c. c. being = 1 litre) "of this solution will contain 5.3 grammes of carbonate of soda, and every 10 cubic centimètres, 0.53 gramme. Therefore 100 cubic centimètres will exactly neutralise 4 grammes of anhydrous sulphuric acid; etc."

The standard solution may also be prepared on the ordinary English or grain system; the proportion in the case of the soda solution, for instance, being 53 grains in 1000, so that the solution would be chemically of the same strength as that prepared on the decimal system.

The solution, whether prepared on the grain or on the *gramme* system, should be of such strength that a thousand grains or a *litre* is exactly capable of neutralising or saturating an atomic equivalent of the substance to which it is applied as a test. Solutions of the strength described above are called *normal*; but, to obtain greater delicacy in certain cases, it is sometimes necessary to reduce the strength of the solution to one-tenth; and the solution thus reduced is termed *decinormal*.

The process of volumetric analysis is sometimes direct, sometimes indirect.

"The direct method includes all those analyses where

the substance under examination is decomposed by simple contact with a known quantity or equivalent proportion of some other body capable of combining with it, and where the end of the decomposition is manifested in the solution itself.

"It also properly includes those analyses in which the substance reacts upon another body to the expulsion of a representative equivalent of the latter, which is then estimated as a substitute for the thing required.

"Examples of the first kind are readily found in the process for the determination of iron by permanganate of potash, where the beautiful rose colour of the permanganate asserts itself as the end of the reaction.

"The testing of acids and alkalies comes, also, under this class, the great sensitiveness of litmus allowing the most trifling excess of acid or alkali to alter its colour. The second is exemplified in the analysis of binoxide of manganese, and also other peroxides and oxygen acids, by boiling with hydrochloric acid. The chlorine evolved is estimated as the equivalent of the quantity of oxygen which has displaced it. We are indebted to Bunsen for a most accurate and valuable series of processes based on this principle.

"The indirect or residual method is such that the substance to be analysed is not estimated itself, but the excess of some other body added for the purpose of combining with it or of decomposing it, and the quantity or strength of the body added being known, and the conditions under which it enters into combination being also known, by deducting the remainder or excess (which exists free) from the original quantity, it gives at once the proportional quantity of the substance sought.

"An example will make the principle obvious:—Suppose that a sample of either native carbonate of lime, baryta, or strontian is to be tested. It is not possible to estimate them with standard nitric acid in the exact quantity they require for decomposition. There must be an excess of acid and heat applied also to get them into solution, if, therefore, a known excessive quantity of standard acid be first added, and solution obtained, and the liquid then titrated backward with litmus and standard alkali, the quantity of free acid can be exactly determined, and consequently that which is combined also.

"In some analyses it is necessary to add a substance which shall be an indicator of the end of the process; such, for instance, is litmus in alkalimetry, chromate of potash in silver and chlorine, and starch in iodine, estimations.

"There are other processes, the end of which can only be determined by an indicator separate from the solution; such is the case in the estimation of iron by bichromate of potash, where a drop of the liquid is brought into contact with another drop of solution of red prussiate of potash on a white slab or plate, when a blue colour ceases to form, by contact of the two liquids the end of the process is reached.

"The latter is somewhat less reliable, in point of delicacy, than the others, but nevertheless, with care and practice, is susceptible in most cases of very tolerably accuracy." (P. 21-22.)

Having given a general outline of volumetrical analysis, Mr. Sutton proceeds to describe in detail its application to special instances, arranged under the heads of Analysis by Saturation (including acidimetry and alkalimetry); Analysis by Oxidation and Reduction—a process of very extensive application; and Analysis by Precipitation. He also describes at some length the applications of the volumetric system to the analysis of urine, soils, manures, and water.

We can recommend Mr. Sutton's book, as giving a very good explanation of a process which, if well mastered, will remove most of the difficulty which

has hitherto attended attempts to make quantitative analyses. The apparatus required are neither elaborate nor expensive. Care must, of course, be taken to ensure accuracy in the graduated measures, etc., and purity in the reagents. With these precautions, and with the application of ordinary mental accuracy on the part of the operator, volumetrical analysis appears likely to become extended in application, in proportion as its simplicity and utility become more widely demonstrated.

## British Medical Journal.

SATURDAY, MARCH 14TH, 1863.

### DEATH OF THOMAS SIMPSON, M.D.,

VICE-PRESIDENT OF THE BRITISH MEDICAL ASSOCIATION.

WE regret to learn the death, on February 28th, of Dr. Thomas Simpson of York, one of the permanent Vice-Presidents of our Association. Dr. Simpson filled the office of President during an eventful period in the history of the Association, and will be remembered by many for the ability and courtesy with which he conducted the proceedings of the meeting at York in 1855. Dr. Simpson was in his seventy-fifth year.

### LEGAL ACTIONS AGAINST MEDICAL MEN.

WE should have been glad to have heard that something in the shape of a protective medical association had arisen out of the late medical meeting which was held at Freemasons' Tavern. The persecution to which members of our profession have lately been subjected by actions at law most unjustly brought against them by individuals, who do or do not think themselves aggrieved in reference to medical treatment, etc., is really becoming a serious affair. Week after week, cases of this kind are brought under our notice. And who is safe from liability to such persecution?

The position of the medical man in reference to his patient, and the very nature of the services in which he is engaged with him, render the medical man most obnoxious to persecution of this kind. A patient with a broken leg rises from his bed with a leg not set to his taste, and brings an action at once against his medical man, who may be perfectly innocent of the bad cure; and yet how hard it is to persuade a jury that he is so! And still more, alas! how easy is it to bring half a dozen medical brethren into court to swear that, in their opinion, if the leg had been properly managed, it would not have been shortened, etc.!

A woman dies from apoplexy twenty days after delivery; during the delivery she suffered from severe

hæmorrhage; but made an excellent recovery, until struck down by the apoplexy. Hereupon, medical brethren rush to the coroner's inquest, and give their opinion that the *post partum* hæmorrhage had indirectly caused the apoplexy, and that a medical man, who was accidentally called in during the confinement, was responsible for the hæmorrhage which caused the apoplexy, which killed the woman! Hereupon the husband brings an action; the medical man, frightened at the possible results, compromises the action. Never was there more shameful persecution.

Now, again, we hear of another action to come off during this March assizes at Hereford, against Dr. Lingen. From what we can hear of the case, we believe it to be on a par with those we have already referred to—most unjust and without any kind of justification. We refer to it now, because we do earnestly hope that members of our profession will not be found to enter the witness-box and give evidence affecting the interest and character of one of their profession merely because they are summoned to do so. Heaven forbid that we should interfere with the due course of justice, when any member of our profession renders himself liable to be properly visited by the whips of the law. No; in such case, it would be our duty to assist in bringing the offender to justice. What we enter our strongest protest against is that thoughtless and ready way in which members of our profession are so often found to come forward and assist in the prosecution of a medical brother in distress, however unjust and unwarrantable that prosecution may be. We cannot but feel convinced that it is within the profession itself that we must look for the cause of this frequency with which actions have of late been brought against medical men.

Our conviction is founded on the facts which lie before us. How many of actions of this kind which have of late been brought against members of the profession are there in which the antagonistic finger of a medical man may not be seen? And an especial hardship to which the defendant is subjected in the case is this, that even if he wins his cause he is deeply injured in pocket; for the prosecutor is for the most part a pauperised individual, and the action not unfrequently what is called a lawyer's action.

What is the use of our calling out for Jove to assist us—complaining of defective medical Acts of Parliament and an inefficient Medical Council—so long as this want of *esprit de corps*, or rather as long as this intra-professional spirit of persecution, exists amongst us. What Medical Council or Acts of Parliament can provide us with brotherly love and the spirit of acting with fairness towards our medical brethren? We sincerely trust that we may not have soon again to record histories of the kind here alluded to.

## MEDICAL FRIENDLY SOCIETY.

THE correspondence which we receive on the subject of a Medical Friendly Society shows the interest which is felt about it in the profession. We cannot for a moment doubt that a society of this nature is one very much wanted, and to be desired by medical men. The reasons are obvious, and we have already mentioned the chief one.

The want, or rather the necessity for the thing, being granted, then comes the important question: How is it to be practically worked? What is the kind of machinery best adapted for the carrying into action and the working of such a society? Now it so happens that our Association is by its organisation admirably fitted for its promotion and its working. What we would therefore suggest is, that the Presidents and Secretaries of the different Branches should take the matter into consideration, ascertain the wishes and feelings of the profession in their several districts; and then, fortified by the information thus obtained, should endeavour to establish some joint central power for the purposes of carrying out the objects desired. It is clear that, if such a society is to answer well and thoroughly, it must be wide and comprehensive, and not limited to any particular locality. We shall, therefore, be very glad to learn from the Presidents and Secretaries of Branches any suggestions which they may think well to offer on the subject.

## PROFESSOR GANGEES ON DISEASED CATTLE.

PROFESSOR GANGEES, in the last number of the *Social Science Review*, gives us some interesting details about diseased cattle in this country, which will interest our readers:—

"Before 1842, the mortality amongst farm stock in this country was slight, and did not exceed one per cent. When the importation of foreign stock was sanctioned by Parliament, cattle plagues were prevailing on the continent, and one contagious malady, the foot and mouth disease, was first introduced. It was carried to the British Isles by breeding stock as early as 1840. The lung disease reached us in 1842, and the losses led to general alarm and the institution of insurance offices. These offices have been established in large numbers as mutual and as proprietary companies; but notwithstanding that every attention was paid in preparing proper tables of premium, in starting with a very large capital, and notwithstanding the encouragement given them, they have all failed. Insurance statistics prove that the general loss over the country amongst cattle amounts sometimes to seven per cent., and at least fifty per cent. of this loss depends on imported diseases. The money loss *per annum* in the United Kingdom varies from seven to eight millions sterling, and by pleuropneumonia alone stock to the value of between three and four millions is annually carried off.

"The dairy cows kept in all large towns in the United Kingdom die off at a rate varying from fifty to seventy-five per cent. *per annum*. In the city of Edinburgh, in one year, 1075 diseased animals were slaughtered out of

1800 head of cattle; of these, 971 were slaughtered as human food and 284 sold as pigs' meat. In London alone, the money loss by disease amongst dairy stock amounts to considerably above £80,000 *per annum*. The loss amongst eighty-eight dairymen in Edinburgh amounted to not less than £12,000 in one year. The importation of foreign stock into this country has been the sole cause of the losses by the lung plague, the foot and mouth disease, and the sheep pox; and the trade in diseased animals is disseminating these plagues and perpetuating them on British soil.

"The produce of diseased animals is sold all over the United Kingdom. It is only in exceptional instances that dying or dead cattle are buried. Good evidence\* is supplied to show that this produce is inducing a large amount of disease in man; but as no one buys diseased meat or milk from choice, and is always defrauded when such material is supplied, it is evident that a check should be put on the practices of dishonest tradesmen.

"The contagious maladies might readily be prevented by stopping the admixture of diseased foreign with British stock; and by prohibiting the exposure of diseased animals in our public markets.

"Government should have a Veterinary Department in connection with the Privy Council Office, through which all information as to diseases amongst stock at home, or in the countries with which we trade, should be made available.

"All slaughter-houses should have a professional inspector to facilitate this system; no private slaughtering places should be allowed; and all town dairies should be under a rigid system of professional inspection."

## THE WEEK.

THE appointment of the consulting (really consulting and examining) physician and consulting surgeon to St. Bartholomew's Hospital at Rochester will take place on April 7th. Upon what grounds are such appointments to be made without salary? We would strongly recommend the members of the profession in that city to memorialise the Lord High Chancellor, asking for a revision of the scheme in such respect that the medical officers may be duly salaried. At present, the trustees purpose, as we understand, to appoint the medical officers in accordance with the scheme propounded; pretending that the Lord Chancellor will expect them to try the scheme before applying for any alteration of its details. The Metropolitan Counties Branch of the Association is at present engaged with the subject of gratuitous medical services. Why should it not also memorialise the Lord Chancellor, asking him to alter the custom. Here is a new hospital, well-endowed. Watts's charity contributes £1000 a year at present to help St. Bartholomew's Charity; but Watts's Charity could contribute more if the Lord Chancellor should think proper. The present seems an excellent opportunity for attempting, at least, to do something in the way of breaking through the "villanous" custom of gratuitous medical services.

\* On this point we must beg to differ with Professor Gamgee. What he states *may* be true, but assuredly the *good evidence* of its truth has not yet been supplied. EDITOR.

OUR readers may remember that last year a Mrs. Gillespie was destroyed by a dose of strychnia, which had been accidentally supplied to her as medicine by the assistant of Dr. Fenwick of North Shields. Dr. Fenwick wrote the prescription, which did not contain strychnia. An action was thereupon brought against Dr. Fenwick; and it would seem that he was by law undoubtedly liable in this way for the mistakes of his dispenser. To save further litigation, therefore, Dr. Fenwick thought it well to come to an amicable arrangement with the plaintiff, paying £500 and costs. It thus appears that medical men are as much liable for the acts of their assistants and dispensers as railway directors are for the acts of their servants; and we suppose that the law holds good, whether the assistant be or be not a qualified man. On the face of it, the law certainly seems (as applied in such a case) most harsh and unfair; for what more can a medical man do than provide an efficient dispenser? He cannot be ever at his elbow to see that no errors occur. We apprehend that the fair solution of the case would be this: that no medical man should be liable for the mistakes of a dispenser or an assistant who was *legally* qualified to dispense medicines. The following report of the case speaks volumes in favour of the highly honourable feeling of Dr. Fenwick and his partner, Mr. Peart.

"Mr. Manisty remarked that he had the honour to appear for Messrs. Fenwick and Peart. His learned friend, Mr. Maule, had done justice to them, and had done it in terms which entitled him to the thanks of the defendants, although he had just done what he expected of him. A more painful case than the present had probably never occurred; and it was because of its painful character, and because of the feelings entertained by both his clients, and because of the sympathy which they had for the man who had lost a wife and the children a mother, it was upon those grounds, and those alone, that they had told him to arrange the matter with no niggardly or illiberal spirit. He might have exceeded the bounds; but he thought it right to deal liberally. He had also been instructed, at the same time, to express, on the part of the defendants, their deepest sorrow at the loss which had resulted from the act of some one whom they were responsible for. His learned friend had done that which he need not do now—he had acquitted the defendants of all personal negligence in the matter. He therefore trusted that their reputation would still be upheld, for there had not been the least shadow of a shade to implicate them. The prescription was right, but the medicine made up was wrong. His clients had considered their servants competent as they had proved them to be, but still they were answerable in the eyes of the law. They had agreed to give £500 as compensation, which would be apportioned, £400 to the plaintiff, and £50 for each of the children, one of which the deceased had by a former husband. He trusted that that would be satisfactory to all parties. The jury having given their assent to the offer, the case was concluded."

Among the candidates for the vacant Examinerships in the University of London, is our associate, Dr Birkbeck Nevins of Liverpool, who has applied for

the office of Examiner in *Materia Medica*. We do not know what other candidates come forward for this important post; but we may say without reserve, that we believe that no more competent man than Dr. Nevins could well be selected. Having distinguished himself as a student at the medical schools of Guy's Hospital, Leeds, and Dublin, he graduated at the University of London, taking honours in chemistry; and has subsequently been engaged in Liverpool for nineteen years as a lecturer on *materia medica*, chemistry, and botany. In addition, a hospital experience extending over fifteen years has afforded him ample opportunity for the practical study of therapeutics. Dr. Nevins is also the author of a translation of the *London Pharmacopœia* for 1851, and of numerous scientific and practical papers, some of which have appeared in the pages of this JOURNAL. There is every reason to believe that the duties of Examiner at the University would be efficiently performed by him.

THE *American Medical Times* tells us that when measures were lately brought before Congress to improve the defective condition of the medical department of the army, the senators, instead of fairly judging and advancing the measures,

"Played upon each other's sympathies by relating incidents of the cruelty of medical men to sick soldiers, of their incompetency, and even of their knavery. Not a surgeon was spoken of in a complimentary manner. Of the large number who have been killed while caring for the wounded on the field of battle, there was not a breath of praise. The narration of cases of amputation against the wish and judgment of the parties afforded more congenial topics for senatorial declamation."

THE treatment of the Indian medical officers has excited a feeling of universal disgust in the service. One gentleman, who has been about twenty years in the Medical Department of the Army, and has seen much service, writes:

"I can scarcely find words to express my feelings on the subject. I bitterly regret having ever entered a service in which one is subjected to such uniform want of consideration. It is useless to trouble you with a long string of complaints and grievances; all I ask for now, above everything else, is to be relieved from this state of uncertainty, that we should at once know what our fate is to be in the so-called amalgamation. One can then make up one's mind as to whether or not it is worth while to remain longer in India."

In his address, just delivered at the fifty-sixth annual meeting of the United States Medical Society, the President said:—

"Our profession is now, I believe, in a more sound condition than at any previous time. The standard of education in our principal medical schools is higher, and pupils go forth much more thoroughly educated than a few years ago. The war, with all its evils, is exercising a salutary influence in the medical profession. The examinations for admission to the medical service of the army and navy set up a high standard of excellence, and

as this service presents a most desirable career for young men, a strong inducement is held out to students to strive to come up to it. The benefit of these examinations is thus made to reach not only those who are successful in their application, but also all those who, though they fail, yet have tried to prepare for them. Their influence on the medical colleges is also most excellent, for students wishing to prepare for difficult examinations, will go to those colleges which afford the most instruction and not to those in which degrees are most easily obtained. They have already led to the establishment of a chair of hygienic and military surgery in some of our colleges."

THE mania for new medicines at the present day is surprising, especially when we consider how little we know of the actions of the hundreds we already possess. Here is another—*elatine*—an aqueous solution of tar. "It has a fine topaz-colour, a pleasant taste and smell, and is an energetic remedy."

Dr. Pauli of Landau, while engaged in an operation of strangulated hernia, in a case where the intestine was gangrenous, pricked his finger with a needle. The medius of his left hand began to inflame in the course of a few hours, and so also the lymphatics of the arm. On the following day his finger was amputated. Happily, he afterwards recovered from the unusual accident.

M. Boudin confirms the statement made by many observers before him respecting the influence of the relative age of the parents over the sex of the children. He finds that the male sex predominates when the father is older than the mother; and that the female sex predominates when the mother is older than the father; and that the sexes are about equal—that of the female, however, slightly predominating—when the father and the mother are of the same age.

M. Diday of Lyons has announced the delivery, in Paris, of three lectures on the Natural History of Syphilis.

Dr. Joret recommends the following way of administering croton oil internally. A drop of the oil is dropped upon a piece of sugar, which is then pulverised and mixed with a certain quantity of starch. The mixture is then divided into six or eight powders.

Professor Zippe, the veteran of Austrian mineralogy, died a few days ago at Vienna. The small band of mineralogists which Austria possesses is made still smaller by his loss.

A new journal has been started in Angoulême, entitled *Le Journal du Médecin de Campagne*—the Journal of the Country Doctor.

Dr. Guggenbühl, who lately died at Basle, has left a sum of 600,000 francs to the Moravian Brothers (*Frères Moraves*), on condition that they keep up the establishment founded by him for cretins, under the name of "L'Hospice Guggenbühl".

## Reports of Societies.

### EPIDEMIOLOGICAL SOCIETY.

MONDAY, FEB. 2ND, 1863.

B. G. BABINGTON, M.D., F.R.S., in the Chair.

ON DISEASES OF THE SKIN DEVELOPED IN SCHOOLS, WORKHOUSES, AND FACTORIES, FROM DEFECTIVE HYGIENE. BY THOMAS HUNT, ESQ.

THE author wished prominently to bring forward the effects of congregating and incarcerating many children or young persons under one roof, of feeding them on one and the same diet, and thus promoting locally the more or less permanent inroads of certain cutaneous diseases; which diseases often subside spontaneously upon the removal of the sufferer from the locality.

These diseases are chiefly the common ringworm (*porrijo scutulata*) and scabies; the former being usually aggravated by the presence of a vegetable, the latter by an animal parasite. He had never visited a workhouse, or a detachment of pauper children, or a large boarding-school occupied by the poor, without observing many cases of ringworm and scabies; one of these two diseases prevailing at one time, the other at another period, and both showing a tendency to pustulation.

These cutaneous plagues will often persist month after month, in spite of the most careful treatment and the most scrupulous attention to cleanliness and ventilation. He had already published an account of an endemic scabies, which infected, for many months together, a large girls' school in the neighbourhood of London, where cleanliness, ventilation, good drainage, good nursing, and good medical care, were conspicuously apparent; but nothing was of any permanent service until an entire change of diet was introduced, together with the daily exercise of the inmates away from the premises.

Accounts of similar endemic difficulties reached the author from medical practitioners who had the charge of institutions of the same character in different parts of the country, and the same kind of treatment proved equally effectual in all of them. In those factories where children are employed, and boarded and lodged on the premises, like occurrences are observed, involving the clean and the dirty, the well-fed and the ill-fed. The doctrine of contagion fails to explain the cause; nor, indeed, is any one imaginable cause to be named that is capable, *per se*, of accounting for all the peculiarities of the case. But it appeared to him that, by duly reflecting upon all the sanitary circumstances in which these children are placed, we may be able to discover an aggregate of influences, so to speak, which not separately, but concurrently, may combine to produce these morbid conditions.

Atmospheric impurity, unnatural diet, deficient exercise, and contagion, are the four conditions which appear to unite their several forces to perpetuate these loathsome affections of the skin. And yet not one of these causes alone ever presents a formidable difficulty in the treatment; neither does either of them exist in any prominent degree in these establishments. There is no sensible vitiation of the atmosphere, no bad smell, no defective drainage, no neglect of ventilation. The diet is excellent in quality, plentiful in quantity, wholesome in character, and correct in its chemical elements. Exercise is allowed and encouraged within the walls of the institution, and contagion is, for the most part, antagonised by care and cleanliness, and very often by individual segregation. So that, considered apart, these causes of disease exist, if at all, in scarcely an appreciable degree. And yet, together, they are

capable of establishing a most formidable cachexia. They poison the blood, producing not only their immediate effects in the form of parasitic skin-disease, but laying the foundation probably of more serious disorders, manifested in after life by the presence of lumbrici, ascariides, tape-worms, pediculi, fungi, hydatids, tubercles, and perhaps cancerous germs, in the various organisms which, under morbid changes, become capable respectively of nourishing these distinctive parasites.

The author then considered the causes referred to singly, and of sameness of diet he said: There is a daily dole of potatoes with boiled mutton, or potatoes without boiled mutton; there is the eternal pea-soup or oatmeal gruel, with so many ounces of bread and so many grains of salt. Oh, what a luxury would a red herring be to those poor creatures, or a lettuce, or an apple, or dish of greens, or carrots, or turnips. Man was made capable of living upon a variety of food, animal and vegetable, fish, flesh, fowl, root, leaf, stem, fruit, and seed. But no man can live on bread alone; nor on mutton chops alone; nor on any two or three articles alone. The life supported by half a dozen changes only, is in a feeble, imperfect, half-poisoned condition.

It appeared to the author, then, that these four causes, atmospheric impurity, sameness of diet, insufficient exercise, and contagion, all of them trifling in degree, are yet capable of working together for evil, and may thus become powerful agents in the promotion and perpetuation of disease. The blood becomes vitiated from the unvarying character of the diet, from impure and stagnant air, from deficient perspiration, and restricted activity of limb, and the agents of contagion triumph over the low degree of vitality which results.

If this be sound pathology, these combined evils will probably be found to play a busy part in the production or aggravation of other diseases, endemic or epidemic in their character. Fortified by an ample, generous, and varied diet, free ventilation, active exercise, and cleanly habits, our junior population might set at defiance cholera, diphtheria, dysentery, and typhus, and probably half the physical "ills which flesh is heir to."

Mr. FRENCH said that his experience of the itch in a London workhouse; viz., that of St. James, Westminster, did not accord with that of the author of the paper that the disease was produced by an uniform diet, or the other circumstances to which he alluded. In that establishment there were about 200, who were fed unvaryingly upon boiled mutton every day, and had been so dieted for many years, who took little or no exercise, and were, in every respect, so circumstanced as to favour the occurrence and maintenance of the disease according to the view expressed by the author; yet these were the very people among whom the disease did not occur. It was a disease frequently admitted into the workhouse for the purpose of being cured, and only spread when sufficient care was not bestowed on the separation of the infected, and this very rarely happened. On the other hand, at the Parochial School at Wandsworth Common, where the diet was varied, where fresh vegetables of every description were freely used, and exercise in the open air was abundantly taken, where no fresh comers were admitted with the slightest papulæ upon them, here the disease would continually break forth, unless the most rigid inspection were constantly observed, the patients with papulæ immediately separated, and active treatment adopted. It is true that neither vesicles nor pustules ever appeared, except in cases where the treatment was purposely deferred in order to afford conviction of its necessity; indeed, nothing but ample experience can convince the mind of a medical observer of the necessity of dealing preemptorily with symptoms of so slight a character as those which furnish the first evidence of itch. He thought that the author attached too much importance to some of the circumstances

which accidentally surrounded the patients as the cause of the disease; and the same remark applied to the conjectures which he hazarded as to cholera being influenced by the same causes.

Mr. HARRIS agreed fully with the author of the paper as to the primary importance of improved diet in all cases of scabies, when occurring in a large number of children, wherever collected. He also cordially subscribed to the opinion that next to an improved diet (especially avoiding all boiled meats), fresh air, and exercise in it, were of primary importance. Cleanliness was essential; but to prevent overcrowding was not less so. Mr. Harris resorted, as the correct treatment of what he believed to be true scabies (but only acknowledging a vesicular or pustular form), to the wash recommended by the Poor-law Board to their medical officers; but which he had used long prior to his reception of their printed formula, in preference to sulphur ointment either simple or compound. The form of wash was thus: "Two pounds of sublimed sulphur, one pound of quick-lime recently burned, and three pounds of water" (to which Mr. Harris added a small quantity of sulphuric acid and common salt when boiled); but the above three ingredients, in these specified proportions, were boiled together for one hour, or until a green colour was produced; then pour off without straining, and keep in stone jars well-stoppered; and this wash applied after a warm bath in which soap had been used would cure scabies in the vesicular form in two days, with only one dressing *per diem*, and the pustular form in four days; and no sheets, blankets, or clothes, would be messed or spoiled; for if rubbed in with a bit of sponge or tow before the fire, it would dry in ten minutes, causing some shrinking of the skin and a smarting warmth; but the cure was most satisfactory. Yet scabies becoming endemic in wards and schools compelled the non-return of the cured patients to their old ground or it would quickly recur. Mr. Harris alleged that numbers alone would not render scabies endemic; but the persistence of a succession of cases in the same ward; and he instanced the workhouse of St. Luke, to which he was medical officer. He was also medical officer to the Orphan School, Haverstock Hill, wherein, with nearly always 400 children, he had never seen a case of scabies, and very little ringworm, the other disease specially mentioned by the author of the paper. Ringworm, like itch, was another term so loosely applied that to Mr. Harris it appeared all children's eruptions were called either ringworm or itch; fifty per cent. of ringworm (so-called) was eczema of the scalp; thirty per cent. was impetigo; and twenty per cent. only was tubercular, strumous, or true favus; frequently commencing as the disease called porrigo decalvans, and passing on into true tubercular ulcers, minute, clustering, confluent. Of the treatment here, he would not speak under such uncertainty that each meant the same thing; but to corroborate Mr. Hunt's views, he would say that an improved diet of roasted and broiled meats was imperative; much exercise out of doors; and but few children in any one apartment, however large. These, conjoined with free ablutions with hot water and soap, would go a long way to effect cures; and the specific treatment might be safely left to each individual medical attendant; never forgetting that in strong solutions of nitrate of silver and iodine we possessed the main elements of local success, and that in steel we had a most energetic and valuable constitutional auxiliary.

Dr. Murchison, Dr. Buchanan, Dr. Hillier, Dr. Seaton, also took part in the discussion.

#### ON RECENT TYPHUS IN LANCASHIRE.

BY G. BUCHANAN, M.D.

Since the great typhus-epidemic in Lancashire at the time of the Irish famine in 1847-48, there has been scarcely any of this disease in the cotton towns. In

1862, however, positive maculated typhus has made its appearance. The disease has been most prevalent at Preston, and next at Manchester. Several cases have been met with in Chorley, a town not far from Preston, and more recently at Accrington, and scattered attacks, still of true typhus, appear to have been observed at Salford and Blackburn.

As the chief interest centres in Manchester and Preston, Dr. BUCHANAN confined his remarks to the outbreaks in these towns. He had visited Preston late in October, under the directions of the Privy Council. The earliest case of distinct typhus he could trace had occurred on July 7th, in a four-roomed cottage, 17, Castle Street, at some distance from the centre of the town. It was not known that the first patient had been exposed to contagion. In this cottage, eight persons had crowded by night into a room whose utmost cubic capacity was 800 feet. They were dirty, underfed, and the boy who first felt ill had also been much exposed to the weather. The boy was removed to the hospital, and returned home on his convalescence. In the last week of August, six other persons were attacked in this house. They were removed and the house closed. Meanwhile, new cases of typhus had occurred in another part of the town, apparently without communication with the former. These were in a district that was afterwards subjected to the chief violence of the epidemic. The locality consisted of very confined and dirty courts, lying low, near the canal, and densely inhabited.

At the end of August, a third neighbourhood, distant from either of the other two, became affected with typhus. A fourth outbreak, apparently unconnected with the rest, was seen in another central part of the town in the middle of September. By the end of this month, cases had occurred in five out of six wards into which the town is divided.

The general progress of the outbreak in the town may be estimated from the following return of reported cases of typhus:—Cases occurring in July, 2; August, 8; September, 23; October (five weeks), 109; November, 89; December, 38; week ending January 3rd, 13—a third more than in the previous week, and double the number occurring in the week ending December 20th; week ending January 10th, 15; and since then a still further increase, though not to any great extent.

At the time of Dr. Buchanan's visit, at the end of October, the House of Recovery (fever hospital), which was constructed for forty patients, contained fifty-two cases of typhus. Afterwards, there were upwards of sixty inmates at one time. In some wards the space for each bed fell short of 600 cubic feet, and the air was here very foul.

At the beginning of November, a wooden building was erected in contiguity to the House, capable of containing sixty patients, with a space of 1500 cubic feet to each. This building was put up in ten days; but there was a lamentable delay before the patients were removed into it at the end of December. In the meanwhile, upwards of twenty persons in attendance on the sick had caught the fever, the medical officer and the master of the House of Recovery being among the number.

It deserves mention, for the sake of those who refuse to acknowledge an epidemic influence that does not show itself on the general death-rate, that in the September quarter of 1862, the mortality from all causes in Preston was very markedly below the average, 464 deaths only being registered, against 607 in the corresponding quarter of 1861. This subsidence was entirely among children under six years, and resulted, there is reason to believe, from the greater care bestowed by mothers on their infants during the time of industrial depression.

The following returns from the parish fever hospital will indicate the progress of the outbreak of typhus in Manchester. In July, 7 cases of the disease were admitted; in August, 8; September, 12; October, 20;

November, 25; December, 17. From December 29th to January 13th, not one case; but on the last-named day, two cases, and since then a few who had contracted the fever in adjoining wards of the workhouse. Scattered cases of typhus have probably occurred in Manchester from time to time, but very rarely since 1847-48. The earliest instance of true typhus in the Infirmary occurred at the end of May, and two cases were admitted in June. At present there is very little typhus in Manchester; but it would be premature to reckon on the complete subsidence of the disease.

Dr. Buchanan referred to his recent report to the Privy Council, "On the Health of the Operatives in the Cotton Towns of Lancashire affected by the Prevailing Distress," for a detailed account of the circumstances contributing to the outbreaks of typhus in Preston and Manchester and other towns. He was at a loss to explain why the typhus influence should have fallen chiefly on Preston. Manchester was exposed to the danger of imported typhus. The limitation of the fever to these towns chiefly was to be ascribed to the strict removal of cases to hospital; the maintenance of a high standard of relief, increasing almost every month; the liberal distribution of bedding and clothing as the winter has advanced; and the almost unprecedented mildness of the weather since November. November, which was the coldest month since the distress began, witnessed the maximum of typhus cases both in Preston and Manchester.

Dr. MURCHISON observed that the society was under great obligations to Dr. Buchanan for the important facts which he had brought before it. The points of especial interest in the communication were two; viz., 1. The circumstances under which the epidemic of typhus commenced; and 2. The circumstances under which it began to subside. As to the first, he could corroborate Dr. Buchanan's statement that true typhus had not been met with at Preston and most of the other large towns of Lancashire for many years before the autumn of 1862. The fever which had prevailed in these towns was typhoid or enteric fever, which was very frequently confounded with, and, when fatal, returned to the registrar of deaths as typhus. In proof of this, Dr. Murchison read an extract from a letter, which he had received in May 1862, from a very intelligent surgeon at Preston, who was well versed in the distinctions between typhus and enteric fever. During four years that the writer had been in extensive practice among the poor of Preston, he had only seen a single case of typhus; but though typhoid fever was far from uncommon, the deaths from typhus, as returned to the registrar, far exceeded the deaths from typhoid fever. Characteristic cases of typhoid fever, which had come under the writer's own notice, had been reported to the registrar as examples of typhus. Dr. Murchison observed that the epidemic of typhus did not commence until after the population had been for many months in a state of great destitution, and that it was unquestionably the indirect result of this destitution. He did not pretend to say that any amount of starvation would in itself produce true typhus; but destitution led to overcrowding, and it was this which generated typhus. In the *Times* of October 13th, it had been stated that numbers of cottages at Preston were untenanted, from the inability of the inhabitants to pay the rents, and that it was the practice for several families to congregate into one house. As many as six different families had been said to be collected in one house scarcely above the ordinary size; and now the society had been informed by Dr. Buchanan that the first cases of true typhus observed at Preston had been in a family of four persons, who had been living in a small room with only 600 cubic feet of space, and who were in a state of extreme want. It was important to observe that there was no evidence that any of these persons had been exposed to the poison of

typhus, nor that typhus had been imported into Preston. In the next place, Dr. Murchison observed that the epidemic at Preston began to subside at the beginning of December, at the very time that the condition of the people began to improve, as shown by the diminished numbers in receipt of relief. Whether the disease, once generated, might not spread by contagion, remained to be seen; but every effort had been taken, on the part of government and of the local authorities, to prevent its spreading. The immense amount of pecuniary relief which had been sent to the distressed operatives in Lancashire, the ability with which this relief had been distributed, and the energetic measures adopted by Dr. Buchanan and others for arresting the spread of the fever after it had commenced, had alone prevented an epidemic of typhus like that which resulted from the Irish famine in 1847. The epidemic of typhus which had been raging for the last fourteen months in London would no doubt also have been prevented, if the condition of the poor in the metropolis had attracted the same amount of public attention as that of the suffering operatives in Lancashire.

Mr. Harris also took part in the discussion.

## LIVERPOOL MEDICAL INSTITUTION.

FEBRUARY 19, 1863.

JAMES HAKES, ESQ., Vice-President, in the Chair.

*Disease of the Tibia.* Mr. HIGGINSON shewed a specimen, for which amputation was performed. The whole shaft of the bone was very much thickened and the structure condensed; there was a history of syphilis many years ago, and mercury and iodide of potassium had both been given largely without success.

*Uterine Hydatids.* Dr. HANNAH shewed a specimen.

*The Stimulant Treatment in Inflammation.* Dr. VASE related two cases that had been recently under his care at the Royal Infirmary, as favourable examples of the treatment of inflammation by stimulants. The first case was that of a man, aged about 20, attacked with pneumonia involving the whole left lung. When brought to the Infirmary, he had been under no treatment, and the disease was in its first stage. The treatment adopted consisted of perfect rest in bed, wine, and carbonate of ammonium. Rapid recovery took place and the crepitating râles disappeared. The patient was here then a young man, in the prime of life, the subject of no exhaustion before, and he was treated with stimulants from the very first.

In the second case the patient was a female, aged 21, and was suffering from acute articular rheumatism. She had been under no treatment before admission to the Infirmary. Dover's powder at night, a mixture containing nitrate and bicarbonate of potash, and a little brandy were given. She did not improve, and in a few days a very strong and distinct friction-sound was heard in the cardiac region. The mixture was continued, and half-a-grain of opium every six hours, and a tablespoonful of Holland's gin every hour were also ordered.

After some days the friction-sound became fainter and less diffused, and has now disappeared, as have also all her other distressing symptoms. The case had not been meddled with before admission, and the patient had recovered under the use of stimulants.

Mr. STEELE said that from these cases we might infer that inflammatory disease may disappear under the use of stimulants; but may it not also disappear without their use? He thought we might come to treat cases with less stimulation.

*Fatal Cases of Jaundice in Early Infancy.* Mr. DENTON read a paper on this subject, and recorded several cases that had come under his care. In the first four cases the subjects of the disease were all children of the same parents. In each case jaundice appeared within two

days after birth, but there was no absence of bile in the stools. The fifth and sixth cases occurred in another family. In the sixth case an abscess formed in the arm, the bursting of which was followed by hæmorrhage, that was controlled at length by laying open the cavity, and applying the pernitrate of iron, but the child did not long survive. The remarkable features in all these cases were the presence of bile in the stools, and the number that occurred in the same family. The symptoms that manifested themselves in some or all of these cases were, jaundiced appearance, in a greater or less degree, drowsiness, languor, fainting, inability to suck, paralysis, twitching, convulsions, hæmorrhage, abscess and fatal exhaustion.

*Jaundice in an Infant.* Mr. HODGSON read a case. A lady, who had previously lost a child from jaundice and convulsions soon after its birth, was confined on November 22nd, 1862, of a fine healthy son, at 4 A.M., after an easy labour. At noon of the same day, the child presented a jaundiced appearance. His bowels had acted; a grain and a half of calomel was administered, and Dr. Grimsdale was called in consultation. No further medicine was given, but cold water was given occasionally for a drink, and the feet were placed in mustard and water, and afterwards wrapped in cotton-wool. He improved; but a month after birth an abscess of unhealthy aspect appeared on the right margin of the anus; at the same time a spot of blood exuded from the navel, to which the cord was still attached. The abscess was opened, and a dark bloody fluid constantly exuded from it; during the night the navel began to bleed freely, and caustic and compresses were applied in vain. Next day the navel, from which the cord had now separated, was transfixed with a needle, and secured with a worsted thread. The bleeding ceased; an ointment containing bismuth, and having powdered tannin sprinkled freely on its surface, was applied to the abscess. Chlorate of potash and a little tincture of muriate of iron were administered, and a few drops of brandy in the intervals of nursing.

In a week the needle came away, and left a healthy surface. The abscess gradually healed. A sudden effusion of blood took place into the left tunica vaginalis, and was slowly absorbed. The jaundice by degrees disappeared, and the child got well.

Dr. GRIMSDALE mentioned similar cases which he had seen, in two of which death took place from hæmorrhage. The cases in which there is a complication of jaundice with hæmorrhage are very fatal. In Mr. Denton's cases there seemed very little tendency to bleed, and in the one case where this feature was seen the bleeding was from an abscess, not from the umbilicus. These cases seem also distinct from the milder form we frequently see, where there is absence of bile in the stools, and from which recovery generally takes place.

Mr. DENTON, in answer to the Chairman, said that in one of these cases the mother was a highly nervous woman, with a tendency to heart-disease; the other was a very delicate woman.

Mr. INING mentioned the case of three children of the same parents who all died of jaundice.

Mr. DENTON drew attention to the remarkable feature in his cases, the presence of bile in the motions.

Dr. VASE said the want of uniformity in the alvine appearances in the cases of jaundice mentioned to-night, made any explanation of these cases almost impossible. In cases where there is any uncertainty as to the presence or otherwise of bile in the motions, it would be very well if an analysis were made.

Dr. WATERS said the pathology was very obscure. Is the bile formed in the blood or in the liver? If it is formed in the blood we may have the biliary apparatus free from obstruction, and still the system in general gorged with bile. The disease may be then in the blood itself.

Mr. SKINNER thought this a blood-disease connected with a hæmorrhagic diathesis.

Mr. HIGGINSON would suggest a remedy for some cases, viz., madder, for which we are indebted to the late Dr. Darwen. It increased the secretion of bile, and might be found useful where obstruction is caused by inspissated bile.

Mr. SWIFT spoke of the usefulness of turpentine in restraining hæmorrhage.

## Correspondence.

### THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

SIR,—I was much gratified to read in your impression of this week such an able leader on the *quæstio vexata* of the title of Dr. You have given a most clear and dispassionate *resumé* of this subject of discussion; and, as a member of the Irish College of Physicians, I have personally to thank you for having more than once in your article done justice to that time-honoured institution. You are perfectly correct in stating that the King and Queen's College of Physicians claims that its charter contains special powers, under which it is enabled to grant the title of Doctor of Medicine. You are also quite right in saying that the College has expressed its readiness, and indeed is quite prepared, to defend this privilege of its Licentiates, if any authority or individual desire to try the question legally.

The London and Edinburgh Colleges, on the contrary, have no legal right whatever to confer the title of Dr.; and still less, of course, to make use of the M.D. appendix; nor, as you justly observe, do these Colleges make any pretence to a claim of the latter kind. I believe I am correct in stating that the Licentiates of the London College have to sign a document, in which they promise not to use the title of Dr. unless they are graduates of an university. If this be true, the non-diplomatised Licentiates cannot surely grumble at their right to the title of Dr. being disputed or even denied; because they have, with their eyes open, accepted the parchment of the College with certain definite conditions that they shall not assume the title of Dr.

It is not, however, my wish to discuss the apparent inconsistency of the London and Edinburgh Colleges, who in former days allowed their Members and Licentiates quietly to assume a title to which they had no right, and now, since the year 1859, which has been aptly termed the year of (*dis*)grace, have suddenly withdrawn it. It is not my desire to comment on the way in which the herd with their £10 notes rushed into the gaping doors of those Colleges, and came out full-fledged physicians. Unquestionably, however, the older members of those Colleges (especially London), who had gained their license by a *bonâ fide* examination, have a just cause of complaint to feel that their names should be enrolled amongst a list of men who have gained the same honour for £10, by having it pinned on to the tail of some Scotch diploma during that famous—no, I should rather say that infamous—year 1859. But this is not my affair; the London and Edinburgh Colleges of Physicians have found themselves on the horns of a dilemma. This must be patent to the whole profession; let them get out of it as best they can.

My chief object now is to assure your readers that the Irish College has got into no such scrape; and if its charter contains privileges which the other two Colleges do not possess, it is only right that your readers should know that in many other ways it is very differently constituted. In the first place, it does not grant its diploma to Licentiates of any Apothecaries' Company. This

rule does not hold good with either of the other Colleges. Again, every Licentiate is required to promise solemnly and sincerely that he will neither "compound or dispense medicines for sale, nor engage in any trade in any part of the United Kingdom."

You know, Mr. Editor, probably as well as I do, that there are many Licentiates—at least, of the Edinburgh College—living in London, who not only dispense medicines for sale, but even trade in sponges and tooth-brushes, etc.; nay, more, I have seen an advertisement in such a "physician's shop", where the letters have been composed of rotten teeth tacked on to a blue card-board. Happily, the King and Queen's College of Physicians have kept aloof from all this; and they do not obtain practice or attract public notice by any unworthy means. They have kept themselves undefiled; and it cannot be denied that the Irish College is now the only pure College of Physicians in the kingdom.

Lastly, without wishing to make any invidious distinction as to the examinations of the respective Colleges, I may perhaps be permitted to say, and it is only just that I should do so, that the King and Queen's College has never opened its doors to Licentiates without examining them; and if any one doubts the nature of the examinations, let him go and try them. The numbers of those who have been rejected out of those who have been examined for the diploma, will contrast strongly with the "low mortality," as it has been called, of the great St. Andrew's rush, and will further show, I believe, a higher ratio than, perhaps, any examining board in this country. The total number of those examined at the King and Queen's College in 1861 was thirty-eight, out of whom seven were rejected; and out of forty-eight who were examined last year, eleven were rejected. Whenever, therefore, you meet a member of the Dublin College of Physicians, you may be sure, that he is not a tradesman, and that he has at least once visited the Irish capital; you may also be certain that he has obtained his diploma by having gone through a more searching examination (even if he were already M.D. of the London University) made by some of the most distinguished and leading members of our profession; for who would not feel proud to have such names as Corrigan, Stokes, Fleetwood Churchill, Neligan, and Hudson, on their diploma?

In conclusion, I will merely congratulate those who, like myself, possessing the diploma, must feel that they have gained one of the first, if not the first, medical qualification to be obtained in the United Kingdom.

I am, etc.,

EMERALD ISLE.

February 23rd, 1863.

SIR,—Permit me, through you, to thank those gentlemen who have replied to my letter, respecting the alleged powers of the King and Queen's College of Physicians, Ireland, to confer the degree of M.D. It is not my wish or intention to cast the slightest discredit upon the Licentiates of this College, who must be regarded as persons misled by representations commonly received and acted on, which they could not fairly be expected to investigate before paying their money for a supposed medical status. I have only one object, and that is truth. I trust, therefore, that both Dr. Foster and L.K. & Q.C. will assist me in eliciting it.

I started with the assertion, that the K. & Q.C.P.I. had assumed the power to confer the degree of M.D., which was not warranted by their charter, nor had they the right to confer such degree by any Act of Parliament. Also, that their license *per se* gives no medical status in England.

The object of the charter was to create a corporate body, which should examine into, regulate, and correct the practice (including that of physicians) and sale of physic in Ireland, and not elsewhere, and nothing more. I found these assertions on the following grounds.

1. That their charter contains no clause giving to this corporation the power to create a Doctor of Medicine or Physic. [An abstract of this charter will be found in a letter published in our JOURNAL of April 27th, 1861.]

2. That the medical corporations have no power to confer degrees. [Vide Judgment of Lord Chief Justice, in case of Mr. Barker.]

3. The form of the license of K. & Q.C.P.I. is worded: "To grant, so far as rests with them, full license to exercise the art of medical science so long as he (the Licentiate) shall well conduct himself." Not saying whether as physician or apothecary, because originally framed so as to suit both.

4. The pseudo M.D. of this College was struck out from the *Medical Register*; and K. & Q.C.P.I. failed by their mandamus to get it restored, or even to shew any right to the title, or that they had or could confer it.

5. I have seen a letter from a late Registrar of K. & Q.C.P.I., in which, in reply to an inquiry touching this question, he says that the prefix of Dr. is merely a courtesy title; but as such, it has never been refused.

6. Sir Hugh Cairns, the late English Solicitor-General, gave it as his opinion, that this College had no power to confer the degree of M.D.

7. In the judgment that was delivered in the Court of Queen's Bench, Ireland, when the K. & Q.C.P.I. tried the question (the Lord Chief Justice and Justices Hayes and Fitzgerald being on the bench), the Lord Chief Justice said: He (Mr. Barker) contended that there was a diploma which entitled him to what he sought; but suppose there was, and supposing the College of Physicians had a right to grant a degree of M.D., they had not granted it.... The applicant had failed to show primary qualification as a Doctor of Medicine by virtue of a degree, and a mere titular qualification would not do.

1. The Acts of Parliament, though they regulate the number, etc., of the Fellows and Professors and their salaries, and appoint visitors of the College, yet they give it *no power* to confer degrees; so that the result clearly deducible is, that the College was not intended to have, and have not lawfully, the power of *creating* physicians, apothecaries, or druggists, but merely of ascertaining that persons so practising were sufficiently skilled to prevent injury to the public health.

The Lord Chief Justice calls the applicant throughout Mr. Barker; and I feel sure that so high a legal authority would not do this offensively. Besides, he says that K. & Q.C. had not conferred a degree in this instance. Now, as this was the case, the College selected for a mandamus to compel the Registrar to restore the letters M.D., signifying Medical Doctor, it is fair to infer that all they could confer, and all that their charter empowered them to enforce, was done in this particular instance; and that if from any cause the College had failed from any technical error, they would have applied for a mandamus in the case of another Licentiate.

Let us turn for a moment to the only published authority upon which the College claims this, to a College unique power, the thought of the Attorney General for Ireland, "I think, etc." This is not sufficient to satisfy, and ought not to satisfy, the medical profession or the public; what we require, and what alone can set this question at rest, is the publication of those clauses in the charter upon which this College claims the power to confer the degree of M.D. As your correspondent L.K. & Q.C. & M.D.I. offers to afford me every facility to try this point in a court of law, I trust he will not object to meet the question fairly by the more satisfactory and far readier course; which is, to publish in your pages those clauses in the charter of K. & Q.C.P.I. upon which the expression of the Irish Attorney General is founded and alleged claim of College based.

I have honestly, and I hope fairly, given the grounds upon which I made my statement. I have no wish to detract from the merits of Fellows or Licentiates of this

College; but I believe it a duty to bring this question before the profession, and I have done so.

I am, etc., A.

March 1863.

### THE TITLE OF DOCTOR.

SIR,—If the vexed question of medical titles admit of being settled on the side of the Licentiates of Royal Colleges of Physicians, your editorial remarks of last week must certainly attain that end; for truly you have not failed to make use of every possible argument which can be adduced in support of their claim. I think, however, you will find that so much remains to be said and felt on the other side, that the difficulty will still longer remain *sub judice*.

There can be but two ways by which non-graduated Licentiates of Colleges of Physicians can claim the title of Dr.: either by right or by courtesy. Dictionary meanings of words, and comparisons between the professional merits of graduates of medicine and Licentiates of Colleges of Physicians, I hold to be altogether idle and foreign to the question.

With regard to the claim by right. It is now generally admitted that no one can legally assume the title of Dr. unless he have obtained the degree of Doctor of Medicine (or of some other branch of study) from a University capable of granting such degrees. The College of Physicians, at least of London and Edinburgh, distinctly acknowledge that they possess no such power; and consequently, that their licentiates have no legal claim to the title or Dr. Hence, the idea of settling the dispute in a court of justice, as has been proposed, seems to me simply absurd. The battle would be between the Universities on the one hand, and Colleges of Physicians on the other, on the ground of a corporate right for which the latter set up no claim.

The claim by courtesy rests on the fact, that it has long been a custom with the public to designate all physicians, even if non-graduated, by the title of Dr. But really, are the circumstances which gave rise to such a custom in any way comparable with such as surround our present difficulty? The non-graduated physician, or, as they are more commonly called, Doctor of Advice, who then received our courtesy, was the exception rather than the rule; he had to undergo an examination and agree to a certain mode of practice which at once shewed him to belong to a different order of the profession from the general practitioner. He was a physician indeed, not only in name—a totally different genus from the Edinburgh Licentiate of the ever memorable year of (aptly called) *disgrace*. As matters now are, the title of Dr. in the eyes of the public gives to its holder a sort of professional superiority; and, when we reflect upon the circumstances and mode in which the Edinburgh qualification was obtained; when we know that many of those who received it were men with but one qualification, and not in any way worthy of a superior designation than their less ambitious neighbours; when we find that the qualification was sought after, not so much to enable its holder to practise as a physician, as for the title with which they believed it to be associated; and when we know that their only claim to the title rests upon our courtesy—can you wonder that we look upon such a custom as “more honoured in the breach than in the observance,” and that we decline to connect a title of so much honour with a qualification of so little worth?

The case of the members of the Royal College of Physicians of London, who received their diploma before the recent changes is altogether different. They, I confess, deserve our sympathy; and, I doubt not, will continue to receive our courtesy. I am, etc., M. B.

February 22, 1863.

SIR,—Notwithstanding the emphatic denial of L.R.C.P.Ed., and F.R.C.S.E., I still believe that I was

substantially correct in the statement I made that “the Manchester Medico-Ethical Association some time ago resolved that a licentiate, not having a degree, was not entitled to be called Doctor.” Although no formal resolution was proposed on the occasion alluded to, when Dr. Stone the Honorary Secretary, brought the subject of the assumption of a medical title without legal claim for discussion before the society, the opinion was all but unanimous against any one without a degree assuming the title; and I appeal to the honorary secretaries to state whether they in their official capacity recognise the rights of licentiates to the title of Doctor. In reply to your editorial note appended to my former letter, I am still unable to comprehend how any honourable licentiate can assume the title of Doctor in the face of the positive statement made by his college that it “never directly or indirectly claimed the possession of any power to confer the title of Doctor; and applicants for its license have been, in every instance in which inquiries were made on the subject, informed, in the most express terms, that no such title was granted by this college” (quoted from the Annual Report for 1861, of the Manchester Medico-Ethical Association.) I cannot think that any one is endowed with much self-respect, who insists upon having what is not his of right; and to my mind there would be a littleness approaching to the ridiculous in the title of “Courtesy Doctor,” were it not that I know it to be assumed, not from a little pardonable vanity but for a purpose not so innocent.

I do not see that the London and Edinburgh Colleges of Physicians are to blame in this matter; the above extract from the “Explanatory Minute of the Council of the Edinburgh College” showing distinctly that it does not sanction the use of the title of Doctor by its licentiates. And we have the Registrar of the London College stating in the JOURNAL that “No [physician as such can properly have rank or title, no claim to these being recognised by authorities treating of precedence, except as founded on the possession of an University degree,” therefore, if any one unjustly uses the title of Doctor it is for the profession—as the colleges have no power to check its abuse—to act, and refuse it to those who have not a legitimate right to it.

As a contrast to your leading article of Saturday last, you will perhaps allow me to give some extracts from two of your former ones. In the JOURNAL of March 1, 1862, you say “We cannot suppose that gentlemen who supply medicines to their patients can claim the rank conventionally ceded to what are called physicians, although they actually by having become licentiates of a college are *de facto* physicians by title.” Also, in the JOURNAL of March 22nd, 1862, you write, “For our own part, we must candidly say, arguing on the principle of a stick being a stick, that we object to give the title of Doctor to those who possess not the doctorate.” Will you inform us, Mr. Editor, what has occurred since you wrote the passages quoted to account for your recent change of opinion? I am, etc., F.R.C.S.

February 23rd, 1863.

### THE DELIVERY OF TWINS.

LETTER FROM JOHN JONES, ESQ.

SIR,—I have read with much interest your observations on the late inquest at Leamington, and think with you that, although the verdict given by the coroner's jury on the case of Dr. Philbrick was not altogether unfair, yet the medical evidence was too hardly pressed and strained against the doctor, and that he is fairly entitled to the sympathy of his professional brethren.

From the evidence, it does not appear whether the placenta belonging to the first child was expelled before the birth of the second. If this were not the case, there would be great liability to hæmorrhage; and the accou-

cheur would not be justified in leaving his patient till the labour was completed by the birth of both children. But if the placenta should follow the child to which it belongs, it might become a question, how long it would be proper to wait before manual interference for hastening the delivery of the second child would be justifiable.

The following case, which came under my notice soon after I commenced practice, was published in the *London Medical and Physical Journal*. It excited much interest at the time, and is noticed in Dr. Ramsbottom's obstetrical work.

A young medical friend called to request me to accompany him to a patient whom he had delivered on the Friday preceding—it being Sunday when he called. He stated that nothing particular occurred to his patient at the time of her delivery; but, on visiting her that morning, he had discovered there was a second child. We found his patient, a strong robust woman, without any unfavourable symptom: the child was a remarkably fine boy. On examination, there was a second child *in utero*.

No doubt, if the existence of twins had been ascertained at the time of delivery, the accoucheur should have delivered before he left his patient. But what was the right practice under such anomalous circumstances? Although the best obstetrical authorities are opposed to a protracted delay in delivering the second child in cases of twins, as no untoward symptoms had occurred in this case, I thought we were not justified in interfering, and decidedly recommended that we should patiently wait and carefully watch for the further operations of nature; and unless hæmorrhage, convulsions, or other dangerous symptoms should occur, not to interfere, however long before the termination of the labour. The passive treatment was accordingly adopted. The patient continued uninterruptedly to improve without the occurrence of any unfavourable symptom. This state continued a fortnight, when labour recommenced, and was speedily followed by the birth of a second boy, healthy and vigorous, but smaller than the first, and about the size of an eight month's fetus. The mother had a very favourable recovery; and it was remarkable that the secretion of milk did not occur till after the second birth.

I am, etc.,

JOHN JONES.

Derby, February 25th, 1863.

### TREATMENT OF TWIN-CASES.

LETTER FROM J. SPROULE, ESQ.

SIR,—Having observed some remarks in your JOURNAL as to the period of time a second child should be allowed to remain after the birth of the first, I am induced, from thirty years experience and constant practice, to forward you a few remarks, which are as true as they are plain.

In the first place, when a second child is in the uterus, and no hæmorrhage occurs, there is no occasion to interfere for twenty minutes, or, if you wish, forty minutes; but at the end of that time, if the uterus did not show some symptom of tonic contraction, I would give a dose of ergot, which will almost in every case bring on a healthy action.

On the other hand, if there be hæmorrhage, sudden or continuous, I would turn, and with success both to mother and child in almost every case. At all events, there would be no danger to the woman, and less to the child, than in allowing it to remain any length of time. Moreover, the parts become more irritable, and the woman weaker and more nervous.

There is no trouble at all in turning the child at an early period; and no danger, for the parts are all in a fit state for the operation. The child is strong; and a good operator will run through with his case in less than an hour, at the outside, from the time when the first child is born.

Most decidedly, if there be no alarming symptoms, a woman may have more time; but if the symptoms were bad, and hæmorrhage continuous, delivery should be instantaneous.

I am, etc., J. SPROULE.

Arvagh, Co. Cavan, February 18th, 1863.

### THE MEDICAL ACT.

LETTER FROM JAMES HEYGATE, M.D., F.R.S.

SIR,—There is so much of truth in a letter from "An Old Associate" on this Act, in last week's JOURNAL, that I crave a space to urge upon the Medical Council the absolute necessity of moving in this matter.

During the presidency of my friend Dr. Robertson (now many years ago), a special and very influential meeting of the Association was held in this central town to promote a Medical Reform Bill; and all the old members must recollect how constantly this subject was mooted at our annual meetings—none advocating it more warmly and more successfully than our excellent friend Sir Charles Hastings. No doubt we were (as an Association) mainly instrumental in securing the Act; but, alas! what a failure as a protective measure to legitimate practitioners!

It seems to me that, according to the decisions come to, any one may assume, without let or hindrance, the title of doctor or surgeon, and practise in any way he likes, provided he do not pretend or profess to be upon the registry. Even the slight barrier of the Apothecaries' Company will probably now be in abeyance.

My object, however, in writing this, is thus publicly to urge upon the Medical Council the propriety of seeking new powers to do away with this anomaly. Sir Charles Hastings is one of this body; and if he will kindly use the same eloquence and cogent arguments, in the Council, he has frequently done on former occasions, I do not despair of good coming of it.

I appeal to the Medical Council as the only body likely effectually to gain the ear of Parliament; and my firm conviction is that, if they will move in full conclave, they will not find much difficulty in securing an amendment of the Act.

I think petitions to Parliament from the Branches of the Association, or from the profession generally, would now have no effect. The Government would naturally say, "There is a governing body appointed by the Medical Act, what do they say?"

Let the public avail themselves of empiricism as much as they like; but surely the line of demarcation should be so clear that people may know whether they are employing legitimate practitioners or not. All I ask is, that a man should not be allowed to assume a title he does not legally possess.

I am, etc.,

JAMES HEYGATE, M.D.,

Vice-President of the British Medical Association.

Derby, March 2nd, 1863.

### MEDICAL HEALTH ASSURANCE OFFICES.

LETTER FROM JOHN M. BRYAN, M.D.

SIR,—Since my recent communication (with the insertion of which you favoured me in our JOURNAL), I have received letters from several gentlemen in different parts of the kingdom; showing that there is a widely spread interest in the subject of a Health Assurance Society. I have also received a pamphlet from an assurance company established in 1855, containing a sick benefit table, with scale of ages and payments, allowing £1 weekly, in case of sickness or incapacity, for the first six months; half benefit to 60 years of age; and one quarter after that time. For example: "For a person of 50 years of age, the annual premium would be £4:2"; so that I am disposed to think that with an

annual premium of £5, or rather more, a society might safely be established.

To this end, I should be happy to act *pro tempore*, and to receive the names of those gentlemen who might feel disposed to join, with the understanding that rules should be formed and satisfactory treasurer or treasurers and secretaries appointed; and it might then be seen how far it would be supported. I still think that it might be commenced and worked through the medium of the honorary secretaries of the British Medical Association, if those gentlemen would feel disposed so to act; and if you would kindly cooperate, and allow the names of correspondents to be inserted in the JOURNAL (and the valuable leading article you gave in last week's leads me to suppose you would do so) you would thereby be conferring a great benefit on those of the medical profession who are desirous at once to have an association formed.

I am, etc.,

JOHN M. BRYAN.

Northampton, March 2nd, 1863.

P.S. Perhaps those gentlemen who write to me personally, and desire an answer, will favour me with a stamped envelope addressed.

### MEDICAL HEALTH ASSURANCE.

LETTER FROM H. GRAMSHAW, ESQ.

SIR,—As a member of the British Medical Association, I feel indebted to you for calling attention to the question of medical health assurance in your leading article of the 28th ultimo. I do not wish to monopolise your space on the subject; and you have placed it so forcibly before a portion of the profession that surely it will come home to them; for to me it appears the want of the present day. Instead of being mulcted £2 each for a very doubtful advantage—to wit, registration—what a splendid investment that would have been towards a mutual medical health assurance society. The various professions have their various clubs; but the poor hard-worked doctor, spending much of his time in the pestiferous atmosphere of dirty courts and fever-stricken alleys, can boast of no friendly society of which he is a member. We form a great company of Poor-law medical officers; but we do not strike hand in hand for mutual aid and support; though of a surety there is no superfluity of salary that we can carry to the bank. And though I have seen a surgeon's children in the work-house, I cannot say I should like my own to be similarly provided for.

In my last note I mentioned Mr. Cubitt of Norwich. That gentleman was to have been the manager of a company called the East-Anglian Equitable Provident Insurance Society. The company was formed; the rules of the society and the tables of rates printed; but the scheme was not carried out because, owing to our legal code, any society of the sort must be a mutual one, or incur personal liabilities, to which no directors would consent. I now forward for your inspection the rules and tables to which I allude; also three letters from Mr. Cubitt to me on the subject; and I hope you will allow him to speak for himself as far as space will permit. He is thoroughly conversant with the subject, and it touches him personally, as he has a son who is not only in the profession, but an ornament to it.

In a scheme of health assurance, it becomes a question, are we to make it one that will provide against: 1. Sickness only? or 2. Sickness with a deferred annuity, commencing say at 60 or 65? or 3. Sickness with deferred annuity and life assurance also? The second scheme appears to me the best.

Any one interested in the matter will find much valuable information in Mr. Alexander Glen Finlaison's report, entitled *Friendly Societies Sickness and Mortality* (printed by House of Commons, Aug. 16th, 1853, price

1s.); also in a *Treatise on Life Assurance Societies and Friendly Societies*, by Arthur Scratchly, M.A., F.R.A.S. (Shaw and Sons, Fetter Lane); and *Observations on the Rate of Mortality and Sickness among Friendly Societies*, by Henry Ratcliffe (printed by George Falkner, King Street, Manchester).

I have only to remark, in conclusion, that the tables on which the East-Anglian Equitable Provident Insurance Society would have acted were approved by an eminent actuary; viz., Robert Tucker, Esq., London.

I am, etc.,

HENRY GRAMSHAW.

Laxfield Villa, near Framlingham, March 2nd, 1863.

To H. Gramshaw, Esq.

SIR,—My attention has been directed to your letter in the BRITISH MEDICAL JOURNAL of February 28th, on the subject of health insurance. I think it one of vital importance to nearly every class of the community; but to none so much as those whose incomes depend upon the power of healthy exertion. If I should be asked to select that profession which stands most in need of protection, or rather, whose moral duty it is to make provision against the hour of sickness, I should point to that of the medical world generally; but, in addition to this portion of the community, there is much fallow ground that requires to be worked. A wide and fertile expanse is before us, only requiring that culture which a common knowledge of statistics and prudential motives urging on to action offers not only a fair remuneration to investment, but would be the harbinger of comfort and consolation to thousands, when stretched on a bed of sickness.

It must not be supposed that your profession stands alone with regard to the need of this provision. The clergy, the commercial travellers, the clerks of various denominations, and a host of others, may and should be brought to guard against the contingency of sickness. Every one knows with what anxiety the day-labourer, the artisan, and the mechanic selects a club for this purpose. Others, in a better grade, make provision for their survivors by a life insurance; and, though many among the medical profession may have insured, yet even that provision is left in peril, should it unhappily occur that they are unable from sickness to continue their early avocations.

I am fully aware of the difficulty that presents itself to provide sufficiently against both contingencies (sickness and mortality); but the one is so intimately connected with the other, that they should generally be united.

Let us for a moment say that the first is deemed imperative; that the assured has only his professional income on which he can depend, and that not very ample. Years glide on with an even current, and his professional income barely meets the demand of a man who is by education and position a gentleman. Allowing that his income has been steadily improving, in all probability his family demands have increased in the same if not in a larger ratio, thus preventing any solid provision. The day of sickness comes at last, for come it will to all. No longer able to perform his wonted duties, he falls back, from necessity, on extraneous aid. Increased expense and diminished income are nearly the certain result. The foundation on which he might have relied has not been provided. The provision against sickness would have met the extra expenditure, kept in force the insurance upon his life, been a balm to his anxious feelings, and probably a valuable auxiliary to his recovery.

I need not attempt to describe in its entire result the consequence of not providing against sickness where much depends upon physical energy, a sound judgment, and the power of carrying conviction to the minds of others. In health alone can these powers be retained in full vigour. We cannot ward off the calamity, happily unseen by our feeble vision; but one thing most can do, and, if it be left undone, a duty is neglected,—we can by

care and frugality, by a reasonable restraint exercised over our inclinations, provide in the days of health that which would prove a rich harvest in the period of sickness.

I am, etc., G. CUBITT.

17, Market Place, Norwich, March 1863.

#### LETTER FROM GEORGE CUBITT, ESQ.

SIR,—Will you kindly permit me space for a few remarks relative to health insurances? It is with satisfaction that I see this question about to be agitated by a class of gentlemen whose intelligence and influence cannot be disputed. If I can be instrumental in promoting their views, as far as certified tables and regulations are concerned, I shall be happy to forward a copy of each to any address where they may be useful.

In addressing you at this time, my wish is to make a few observations relative to your remarks in the JOURNAL of February 28th. In suggesting the annual division of the surplus, to the reduction of future premiums, you would be taxing the society very heavily. During the early period of existence, you would not have attained a fair average in numbers; and hence deduction, apportioning profits on so short an experience, would be likely to mislead. The appropriation of the entire savings would be certain destruction, as the excess for cost of sickness as the age advances is far greater than the premium paid. There can be no doubt that a considerable reserve, during the first twenty-five years, is essential to the stability of the society in after years.

I feel that it would be unwise to confine insurances to medical men—decidedly not the best lives. The statistics on sickness are from combined employment; and, to be safe, I think it desirable that insurances should be accepted on the same basis. My own impression is, that the door should be opened wide, if you desire fully to meet the wants of the community. If your object is to satisfy only a clan or class, the scope is insufficient; if you desire to erect a superstructure worthy of commendation, you must have space sufficient. You have to treat with an enlightened public, and must act on liberal ideas.

The means as well as the requirements of the different grades are numerous, and utterly opposed to uniformity. This is, I think, a sufficient argument against confining the allowance to an uniform sum; and I confess I cannot discover an extra risk in accepting £5 per year for an allowance of £3 per week, as compared with £2:10 for one of thirty shillings.

If you confine your allowance to sickness only, it will, I fear, never take root. Our information on that head is insufficient beyond the age of sixty-five. *The future provision should, I think, be a deferred annuity, commencing at that time or before; all payments to the society ceasing when the annuity commences.*

I am, etc., G. CUBITT.

**EFFECT OF SYRUPS ON LINEN.** Dr. Dore has sent in a paper to the French Academy of Science on the effects of syrup dropped on linen. All syrups, and those of sugar especially, when dropped upon cotton or linen stuffs, and exposed to a moderate temperature, deprive these stuffs of their flexibility and tenacity, and the threads break very easily under their influence. At first sight, the rent has the appearance of having been produced by some corrosive substance, weak sulphuric acid, for instance. A similar effect is produced when wet linen is exposed to a certain degree of cold; the linen becomes brittle. Dr. Dore observes that it is highly important to notice such facts, because they might sometimes, in ignorant minds, generate suspicions injurious to the reputation of a chemist, or of a physician, or else furnish ill-disposed persons with a weapon against those who attend the sick.

## Medical News.

**ROYAL COLLEGE OF SURGEONS** The following members of the College, having been *elected* Fellows at previous meetings of the Council, were admitted as such on March 11th.

Barrow, Benjamin, Ryde, Isle of Wight: diploma of membership dated June 27, 1836

Cathrow, William, Weymouth Street, Portland Place: November 5, 1830

Gilson, John Thomas, Chelmsford: September 2, 1825

#### APPOINTMENTS.

ANDERSON, William, M.D., appointed Resident Physician and Medical Tutor to the Birmingham General Hospital.

BALDOCK, Stottfold, Esq., appointed Resident Apothecary to Bethlem Hospital.

COWELL, George, Esq., appointed Surgeon to the St. George's and St. James's Dispensary, in the room of W. F. Teevan, Esq.

DUKE, Stephen, M.D., appointed House-Surgeon to the Great Northern Hospital.

JONES, John, Esq., appointed House-Surgeon and Secretary to the Royal Isle of Wight Infirmary.

KRAGGS, S., Esq., elected Surgeon to the Huddersfield Infirmary.

NEWTON, Henry W. P., Esq., appointed House-Surgeon to the Chesterfield and North Derbyshire Hospital.

OLLARD, John F., Esq., appointed Medical Officer to the Royal Isle of Wight Infirmary.

FENTON, John, Esq., appointed Surgeon to the Liverpool Constabulary.

PINNIGER, Broome, Esq., appointed Medical Officer to the Royal Isle of Wight Infirmary.

POPE, John R., Esq., elected Surgeon to the East Sussex Infirmary.

RHODES, George W., Esq., elected Surgeon to the Huddersfield Infirmary.

SHEPHEARD, Philip C., Esq., appointed Assistant Medical Officer to the Three Counties Asylum.

\*SWIFT, Henry, Esq., appointed Surgeon to the Liverpool Constabulary.

TEEVAN, W. F., Esq., appointed Surgeon to the West of London Hospital.

WHITHAM, John, Esq., appointed House-Surgeon to the Male Lock Hospital.

#### POOR-LAW MEDICAL SERVICE.

ALLDAY, Francis, Esq., appointed Medical Officer of the Merthyr Tydfil Union Workhouse.

ELLISTON, Wm. A., M.D., appointed Medical Officer to the Claydon District of the Bosmere and Claydon Union, Suffolk.

GRIFFITHS, Griffith H., M.D., to be medical officer to No. 4 district of the Church Stretton Union.

HAMMOND, Samuel, L.R.C.P.E., to be medical officer to the first district of the Midhurst Union, Sussex.

KELLY, Frederick, Esq., appointed Medical Officer to the South District of the West London Union.

LAYCOCK, Robert, Esq., to be Medical Officer to No. 1 District and the Workhouse of the Bramley Union, Yorkshire.

MORRIS, John P., M.D., to be Medical Officer to the Heyford District of the Bicester Union.

NEWETT, Robert H., Esq., to be Resident Surgeon to the Belfast Union Workhouse.

PARK, James H., M.D., re-elected Medical Officer to the parish of Monifeth, Forfarshire.

WESTMACOTT, Joseph V. L., Esq., to be medical officer to the Ardwick district of the Charlton Union.

WIMBERLEY, Conrad C., M.D., appointed Medical Officer to the Bedworth District of the Foleshill Union, Warwickshire.

YATES, James, Esq., to be Medical Officer to the Newcastle District and Workhouse of the Newcastle-under-Lyme Union.

#### ARMY.

FORTEATH, Surgeon A. M.D., 1st Dragoon Guards, having completed twenty years full-pay service, to be Surgeon-Major.

#### ROYAL NAVY.

NIVEN, James, Esq., Surgeon, to the *Pembroke*.

#### MILITIA.

MACIAREN, P. H., M.D., to be Assistant-Surgeon Edinburgh County Militia.

#### VOLUNTEERS. (A.V.=Artillery Volunteers; R.V.=Rifle Volunteers):—

MOTT, Charles G., Esq., to be Surgeon 20th Middlesex R.V.

#### DEATHS.

CAUTLEY. At Hedon, Holderness, on March 4th, aged 61, Mary Ann, wife of \*Henry Cautley, Esq.

HOPKINS, Wm., M.D., at Boulogne-sur-Mer, aged 86, on March 6.  
LEWINS. On February 26th, at Clifton, the widow of the late Robert Lewis, M.D.  
\*PROWSE, John, Esq., at Nuneston, aged 43, on February 26.  
\*SIMPSON, Thomas, M.D., at York, aged 74, on February 23.  
VENABLES. On November 29th, 1862, at Melbourne, Australia, aged 31, the wife of George A. Venables, M.D.

THE DR. SEMPLE FUND. This fund is now closed. Upwards of £500 have been subscribed.

NEW ODONTOLOGICAL SOCIETY. The College of Dentists and the Odontological Society have united, and the society which they now form, has taken the title of "The Odontological Society of Great Britain."

BRITISH ORPHAN ASYLUM. The building of the British Orphan Asylum at Clapham Rise has been taken by the trustees of the Hospital for Incurables. One of the trustees, Mr. C. Wood, has promised an annual subscription to the charity of £300.

ROYAL EDINBURGH ASYLUM FOR THE INSANE. The president of the Royal College of Physicians, Edinburgh; the president of the Royal College of Surgeons, Edinburgh; Professor Simpson, Professor Syme, and Dr. David MacLagan have been appointed the medical board of the Royal Edinburgh Asylum for the Insane during the ensuing year; Dr. Skae has been appointed resident physician, and Drs. Clouston and Yellowlees assistant physicians.

FOREIGN ACONITINE. A correspondent of the *Chemical News* writes: "This alkaloid is generally regarded as a most powerful poison. The foreign article, however, I fancy is a comparatively harmless one. I gave a small dog three grains of a substance, labelled 'Pure Aconitina Exot.,' and obtained from a very respectable source, but it had not the slightest effect on the animal. A few days afterwards I gave three grains of another sample, not said to be 'exot.,' at least that was not on the label, and it was a very different looking article. This made the dog dreadful sick; he vomited and retched almost incessantly for more than an hour, and then he got better, and the next day was quite well."

MEDICAL SOCIETY OF LONDON. The ninetieth anniversary meeting of this society was held at the Albion Tavern, on the 7th instant. The annual oration was delivered by Dr. Habershon. A silver medal was presented to Mr. W. C. Calthrop, of Withern, Lincolnshire, for a paper on Spontaneous Closure of the Axillary Artery. There was no award of the Fothergillian medal. The following officers and council were elected:—President: E. Canton, Esq. Vice-Presidents: J. Bird, M.D.; T. Bryant, Esq.; C. J. Hare, M.D.; and G. Lawson, Esq. Treasurer: C. H. Rogers Harrison, Esq. Librarian: J. Palfrey, M.D. Secretaries in Ordinary: G. D. Gibb, M.D.; and E. S. Thompson, M.D. Secretary for Foreign Correspondence: V. de Méric, Esq. Councilors: J. Althaus, M.D.; R. Barwell, Esq.; J. Birkett, Esq.; W. Camps, M.D.; W. Cholmeley, M.D.; A. Clark, M.D.; J. Cockle, M.D.; T. C. W. Cooke, Esq.; W. Coulson, Esq.; T. Davidson, M.D.; S. O. Habershon, M.D.; A. Henry, M.D.; J. W. Hulke, Esq.; J. Jephson, M.D.; A. Leared, M.D.; H. P. Roberts, Esq.; F. Sibson, M.D.; W. Smiles, M.D.; J. S. Stocker, M.D.; J. Townley, Esq. Orator: H. Thompson, Esq. The proceedings terminated with a dinner.

DEATHS FROM NITRIC ACID. A very painful sensation has been caused in Edinburgh by the death of Mr. Stewart, one of the masters, and also of the janitor of the Edinburgh Institution, a large educational establishment in Queen Street. Mr. Stewart was in the laboratory of the school preparing for some chemical experiments, and while carrying a jar of nitric acid across the room, it fell on the floor and was broken. He called the janitor to his assistance to wipe the floor, and to endeavour to save a portion of the fluid. In this effort both unwittingly

inhaled its deadly fumes. Mr. Stewart went home to dinner unconscious of the injury he had received. After an hour or two he began to experience difficulty of breathing, and sent for medical advice, but he very rapidly became worse, and expired at two o'clock on Wednesday morning, about ten hours after the accident. The janitor was also taken ill, and, though he rallied for a time on Wednesday, he afterwards sank, and expired at five o'clock on Thursday morning. Several of the most eminent medical men in the city were called in to the unfortunate patients, but their skill proved unavailing.

DEATH OF A CHILD FROM CAMPHOR. A teaspoonful of camphorated oil was given by accident to a child at Peckham, two years old. The child soon after vomited twice; and then Dr. Griffith was sent for. The deceased was ordered to be put into a bath. She rallied at first, but died in thirteen hours. Dr. Griffith said at the inquest, that he went to the parents' house, and found the deceased in its mother's lap. He was informed what had taken place. The child was greatly convulsed. Owing to the jaws being fixed, he gave stimulating injections to the bowels, and applied mustard poultices to the spine and cold to the head. About twelve o'clock, on his next visit, he saw that the convulsions had ceased, and the pulse had resumed its regularity. Seven hours afterwards he found the child again terribly convulsed, and he detected a strong smell of camphor from the mouth. The child died at eleven o'clock. The bottle, labelled "camphorated oil," was brought to him the next day by the constable. The contents consisted of oil and camphor. Camphor taken in large quantities was injurious. It acted upon the nervous system. He considered that a teaspoonful of camphorated oil was too much to give to a child of a year and eight months old. Convulsions sometimes came on from natural causes. He could not say that the mixture had caused the death, although the symptoms were precisely the same as would be produced by camphor; but if it was the cause of death, it was the smallest dose on record known to destroy life. After some further evidence, the jury returned a verdict, "That the child had died from the administration of camphorated oil, given by misadventure and not from any design."

EXPENSE OF LIGHT. The comparative cost of light is shown in a table exhibiting the comparative cost of the light of twenty sperm candles, each burning ten hours, at the rate of 120 grains per hour:—

	s.	d.
Wax . . . . .	7	2½
Spermaceti . . . . .	6	8
Tallow . . . . .	2	8
Sperm oil . . . . .	1	10
Coal gas . . . . .	0	4½
Cannel gas . . . . .	0	3
Paraffin candles . . . . .	3	10
" oil . . . . .	0	6
Rock oil . . . . .	0	7½

Paraffin and rock oils are the best sources of light for domestic purposes, inasmuch as they give the largest amount of light with the least development of heat. The amount of carbonic acid generated, and heat evolved, per hour, in obtaining a light equal to twenty sperm candles, each burning 120 grains an hour, is as follows:—

	Carbonic acid in cubic feet.	Units of heat.
Tallow . . . . .	10·1	100
Wax . . . . .	8·3	82
Spermaceti } . . . . .	6·7	65
Paraffin . . . . .	5·0	47
Coal gas . . . . .	4·0	32
Cannel gas } . . . . .	3·0	29
Paraffin oil } . . . . .		
Rock " } . . . . .		

(Dr. Frankland. *Chem. News.*)

## OPERATION DAYS AT THE HOSPITALS.

MONDAY.....Royal Free, 2 P.M.—Metropolitan Free, 2 P.M.—St. Mark's for Fistula and other Diseases of the Rectum, 1.15 P.M.—Samaritan, 2.30 P.M.—Lock, Clinical Demonstration and Operations, 1 P.M.

TUESDAY.... Guy's, 1½ P.M.—Westminster, 2 P.M.

WEDNESDAY... St. Mary's, 1 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.

THURSDAY.... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—London, 1.30 P.M.—Great Northern, 2 P.M.—London Surgical Home, 2 P.M.—Royal Orthopaedic, 2 P.M.

FRIDAY..... Westminster Ophthalmic, 1.30 P.M.

SATURDAY.... St. Thomas's, 1 P.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY. Medical Society of London, 8.30 P.M. Clinical Discussion. The President, "A Case of Successful Excision of the Elbow-joint"; Dr. Greenhalgh; Dr. Abbott Smith; Dr. Gibb; and Mr. Henry Lee; and other communications.—Asiatic.

TUESDAY. Statistical.—Pathological.—Ethnological.

WEDNESDAY. Royal College of Physicians, 5 P.M. Dr. Chambers. Lumlilan Lectures. "Formation of Mucus and Pus."—Meteorological.—Society of Arts.—Geological.

THURSDAY. Zoological.—Royal.—Antiquarian.—Linnæan.—Chemical.—Harveian.

FRIDAY. Royal College of Physicians, 5 P.M. Dr. Chambers. Lumlilan Lectures. "Formation of Mucus and Pus."—Royal Institution.—Western Medical and Surgical, 8 P.M. Mr. Rouse will read a paper "On Rheumatic Iritis."

SATURDAY. Association Medical Officers of Health.

## POPULATION STATISTICS AND METEOROLOGY OF LONDON—MARCH 7, 1863.

[From the Registrar-General's Report.]

	Births.	Deaths.
During week.....	{ Boys .. 957 } { Girls .. 875 }	1832 1370

## TO CORRESPONDENTS.

\*. All letters and communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen St., Lincoln's Inn Fields, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

PHYSICIANS AND DOCTORS.—SIR: Sincerely desirous as I believe you are to be impartial in the expression of your opinion relative to Physicians and Doctors of Medicine, your sentiments, as enunciated in your various "leaders", are draped, so to speak, with the university "toga", from beneath which the cloven foot of impartiality for your first medical love, the University, incontinently peeps forth. Your "slaughter of the innocents", the poor suffering physicians, appears to be insatiable and somewhat indiscriminate; and, in your evident desire to chastise the Edinburgh fledglings of the year of "grace", you lay about you with such over-zealous goodwill as to prostrate the whole species beneath the force of your editorial ferule.

In simple justice, therefore, to the physicians who have obtained their diploma after a fair and legitimate examination, I would beg to ask why, if the title of "Dr." (accorded from ancient times) be disallowed, except as an act of courtesy, to physicians—the highest professional title recognised by the law—why should simple Doc-

tors of Medicine in so many instances assume, and affix to their signatures after the ebalistic letters M.D., the superior title of Physician to .... Hospital? to which they have no legal claim! Why, I would also ask, if, as your readers must inferentially conclude from the leader in the JOURNAL of the 21st ult., the title of Physician is to be regarded as inferior to that of M.D., did so many eminent pure and simple M.D.s—such as Sir H. Cooper, M.D. Univ. Lond.; W. H. Ranking, M.D. Cantab.; W. Ogle, M.B. Oxon.; and many others, seek admission into the London College during the year of grace? Would such men seek for an inferior title?

Again: How, if pure and legitimate "Physicians" are inferior to "Doctors of Medicine", is it that a student can or could graduate at the age of 21, but cannot present himself for examination at the Royal College of Physicians until he is of the mature age of 25 or 26, and after an extended period of practical study? As a Fellow of the College, you can probably throw a little light on the subject, and oblige  
Yours, etc., M.R.C.S.

February 28th, 1863.

[Our correspondent does not keep pace with the times. He regards the Doctorate and the Physician's License from a twenty-years ago point of view. But these things have been revolutionised since the year of grace. He ignores, moreover, the fact that physicians have been of late years made by the score, and are still being made, at the mature age of 21. We were quite unaware of having said anything to exalt the Doctorate over the License, or the License over the Doctorate. The fact is, there are physicians and physicians, and there are doctors and doctors. No doubt that a physician made at 21 and a physician made at 25, are made under different conditions; but they are nevertheless both physicians in the eye of the law. We may say of them, as Lord Dunsyre does of woman: One physician is as good as another—perhaps better. But members made at 25, and licentiates made at 21, are still equally physicians. EDITOR.]

CONSULTATIONS WITH NON-REGISTERED PRACTISERS OF MEDICINE.—SIR: In my letter to you concerning the non-registered medical practitioner, I said a "physician of high repute had met him in consultation." As you seem to doubt it, I hardly know whether to give names or not. It will look personal if I do; as I have been for twenty years a personal friend of one. I can only repeat that the practising doctor I was first asked to meet in a case; on my declining, a physician (magistrate and mayor) did. Not but what he did the thing adroitly; after meeting him twice or so, he gave him the cold shoulder, and took the case himself. The other would, I fear, be a more serious charge, and, of course, would be a painful case to inquire into, and in which I should be one of the last to proceed; because it would turn upon the question, Is a physician, sent for urgently, to refuse going, because a non-registered man is attending? It must come to that; although I have no more doubt myself that the physician knew as well as I know the circumstances, and whom he was to meet.

I regret to say that the physician has held a distinguished post in our Association, and that the consultations have been more than once.

If it would serve any purpose, I am happy to give the whole of the names; but I do not see that it would. I am, etc.,

March 10th, 1863.

AN OLD ASSOCIATE.

COMMUNICATION OF SYPHILIS BY THE BLOOD. M. Vienneu insists on the contagious character of the blood of syphilitic patients, which is denied by Ricord, who says:—"It is very remarkable that the blood, which evidently serves as the vehicle of the poison, and which is itself subjected to the influence of syphilis, does not possess any contagious quality, and cannot communicate the disease to a healthy person."

COMMUNICATIONS HAVE BEEN RECEIVED FROM:—DR. THOS. KING CHAMBERS; MR. CATTLEY; DR. HARDWICKE; MR. J. BARKER; MR. NEVINS; AN OLD ASSOCIATE; MR. HUGH NORRIS; MR. BENJAMIN THOMAS; MR. J. VOSE SOLOMON; DR. T. J. WALKER; MR. THOMAS BRYANT; DR. LIONEL BEALE; THE REGISTRAR OF THE MEDICAL SOCIETY OF LONDON; DR. ROBERT H. POWELL; THE HONORARY SECRETARY OF THE WESTERN MEDICAL AND SURGICAL SOCIETY; MR. G. F. BODINGTON; MR. T. M. STONE; MR. RIVINGTON; MR. HAYNES WALTON; and MR. BENJAMIN THOMAS.

## BOOK RECEIVED.

The International Aspect of Quarantine Legislation. By Gavin Milroy, M.D.

**A Gentleman, aged 34, is open** to an immediate RE-ENGAGEMENT. He has had considerable practical experience in all branches of the Profession. First-class references and testimonials as to moral character and professional capability.—Address J. M., Post Office, York.

**Royal Medical Benevolent College, EPSOM.**—Notice is hereby given, that no applications on behalf of persons desirous to become candidates for admission to the College as FELLOWS or FOUNDATION SCHOLARS at the next ensuing Election can be received by the Council after the Morning of the 18th of March inst., when the list of candidates will be finally closed, in order that the Balloting Papers may be printed. The Election will take place, as usual, in May.

By order of the Council,

ROBERT FREEMAN, Secretary.

Office, 57, Sobo Square, London, March 4, 1863.

**Royal College of Physicians OF LONDON.**—FIRST PART OF THE PROFESSIONAL EXAMINATION FOR THE LICENCE. The next Examination of Students who have completed their Second Winter Session of Study at a recognised Medical School will commence on Tuesday, April 7th.

SECOND PART OF THE PROFESSIONAL EXAMINATION.—An Examination of Gentlemen who are eligible for admission to the Second Examination for the Licence will commence on Tuesday, April 14th.

Registered Medical Practitioners qualified before January 1861, are admitted to Examination under special Bye-Laws.

Candidates are required to give fourteen days notice in writing to the Registrar of the College, with whom all Certificates and Testimonials required by the Bye-Laws are to be left at the same time.

H. A. PITMAN, M.D., Registrar.

Pall Mall East.

**Royal College of Surgeons of ENGLAND.**—Notice is hereby given that PRIMARY or ANATOMICAL EXAMINATIONS for the Diploma of Member of this College will commence on the 4th, 11th, and 25th of April next respectively.

Certificates from Students completing their Anatomical Studies at the termination of the present Winter Session must in ALL CASES BE TRANSMITTED THROUGH THE POST not earlier than the 31st of March next.

And that PASS or SURGICAL EXAMINATIONS will commence on the 18th of April and 2nd of May next, respectively.

Certificates from Students completing the Curriculum of this College at the termination of the present Winter Session must in ALL CASES BE TRANSMITTED THROUGH THE POST not earlier than the 4th of April next.

Particulars relating to these Examinations may be obtained at the College.

25th February, 1863.

EDMUND BELFOUR, Secretary.

**Apothecaries' Hall.**—The next EXAMINATION in ARTS will be held at the Hall, on FRIDAY and SATURDAY, the 24th and 25th of April, 1863. A Syllabus of the Subjects for Examination may be had on application. An Examination in Arts will again be held in the month of September 1863.

R. B. UPTON, Clerk to the Society.

**Volunteer Service and General ASSURANCE ASSOCIATION.**

FIRE, LIFE, ENDOWMENTS, ANNUITIES, LOANS: And (financially distinct from the Association) an "ACCIDENT FUND" FOR VOLUNTEERS.

Capital: £250,000.

Chief Office: 8, ST. MARTIN'S PLACE, CHANCING CROSS, LONDON.

Trustees—EARL SPENCER; EARL DE GREY AND RIPLEY; EARL GROSVENOR, M.P.; LORD ELCHIN, M.P.

Directors—Chairman: VISCOUNT BURY, M.P. Deputy Chairman: MACLEOD OF MACLEOD.

MEDICAL REFEREES are paid by the Office. Medical cooperation is requested.

PROSPECTUSES OF THE FIRE AND LIFE DEPARTMENTS, and of the "VOLUNTEER ACCIDENT FUND" will be forwarded on application being received.

JOHN ROSE CORMACK, Manager.  
8, St. Martin's Place, Chancing Cross, W.C.

Now ready, price 6d., by post 7d.

**The Addresses delivered at the THIRTIETH ANNUAL MEETING of the BRITISH MEDICAL ASSOCIATION, held in the Royal College of Physicians in London, on August 5th, 6th, 7th, and 8th.**

London: THOMAS RICHARDS, 37, Great Queen Street, W.C.

**Peroxide of Hydrogen. (The New Medicinal Agent.)** According to the formula, and of the strength described by Dr. Richardson in a paper read before the Medical Society.

See *British Medical Journal*, March 22, and other Medical Journals. Price 4s. 6d. per lb.

Prepared by A. GARDEN, Operative Chemist, 372, OXFORD STREET, LONDON.

**Liquor Bismuthi, (Schacht)—a** fluid preparation of Bismuth, not decomposed by dilution. This article has been extensively used at the Bristol General Hospital, and in private dispensing, since 1857; and is recommended by many of the faculty as more efficacious and more convenient of administration than any other form of the remedy.

Prepared by G. F. SCHACHT, Chemist, Clifton.

London Agents: Messrs. DRIFW, BARRON, & CO., Bush Lane, and Messrs. SAVORY & MOORE, New Bond Street.

**SAMUEL HIGHLEY'S SCIENTIFIC EDUCATIONAL MUSEUM**

Is open, Admission Free, between 10 and 4 Daily;

AND

**THE EXHIBITION**

OF

**SCIENCE AND ART PHOTOGRAPHS**

FOR THE MAGIC LANTERN,

As shown before the Society of Arts with great élat, every Evening at Eight.

Stalls, 3s. Area, 2s. Back Seats, 1s.

BURLINGTON GALLERY, 191, PICCADILLY.

**Jozeau's Copahine Mege.**

Or SACCHARATED CAPSULES. — Copahine and Cubebs are doubtless the best remedies, but these drugs are of a repulsive taste and odour, and occasion colicky pains, nausea, and gastric disturbance. M. Jozeau has succeeded in rendering these valuable therapeutic agents perfectly innocuous, by increasing, in his Copahine, all the curative properties. This preparation has been adopted by the Paris Academy of Medicine, after more than a thousand trials in Paris, and the different London Hospitals, viz., St. Thomas's, Guy's, and St. Bartholomew's, under the care of Messrs. Lloyd, Poland, and Le Gros Clark. "Lancet" Nov. 6, and Dec. 10, 1852. The Copahine which is in form of a pretty pink sugar-plum, effects a cure in about six days, either in recent or chronic diseases. 100 Capsules, 4s. 6d. at G. JOZEAU'S, French Chemist, 49, Haymarket, London; 22, Rue St. Quentin, Paris; and all the most important Chemists.

TO SURGEONS, APOTHECARIES, AND DRUGGISTS.

**Important Saving, by Prepayment, in the PURCHASE of NEW WHITE ROUND MOULDED VIALS OF THE BEST QUALITY.**

PELLATT and Co. submit the following PRICES of VIALS, for PREPAYMENT only:—

1/2 oz., 1 oz., 10 dr., & 1 1/2 oz. per Gross, 6s.	In quantities of not less than Six Gross, assorted to suit the convenience of the purchaser, delivered to carriers in London.
14 dr., & 2 oz. " 7s.	
4 oz. " 8s.	
4 oz. " 10s.	
6 oz. " 15s.	
8 oz. " 18s.	
4 1/2 oz. graduated in 3 doses 12s. 6d.	No charge for Package.

Breakage at risk of Purchaser.

The above Prices being based upon a calculation which excludes all charges whatever between the Manufacturer and the Consumer, no attention can be paid to any order not accompanied by a remittance in full made payable in London.—P. and Co. do not supply Green Glass.—Orders and remittances to be addressed,

PELLATT & CO.,  
FALCON GLASS WORKS, LONDON.

**The Social Science Review.** Every Saturday, price 3d.

OFFICE—10, WHITEHALLS STREET, FLEET STREET, E.C.
